1832

ELASTICITY OF FLUIDS is accounted for from their particles being all endowed with a centrifugal force; when Sir Isaac Newton (prop. xxxii. lib. 2.) demonstrates, that particles, which naturally avoid or fly off from one another by such forces as are reciprocally proportioned to the distances of their centre, will compose an elastic fluid, whose density shall be proportional to its compression; and vice versa, if any fluid be composed of particles that fly off and avoid one another, and hath its density proportional to its compression, then the centrifug [redacted] of those particles will be reciprocall [redacted] distances of their centres.

ELASTICITY OF THE AIR is the for [redacted] with that element dilates itself, upon [redacted] the force whereby it was before [redacted] See AIR and ATMOSPHERE. The [redacted] spring of the air was first discovere [redacted] Its existence is proved by this experiment of that philosopher:—An extraordinary quantity of air being intruded by a syringe into a hollow glass or metal ball, till the ball, with this accession of air, weighs considerably more in the balance than it did before; upon opening the mouth thereof, the air rushes out, till the ball sink to its former weight. From hence we argue, that there is just as much air gone out, as compressed air had been crowded in. Air, therefore, returns to its former degree of expansion, upon removing the force that compressed or resisted its expansion; consequently it is endowed with an elastic force. It must be added, that, as the air is found to rush out in every situation or direction of the orifice, ie elastic force acts every way, or in every di-ection. The doctrine of the elasticity of the ir is a considerable branch of pneumatics. The ause of this elasticity has been commonly as-ribed to a repulsion between its particles; but is can give us only a very slight idea of the ature of its elasticity. The term repulsion, like iat of attraction, requires to be defined; and in ll probability will be found in most cases to be ie effect of the action of some other fluid. hus, we find, that the elasticity of the atmo-here is very considerably affected by heat. upposing a quantity of air heated to such a gree as is sufficient to raise Fahrenheit's ther-ometer to 212°, it will then occupy a consider-ble space. If it is cooled to such a degree as to nk the thermometer to 0°, it will shrink up into ss than half its former bulk. The quantity of pulsive power, therefore, acquired by the air, ile passing from one of these states to the er, is evidently owing to the heat added to or en away from it. Nor have we any reason to ppose, that the quantity of elasticity, or repul-power, it still possesses, is owing to ... supposing repulsion to be a primary cause, inde-pendent of all others, has given rise to man erroneous theories, and been one very gre mean of embarrassing philosophers in their ac-counting for the phenomena of electricity.

ELATE, *adj.* & *v.a.* } Lat. *elatus*, part. of ver
ELA'TION, *n. s.* } *effero*, to exalt, &c.; from *e*, forth, and *fero*, *latum*, to bring. Elevated; lofty; flushed with station or dignity. The verb seems to be derived from the adjective.

> This king of kinges proud was and elat [redacted]
> Thus with new taunts insult the monster's ear.
>
> *Id. Odyssey.*

> Or truth, divinely breaking on his mind,
> *Elates* his being, and unfolds his power.
>
> *Thomson.*

> Fair was the blossom, soft the vernal sky:
> *Elate* with hope we deemed no tempest nigh:
> When lo! a whirlwind's instantaneous gust
> Left all its beauties withering in the dust.
>
> *Beattie.*

ELATE, in botany, a genus of the monœc order and triandria class: CAL. none; COR. tr petalous, with three stamina or with one pistil FRUIT an oval acuminated plum. Species on only, an Indian tree.

ELATER, in zoology, a genus of insect belonging to the order of coleoptera. The an tennæ are setaceous; and an elastic spring spine projects from the hinder extremity of th breast or under side of the thorax. By means this kind of spring, the animal, when turne upon its back, contrives to leap up into the ai and so turn itself. It varies in size; and whe the insect is young, and newly metamorphosed its elytra are of a beautiful deep red; but in few days they change to a much darker hue, an are nearly of a chestnut color. In the state larvæ it inhabits the trunks of decayed trees, an is there transformed. With the help of its wing it issues from its prison, flutters upon flowers wanders over the fields, and conceals itself thickets or under the bark of trees.

ELATERIUM, *n. s.* Lat. An inspissated juice, light, of a friable texture and an acid an pungent taste. It is procured from the fruit a wild cucumber. It is a very violent and rou purge.

ELATERIUM, Ἐλατηριον, in botany, a genus the monandria order, monœcia class of plants natural order thirty-fourth, cucurbitaceæ, male o

inferior, unilocular, and bivalved. Species one only, a common plant.

ELATH, or ELOTH, in ancient geography, a part of Idumæa, situated upon the Red Sea, which David in his conquest of Edom took, 2 Sam. viii. 14, and there established a trade to all parts of the world. Solomon built ships in Elath, and sent them thence to Ophir for gold, 2 Chron. viii. 17, 18. It continued in the possession of the Israelites about 150 years, till the time of Joram, when the Edomites revolted and recovered it, 2 Kings viii. 20; but it was again taken from them by Azariah, and by him left to his son; 2 Kings xiv. 22. In the time of his grandson Ahaz, however, Rezin king of Syria took it, Ib. xvi. 6; and the Syrians kept it long; till after many changes, under the Ptolemies, it came at last into the possession of the Romans.

ELATINE, in botany, a genus of the tetragynia order and octandria class of plants; natural order fifteenth, inundatæ: CAL. tetraphyllous; the petals four: CAPS. [illegible]locular, quadrivalved, and depres[illegible] natives of the south of Europe.

ELATOSTEMA, [illegible] a genus of the pentandria order and [illegible] class of plants; male and fem[illegible] CAL. [illegible] COR. [illegible]partite; the stamina are fiv[illegible] filaments [illegible] CARP. a very small oblong, bi[illegible] [illegible]ous capsule: SEEDS single and [illegible]-shap[illegible].

ELBA, a small island of the Mediterranean, near the coast of Tuscany, in circuit about sixty miles. Its breadth is very various; its general aspect is mountainous, and its climate mild. Here are cultivated fruits, vines, corn, and maize. The horned cattle are few, the live stock being composed of horses and mules. The exports consist of wine, fruit, and iron ore, for which the island has been noted since the days of Virgil (Æn. x. 173); there are also mines of copper, and extensive quarries. It was in 1801 vested in the possession of Tuscany, and has acquired historical celebrity as the residence of Buonaparte from May 1814 to 26th February 1815, when he sailed on his last expedition to France. It has two harbours, Porto Ferrajo, the capital, and Porto Longone. The former is remarkable for the gallant defence which was made of it, by the English against the French in 1801. Elba reverted to the grand duke of Tuscany, after the departure of Napoleon. Population about 14,000. Several islets around it are uninhabited. Long. of Porto Ferrajo, 10° 19′ 35″ E.; lat. 42° 49′ 6″ N.

ELBE, a large river of Germany, anciently the Albis, which, rising on [illegible] of Silesia, runs through Bohem[illegible] Upper Saxony, Anhalt, Magdebur[illegible], and Danneberg; and afterward[illegible] duchy of Lunenburg from that of [illegible] well as that of Bremen from Ho[illegible] the German Ocean, about sevent[illegible] burgh. It is navigable for grea[illegible] any other river in Europe, and [illegible] Magdeburg and Hamburgh 50[illegible] navigation up to Hamburgh is dif[illegible]nt of numerous sand banks, and the [illegible] violence of the wind; particularly the westerly winds which increase the bulk of the waters, and cause inundations; an easterly wind on the other hand sometimes presses its waters to the sea, and deprives the canals dependent on it of the necessary supplies. Its navigation has likewise been much impeded by the tolls imposed by the princes of the different provinces through which it passes, there having been more than thirty between Pirna in Saxony, and Hamburgh; but this has been greatly remedied of late.

ELBERFELD, a thriving town on the Wupper, in the province of Berg, district of Dusseldorf, Prussia. The manufactures of Siamoise, lace, riband, linen, and stuffs, employ the greater part of a population of 18,000 persons. Here are also hardware and bleaching establishments of considerable extent. It is eighteen miles east of Dusseldorf, and twenty north-east of Cologne.

ELBERT, a county of Georgia, on the tract of land between Tugulo and Broad rivers. The south-east corner of the county is at their confluence; on the north-west it is bounded by Franklin county. The chief town is Petersburgh.

ELBING, a trading city of Polish Prussia, in the circle of Marienburg, situated in a fruitful level, on a bay of the Baltic Sea, called the Frischaff, or Erische Haffe, near the mouth of the Vistula. The town is large, populous, and very well built. It is divided into the old and new town, which were once well fortified, but in 1772 the works were demolished. The old town has a handsome tower, with a good college. The stadthouse and the academy are fine buildings, with pleasant gardens. The best warehouses are in the suburbs. No vessels larger than 100 tons burden can approach the town; but Elbing has a good export trade in corn potash, linen, butter, and cheese; and supplies from its manufactories considerable quantities of soap, starch, oil, and tobacco to the neighbourhood. Population 16,800. It is thirty miles south-east of Dantzic, and 100 north by west of Warsaw.

ELBOEUF, a thriving manufacturing town of France, on the Seine, in Normandy. There has been a celebrated manufacture of woollen cloths here since 1667; it has also manufactures of carpets and stockings. Ten miles south of Rouen, and sixty-five north-west of Paris.

EL'BOW, *n. s.*, *v. a* [illegible] *v. n.*
EL'BOW-CHAIR, *n. s.*
EL'BOW-ROOM. } Sax. elboȝe, from elb, an ell, and boȝen, bending, the ell being originally the length of the arm, and the bend being then at the elbow. The first joint of the arm below the shoulder; any angle. As a verb active, to push with the elbow; hence, to encroach upon; to drive. As a neuter verb, to point outwards in angles; to clash with. An elbow-chair is one that accommodates the elbows: elbow-room, room to extend the elbows; space enough to act in.

> Straight will he come;
> Wear thy good rapier bare, and put it home:
> Quick, quick; fear nothing, I'll be at thy *elbow*.
> *Shakspeare. Othello.*

> Now my soul hath *elbowroom*;
> It would not out at windows nor at doors. *Id.*

Fruit trees, or vines, set upon a wall between *elbo*[illegible]

or buttresses of stone, ripen more than upon a plain wall. *Bacon.*

The natives are not so many, but that there may be *elbowroom* enough for them, and for the adventives also. *Id.*

His sleves half hid with *elbow* pinionings,
As if he meant to flie with linnen wings.
*Bp. Hall. Satires.*

He that *elbows* in all his philosophic disputes must needs be very proud of own sufficiencies.
*Mannyngham.* 1631.

If fortune takes not off this boy betimes,
He'll make mad work and *elbow* out his neighbours.
*Dryden.*

A politician must put himself into a state of liberty to provide *elbowroom* for conscience to have its full play in. *South.*

What would you say should you see the sparkler shaking her *elbow* for a whole night together, and thumping the table with a dice-box?
*Addison. Guardian.*

Swans and *elbowchairs*, in the opera of Dioclesian, have danced upon the English stage with good success. *Gay.*

In some fair evening on your *elbow* laid,
You dream of triumphs in the rural shade.
*Pope.*

But *elbows* still were wanting; these, some say,
An alderman of Cripplegate contrived;
And some ascribe the' invention to a priest,
Burly, and big, and studious of his ease.
*Cowper.*

And at his *elbow*, souter Johnny,
His ancient, trusty, drouthy crony;
Tam lo'ed him like a vera brither;
They had been fou for weeks thegither.
*Burns.*

And thus upon his *elbow* he arose,
And looked upon the lady in whose cheek
The pale contended with the purple rose,
As with an effort she began to speak. *Byron.*

ELBOW, that eminence whereon the arm rests, is by the Latins called cubitus, and the Greeks αγκων and ολεκρανον. See ANATOMY.

ELCESAITES, in church history, a sect of heretics, who appeared in the reign of Trajan. They worshipped one God, observed the Jewish sabbath, circumcision, and the other ceremonies of the law; but they rejected the Pentateuch, the prophets, and the writings of the apostles, particularly those of St. Paul.

ELCHE, a large town of Spain, in the province of Valencia, situated in a plain, abounding with palm trees. It was the Illici of the Romans, and has still an ancient ducal palace. It has also some good streets and squares, but its general aspect is dull. The great church is a fine building, with a noble dome, and the barracks extensive and well built. There are here several poor houses and convents; the man[illegible]factures are confined to soap and leather, whic[illegible] with dates, palms, and other fruit of the nei[illegible]bourhood, constitute its articles of trade. [illegible] has several marble fountains. Population 18,[illegible]

ELD, *v.a.*, *v.n.* & *n.s.*
EL'DER, *adj.* & *n. s.*
EL'DERLY, [illegible]*v.*
EL'DERSH[illegible], *n. s.*
EL'DEST[illegible]

Sax. ealð; Scot. Goth. *ald*, from 'the [illegible]. verb ylðan, or ılðan, to remain, stay, continue, last, endure, delay, defer,' says Mr. Tooke, 'of which it is the past participle.' Chaucer uses eld, however, both as a verb active and neuter: see below: as a substantive, it signifies old age; decrepitude; and hence, old people. It is clearly the parent of our adjective OLD, which see, and in elder, eldest, we retain the original comparative and superlative. Elder, as a substantive, expresses seniority of age or office: it is also the name of a tree. Eldership is seniority, primogeniture. Elderly, approaching old age.

Elizabeth thi cosyn,—sche also hath conseyved a sone in hir *celde*, and this monethe is the sixte to hir that is clepid bareyn. *Wiclif. Luke* i.

[illegible] *elder*, but intreat him as a father, [illegible] men as brethren. 1 *Tim.* v. 1.

[illegible] time eke that ychaungith all,
[illegible] all doth waxe and fostrid be,
[illegible] alle thing destroith he;
The time that *eldith* our ancestours,
And *eldith* kings and emperours.
*Chaucer. Romaunt of the Rose.*

The time that hath alle in welde
To *elden* folke had made her *elde*. *Id.*

For *elde* is comen unwarely upon me, hasted by the harmes that I have, and sorowe hath commaunded his [illegible] be in me. *Colvile.*

[illegible] with joy unwonted inly sweld,
[illegible] comfort in her weaker *eld*.
*Spenser. Faerie Queene.*

[illegible] very superstitious and diligent obser[illegible]s, which they received by continual [illegible] from their parents, by recording of their bards and chronicles, in their songs, and by daily use and ensample of their *elders*.
*Id. Ireland.*

At the board, and in private, it very well becometh children's innocency to pray, and their *elders* to say Amen. *Hooker.*

The controversy sprang up between Beza and Erastus, about the matter of excommunications, whether there ought to be in all churches an *eldership*, having power to excommunicate, and a part of that *eldership* to be of necessity certain chosen out from amongst the laity. *Id.*

Thy blazed youth,
Becomes assuaged, and doth beg the alms
Of palsied *eld*. *Shakspeare.*

Let still the woman take
An *elder* than herself; so wears she to him,
So sways she level in her husband's heart. *Id.*

Our *elders* say,
The barren, touched in this holy chase,
Shake off their steril curse. *Id.*

We will establish our estate upon
Our *eldest* Malcolm, whom we name hereafter
The prince of Cumberland. *Id.*

Among the Lacedemonians, the chief magistrates, as they were, so were they called, *elder* men.
*Raleigh.*

[illegible]unkenness] possesseth a man, the [illegible] in it, and the *elder* he groweth [illegible] subject to it. *Id.*

[illegible] youth their virtuous awe disclose,
[illegible] their seats the reverend *elders* rose.
*Sandys.*

He thought it touched his deity full near,
If likewise he some fair one wedded not,
Thereby to wipe away the' infamous blo[illegible]
Of long uncoupled bed and childless *eld*.
*Milton.*

The *elder* of his children comes to acquire a degree of authority among the younger, [illegible] the same means the father did among them. *Temple.*

The mother's and her *eldest* daughter's grace,
It seems, had bribed him to prolong their space.
*Dryden.*

That all should Alibech adore, 'tis true:
But some respect is to my birthright due:
My claim to her by *eldership* I prove. *Id.*

Nor were the *eldership*
Of Artaxerxes worth our least of fears,
If Memnon's interest did not prop his cause.
*Rowe.*

Says the goose, If it will be no better, e'en carry your head as your *elders* have done before you.
*L'Estrange.*

*Eldest* parents signifies either the oldest men and women that have had children, or those who have longest had issue. *Locke.*

Flea-bitten synod, an assembly brewed
Of clerks and *elders* ana; like the rude
Chaos of presbytry, where laymen ride
With the tame woolpack clergy by their side.
*Cleveland.*

The branches are full of pith, having but little wood: the flowers are monopetalous, divided into several segments, and expand in form of a rose: these are, for the most part, collected into an [illegible]el, and are succeeded by soft succulent berries, [illegible]g three seeds in each. *Mill[illegible]*

They count him of the green-ha[illegible]
Fame's high temple sta[illegible]
Stupendous pile; not reared by [illegible]
Whate'er proud Rome, or artful [illegible]
Or *elder* Babylon, its frame excelled. [illegible]*pe.*

I lose my patience, and I own it too,
Where works are censured, not as bad, but new;
While, if our *elders* break all reason's laws,
Those fools demand not pardon but applause. *Id.*

With musing-deep, astonished stare,
I viewed the heavenly-seeming fair;
A whispering throb did witness bear,
Of kindred sweet,
When with an *elder* sister's air
She did me greet. *Burns.*

ELDER, in botany. See SAMBUCUS.

ELDERS, or SENIORS, in ancient Jewish polity, were persons the most considerable for age, experience, and wisdom. Of this sort were the seventy men whom Moses associated with himself in the government; such, likewise, afterwards were those who held the first rank in the synagogue, as presidents.

ELDERS, in the Presbyterian discipline, are officers, who, in conjunction with the ministers and deacons, compose the kirk-session, which formerly used to inspect and regulate matters of religion and discipline; but whose principal business now is to take care of the poor's funds. They are chosen from among the people, and are received publicly with some degree of ceremony. In Scotland, there is an indefinite number of elders in each parish; generally about twelve.

When a vacancy happens, it is filled up by an election made by the remaining members of the session. There is no legal limitation of the number of elders: but the general understanding is, that they are not to be multiplied unnecessarily, and as their office is a gratuitous one, and is attended with some little trouble, there is never much temptation to increase them, except when there is some particular point to be carried. They are commonly selected out of that respectable class of persons who are above the lower orders, and yet rather below the higher rank of the society c the place, though there is no definite rule, an no absolute exclusion of any body, whose cir cumstances and character are respectable. Th heritors are the proprietors of the real property within the parish. It is by them and thei tenants that the sum raised for the maintenance of the poor, called the assessment, must be paid. This assessment is divided between the proprietors, and the tenants, according to rules which it is needless to explain here; but the general import of which is, that the proprietors are entitled to obtain relief of what is laid upon them, to the extent of one-half, from their lessees. These heritors are conjoined with the kirk-sessions, in the administration of the poor's funds; that is, they are legally entitled to act along with them, but, as the first report by the general assembly states, 'the heritors, in practice, seldom or never interfere in regulating the concerns of the poor or the poor's funds, except in parishes where assessments are levied.' The ordinary funds for the support of the poor, consist of the alms collected at the church door, parochial fines, and other dues, and any sum that may have been gifted to [illegible] parish. The last are commonly small; so [illegible]he chief fund arises from the church-door [illegible]ollections. The direct tax, called an assessment, is only resorted to when these resources fail. It is in this apparatus that the excellence of the Scottish system is said to consist.

The elders are held to be a class of persons admirably fitted for investigating every claim that can be made for admission upon the poor's-roll. They reside within the parish; they either know the claimant personally, or can easily inquire into his character and circumstances; and they are in that station of life to which such an employment, instead of being nauseous, is a fair ground of parochial power and importance.

ELEATIC PHILOSOPHY, among the ancients, a name given to that of the stoics, because taught at Elea.

ELEATIC SECT. The founder of this sect of philosophers is supposed to have been Xenophanes, who lived about the fifty-sixth Olympiad, or about A. A. C. 350. It was divided into two parties, which may be denominated metaphysical and physical; the one rejecting, and the other approving, the appeal to fact and experiment. Of the former kind were Xenophanes, Parmenides, Melissus, and Zeno of Elea. They are supposed to have maintained principles similar to those of Spinoza; they held the eternity and immutability of the world; that whatever existed was only one being; that there was neither any generation nor corruption; that this one being was immoveable and immutable, and was the true God; and whatever changes seemed to happen in the universe, they considered as mere appearances and illusions of sense. However, some learned men have supposed, that Xenophanes and his followers, speaking metaphysically, understood by the universe or the one being, not the material world, but the originating principle of all things, or the true God, whom they expressly affirm to be incorporeal. Thus Simplicius represents them as merely metaphysical writers, who distinguished between things

natural and supernatural; and who made the former to be compounded of different principles. Accordingly, Xenophanes maintained, that the earth consisted of air and fire, that all things were produced out of the earth, and the sun and stars out of clouds, and that there were four elements. Parmenides also distinguished between the doctrine concerning metaphysical objects, called truth, and that concerning physical or corporeal things, called opinion; with respect to the former, there was one immoveable principle, but in the latter two that were moveable, viz. fire and earth, or heat and cold; in which particulars Zeno agreed with him. The other branch of the Eleatic sect were the atomic philosophers, who formed their system from an attention to the phenomena of nature; of these the most considerable were Leucippus, Democritus, and Protagoras.

ELECAMPA'NE, *n. s.* Lat. *helenium.* A plant, named also starwort. Botanists enumerate thirty species of this plant.

The Germans have a method of candying *elecampane* root like ginger, to which they prefer it, and call it German spice. *Hill's Materia Medica.*

ELECAMPANE, in botany. See INULA.

ELECT, *v. a., n. s.,* & *adj.*
ELEC'TION, *n. s.*
ELEC'TIONEERING,
ELEC'TIVE, *adj.*
ELEC'TIVELY, *adv.*
ELEC'TOR, *n. s.*
ELEC'TORAL, *adj.*
ELEC'TORATE, *n. s.*
ELEC'TORESS,
ELEC'TRESS.

Fr. *elire*; Ital. *eleggere*; Span. *elegir*; Port. *eleger*; Lat. *electus, eligere.* To choose; select: used, theologically, for God's choice of his Son, the Jews, Christians, &c.: and in the same sense, as a substantive, for the party or parties chosen. An election, politically, is the ceremony of choosing, or too often of returning only, members of parliament: electioneering, the business, solicitations, or practices, whereby such returns are procured: elective, regulated, or bestowed, by election; exerting choice: elector, one who has a right, or power, to choose to office, or otherwise: electoral, having the right or dignity of elector, applied, in a particular sense, to certain German princes, who[illegible]dominions are called their electorate: electoress, or electress, is the wife, or widow, of an electoral prince.

Behold my servant whom I uphold, mine *elect* in whom my soul delighteth. *Bible. Isa.* xlii. 1.

Who shall lay any thing to the charge of God's *elect?* *Id. Rom.* viii. 33.

If the *election* of the minister should be committed to every several parish, do you think that they would chuse the meetest? *Whitgift.*

You have here, lady,
And of your choice, these reverend fathers,
Yea, the *elect* of the land, who are assembled
To plead your cause. *Shakspeare. Henry VIII.*

The wisdom of nature is better than of books: prudence being a wise *election* of those things which never remain after one and the self-same manner. *Raleigh.*

The discovering of these colours cannot be done but out of a very universal knowledge of things: which so cleareth men's judgment and *election* as it is the less apt to slide into error. *Bacon.*

I will say positively and resolutely, that it is impossible an *elective* monarchy should be so free and absolute as an hereditary.

For what is man without a moving mind,
Which hath a judging wit, and chusing will?
Now if God's power should her *election* bind,
Her motions then would cease, and stand all still.
*Davies.*

I was sorry to hear with what partiality, and popular heat, *elections* were carried in many places. *King Charles.*

It could not but be a great comfort to Aaron, to see his rod thus miraculously flourishing; to see this wonderful testimony of God's favour and *election.* *Bp. Hall's Contemplations.*

Henry his son is chosen king, though young;
And Lewis of France, *elected* first, beguiled.
*Daniel.*

A vicious liver, believing that Christ died for none but the *elect*, shall have attempts made upon him to reform and amend his life. *Hammond.*

Some I have chosen of peculiar grace,
*Elect* above the rest; so is my will. *Milton.*

Him, not thy *election,*
But natural necessity, begot. *Id.*

F[illegible]m the new world her silver and her gold
C[illegible] like a tempest, to confound the old;
[illegible]g with these the bribed *electors'* hopes,
A[illegible]he gave us emperors and popes. *Waller.*

To [illegible]f compelling a man to be good, is a contradiction; for where there is force, there can be no choice: whereas all moral goodness consisteth in the *elective* act of the understanding will. *Grew's Cosmologia Sacra.*

They work not *electively*, or upon proposing to themselves an end of their operations. *Id.*

Thus while they speed their pace, the prince designs
The new *elected* seat, and draws the lines. *Dryden.*

The last change of their government, from *elective* to hereditary, has made it seem hitherto of less force, and unfitter for action abroad. *Temple.*

Thus to regulate candidates and *electors*, and new-model the ways of *election*, what is it but to cut up the government by the roots, and poison the very fountain of public security? *Locke.*

How or why that should have such an influence upon the spirits, as to drive them into those muscles *electively*, I am not subtle enough to discern. *Ray on the Creation.*

As charity is, nothing can more increase, the lustre and beauty than a prudent *election* of objects, and a fit application of it to them. *Sprat.*

You see in *elections* for members to sit in parliament, how far saluting rows of old women, drinking with clowns, and being upon a level with the lowest part of mankind, in that wherein they themselves are lowest, their diversions, will carry a candidate. *Steele.*

He h[illegible] a great and powerful king for his son-in-law[illegible]d can himself command, when he pleases, the whole [illegible]rength of an *electorate* in the empire. *Addison's Freeholder.*

Since the late dissolution of the club, many persons put up for the next *election.* *Id. Spectator.*

He calls upon the sinners to turn themsel[illegible]and live; he tells us that he has set before us life a[illegible]d death, and referred it to our own *election* which we will chuse. *Rogers.*

The conceit about absolute *election* to eter[illegible] life, some enthusiasts entertaining, hav[illegible] been made re[illegible] in the practice of virtue. *Atterbury.*

This prince, in gratitude to the people, by whose consent he was chosen, elected a hundred senators out of the commoners. *Swift.*

Lo! serve us on sudden,
In shape of porter, beef, and pudding,
Though like *electioneering* comes,
Strike up ye trumpets and ye drums! *Warton.*

Many an honest man, before as harmless as a tame rabbit, when loaded with a single *election* dinner, has become more dangerous than a charged culverin. *Goldsmith.*

Counties could neither be purchased nor intimidated. But their solemn determined *election* may be rejected; and the man they detest may be appointed by another choice, to represent them in parliament. *Junius.*

Man, thus endued with an *elective* voice,
Must be supplied with objects of his choice;
Where'er he turns, enjoyment and delight,
Or present, or in prospect, meet his sight. *Cowper.*

There are not, in this island, one million of persons who have a vote in *electing* parliament-men: and yet, in this island, there are eight millions of persons who must obey the law. *Beattie.*

The act of parliament settled the crown on the *electress* Sophia and her descendants. *Burke.*

Election, in British polity, is the choice of their representatives in parliament. See Parliament. In this consists the exercise of the democratical part of our constitution: for in a democracy there can be no exercise of sovereignty but by suffrage, which is the declaration of the people's will. In all democracies, therefore, it is of the utmost importance to regulate by whom and in what manner, the suffrages are to be given. And the Athenians were so justly jealous of this prerogative, that a stranger, who interfered in the assemblies of the people, was punished with death, being esteemed guilty of high treason, by usurping those rights of sovereignty to which he had no title. 'In Britain,' says Blackstone, 'where the people do not debate in a collective body, but by representation, the exercise of this sovereignty consists in the choice of representatives. The laws have therefore very strictly guarded against the usurpation or abuse of this power, by many salutary provisions; which may be reduced to these three points, 1. The qualifications of the electors. 2. The qualifications of the elected. 3. The proceedings at elections.

*As to the Qualification of Electors.*—The true reason of requiring any qualification, with regard to property, in voters, is to exclude such persons as are in so mean a situation, that they are esteemed to have no will of their own. If these persons had votes, they would be tempted to dispose of them under some undue influence or other. This would give a great, an artful or a wealthy man, a larger share in elections than is consistent with general liberty. If it were probable that every man would give his vote freely, and without influence of any kind; then, upon the true theory and genuine principles of liberty, every member of the community, however poor, should have a vote in electing those delegates to whose charge is committed the disposal of his property, his liberty, and his life. But since that can hardly be expected in persons of indigent fortunes, or such as are under the immediate dominion of others, all popular states have been obliged to establish certain qualifications; whereby some, who are suspected to have no will of their own, are excluded from voting, in order to set other individuals, whose will may be supposed independent, more thoroughly upon a level with each other. And this constitution of suffrages is framed upon a wiser principle, with us, than either of the methods of voting, by centuries or by tribes, among the Romans. In the method by centuries, instituted by Servius Tullius, it was principally property, and not numbers, that turned the scale; in the method by tribes, gradually introduced by the tribunes of the people, numbers only were regarded, and property entirely overlooked. Hence the laws passed by the former method had usually too great a tendency to aggrandise the patricians or rich nobles: and those by the latter had too much of a levelling principle. Our constitution steers between the two extremes. Only such are entirely excluded as can have no will of their own: there is hardly a free agent to be found, but what is entitled to a vote in some place or other in the kingdom. Nor is comparative wealth or property entirely disregarded in elections; for though the richest man has only one vote at one place, yet, if his property be at all diffused, he has probably a right to vote at more places than one, and therefore has many representatives. This is the spirit of our constitution: not that we assert it is in fact so perfect as we have endeavoured to describe it; for, if any alteration might be wished or suggested in the present form of parliaments, it should be in favor of a more complete representation of the people. But to return to the qualifications; and first, those of elections for knights of the shire. 1. By stat. 8 Hen. VI. c. 7 and 10, Hen. VI. c. 2. (amended by 14 Geo. III. c. 58), the knights of the shire shall be chosen of people, whereof every man shall have freehold to the value of forty shillings by the year within the county; which (by subsequent statutes) is to be clear of all charges and deductions, except parliamentary and parochial taxes. The knights of shires are the representatives of the landholders, or landed interests of the kingdom: their electors must therefore have estates in lands or tenements within the county represented. These estates must be freehold, that is, for term of life at least; because beneficial leases for long terms of years were not in use at the making of these statutes, and copyholders were then little better than villeins, absolutely dependent upon their lords. This freehold must be of forty shillings annual value; because that sum would then, with proper industry, furnish all the necessaries of life, and render the freeholder, if he pleased, an independent man; for bishop Fleetwood, in his Chronicon Pretiosum, written at the beginning of the eighteenth century, has fully proved forty shillings in the reign of Henry VI. to have been equal to £12 per annum in the reign of queen Anne; and, as the value of money is very considerably lowered since the bishop wrote, we may fairly conclude, from this and other circumstances, that what was equivalent to £12 in his days, is equivalent to £30 at present. The other

less important qualifications of the electors for counties in England and Wales, may be collected from the statutes 7 and 8 Will. III. c. 25; 10 Ann. c. 23; 2 Geo. II. c. 21; 18 Geo. II. c. 18; 31 Geo. II. c. 14; 3 Geo. III. c. 24, which direct, 2. That no person under twenty-one years of age, shall be capable of voting for any member. This extends to all sorts of members as well for boroughs as counties; as does also the next, viz. 3. That no person convicted of perjury, or subornation of perjury, shall be capable of voting in any election. 4. That no person shall vote in right of any freehold, granted to him fraudulently to qualify him to vote. Fraudulent grants are such as contain an agreement to recovery, or to defeat the estate granted; which agreements are made void, and the estate is absolutely vested in the person to whom it is so granted. And, to guard the better against such frauds, it is farther provided, 5. That every voter shall have been in the actual possession, or receipt of the profits, of his freehold to his own use for twelve calendar months before: except it came to him by descent, marriage, marriage-settlement, will, or promotion to a benefice or office. 6. That no person shall vote in respect of an annuity or rent-charge, unless registered with the clerk of the peace twelve calendar months before. 7. That in mortgaged or trust-estates, the person in possession, under the above-mentioned restrictions, shall have the vote. 8. That only one person shall be admitted to vote for any one house or tenement, to prevent the splitting of freeholds. 9. That no estate shall qualify a voter, unless the estate has been assessed to some land-tax and, at least twelve months before the election. 10. That no tenant by copy of court-roll shall be permitted to vote as a freeholder. Thus much for the electors in counties. As for the electors of citizens and burgesses, these are supposed to be the mercantile part or trading interest of this kingdom. But as trade is of a fluctuating nature, and seldom long fixed in a place, it was formerly left to the crown to summon pro re nata, the most flourishing towns to send representatives to parliament. So that as towns increased in trade, and grew populous, they were admitted to a share in the legislature. But the misfortune is, that the deserted boroughs continued to be summoned, as well as those to whom their trade and inhabitants were transferred; except a few which petitioned to be eased of the expense, then usual, of maintaining their member; four shillings a-day being allowed for a knight of the shire, and two shillings for a citizen or burgess; which was the rate or wages established in the reign of Edward III. Hence the members for boroughs now bear above a quadruple proportion to those for counties; and the number of parliament men is increased since Fortescue's time, in the reign of Henry VI., from 300 to upwards of 500, exclusive of those for Scotland. The universities were, in general, not empowered to send burgesses to parliament; though once, in 28 Edw. I. when a parliament was summoned to consider of the king's right to Scotland, there were issued writs, which required the university of Oxford to send up four or five, and that of Cambridge two or three, of their most discreet and learned lawyers for that purpose. But it was king James I. who indulged them with the permanent privilege to send constantly two of their own body to serve; for those students, who, though useful members of the community, were neither concerned in the landed nor the trading interest; and to protect in the legislature the rights of the republic of letters. The right of election in boroughs is various, depending entirely on the several charters, customs, and constitutions of the respective places, which has occasioned infinite disputes: though now, by statute 2 Geo. II. c. 24, the right of voting for the future shall be allowed according to the last determination of the house of commons concerning it; and, by statute 3, Geo. III. c. 15. no freeman of any city or borough (other than such as claim by birth, marriage, or servitude,) shall be entitled to vote therein, unless he has been admitted to his freedom twelve calendar months before. See BOROUGH.

2. *As to the Qualifications of Persons to be elected.*—Some of the qualifications to be elected members of the house of commons depend upon the la[illegible]and custom of parliaments, declared by the [illegible]e; others upon certain statutes. And from [illegible] it appears, 1. That they must not be aliens [illegible]n or minors. 2. That they must not be any of the twelve judges, because they sit in the lords' house; nor of the clergy, for they sit in the convocation; nor persons attainted of treason, or felony, for they are unfit to sit any where. 3. That sheriffs of counties, and mayors and bailiffs of boroughs, are not eligible in their respective jurisdictions, as being returning officers; but that sheriffs of one county are eligible to be knights of another. 4. That, in strictness, all members ought to have been inhabitants of the places for which they are chosen; but, this having been long disregarded, was at length entirely repealed by statute 14 Geo. III. c. 58. 5. That no persons concerned in the management of any duties or taxes created since 1692, except the commissioners of the treasury, nor any of the officers following (viz. commissioners of prizes, transports, sick and wounded, wine-licenses, navy, and victualling; secretaries, or receivers of prizes; comptrollers of the army accounts; agents for regiments; governors of plantations, and their deputies; officers of Minorca or Gibraltar; officers of the excise and customs; clerks or deputies in the several offices of the treasury, exchequer, navy, victualling, admiralty, pay of the army or navy, secretaries of state, salt, stamps, appeals, wine-licenses, hackney-coaches, hawkers, and pedlars,) nor any person that holds any new office under the crown, created from 1705, are capable of being elected, or sitting as members. 6. That no person having a pension under the crown during pleasure, or for any term of years, is capable of being elected or sitting. 7. That if any member accepts an office under the crown, except an officer in the army or navy accepting a new commission, his seat is void; but such member is capable of being re-elected. 8. That all knights of the shire shall be actual knights, or such notable squires and gentlemen as have estates

sufficient to be knights, and by no means of the degree of yeomen. This is reduced to a still greater certainty, by ordaining, 9. That every knight of a shire shall have a clear estate of freehold or copyhold to the value of £600 per annum, and every citizen and burgess to the value of £300, except the eldest sons of peers and of persons qualified to be knights of shires, and except the members for the two universities: which somewhat balances the ascendant which the boroughs have gained over the counties, by obliging the trading interest to make choice of landed men: and of this qualification the member must make oath, and give in the particulars in writing, at the time of his taking his seat. But, subject to these standing restrictions and disqualifications, every subject of the realm is eligible of common right: though there are instances, wherein persons in particular circumstances have forfeited that common right, and have been declared ineligible for that parliament, by a vote of the house of commons; or for ever, by an act of the legislature. But it was an unconstitutional prohibition, which was grounded on an ordinance of the house of lords, and inserted in the king's writs, for the parliament holden at Coventry, 6 Henry IV., that no apprentice or other man of the law should be elected knight for the shire therein; in return for which, our law books and historians have branded this parliament with the name of parliamentum indoctum, or the lack-learning parliament; and Sir Edward Coke observes, with some spleen, that there was never a good law made thereat.

With respect to the clergy, their right or capacity of sitting in parliament was for a long time contested; but at length, by 41 Geo. III. (U. K.) c. 63. it was enacted, that no person having been ordained to the office of priest or deacon, or being a minister of the Church of Scotland, shall be capable of being elected to serve in parliament as a member of the house of commons. The election of such persons is declared void; and if any person after his election is ordained, he must vacate his seat. The penalty for any person sitting as a member, contrary to this act, is £500 a-day: and proof of having celebrated divine service is declared prima facie evidence of the party's being ordained, &c.

3. *Respecting the method of proceeding.*—The third point regarding elections, is the method of proceeding therein. This is also regulated by the law of parliament, and by various statutes, all of which we shall blend together, and extract out of them a summary account of the method of proceeding to elections. As soon as the parliament is summoned, the lord chancellor, (or, if a vacancy happens during the sitting of parliament, the speaker, by order of the house, and without such order, if a vacancy happens by death in the time of a recess for upwards of twenty days,) sends his warrant to the clerk of the crown in chancery; who thereupon issues out writs to the sheriff of every county, for the election of all the members to serve for that county, and every city and borough therein. Within three days after the receipt of this writ, the sheriff is to send his precept, under his seal, to the proper returning officers of the cities and boroughs, commanding them to elect their members: and the said returning officers are to proceed to election within eight days from the receipt of the precept, giving four days notice of the same; and to return the persons chosen, together with the precept, to the sheriff. But elections of knights of the shire must be proceeded to by the sheriffs themselves in person, at the next county-court that shall happen after the delivery of the writ. The county-court is a court held every month or oftener by the sheriff, intended to try little causes not exceeding the value of 40s., in what part of the county he pleases to appoint for that purpose: but, for the election of knights of the shire, it must be held at the most usual place. If the county-court falls upon the day of delivering the writ, or within six days after, the sheriff may adjourn the court and election to some other convenient time, no longer than sixteen days, nor shorter than ten; but he cannot alter the place without the consent of all the candidates: and, in all such cases, ten days public notice must be given of the time and place of the election. And as it is essential to the very being of parliament that elections should be absolutely free, therefore all undue influences upon the electors are illegal, and strongly prohibited. As soon, therefore, as the time and place of election, either in counties or boroughs, are fixed, all soldiers quartered in the places are to remove, at least one day before the election, to the distance of two miles or more: and not to return till one day after the poll is ended. Riots likewise have been frequently determined to make an election void. By vote also of the house of commons, to whom alone belongs the power of determining contested elections, no lord of parliament, or lord-lieutenant of a county, has any right to interfere in the election of commoners; and, by statute, the lord warden of the cinque-ports shall not recommend any members there. If any officer of the excise, customs, stamps, or certain other branches of the revenue, presumes to intermeddle in elections, by persuading any voter or dissuading him, he forfeits £100, and is disabled to hold any office. Thus are the electors of one branch of the legislature secured from any undue influence from either of the other two, and from all external violence and compulsion. But the greatest danger is that in which themselves co-operate by the infamous practice of bribery and corruption. To prevent which it is enacted, that no candidate shall, after the date (usually called the teste) of the writs, or after the vacancy, give any money or entertainment to his electors, or promise to give any, either to particular persons, or to the place in general, in order to his being elected, on pain of being incapable to serve for that place in parliament. And if any money, gift, office, employment, or reward, be given or promised to be given, to any voter, at any time, in order to influence him to give or withhold his vote, as well he that takes as he that offers such bribe forfeits £500, and is for ever disabled from voting and holding any office in any corporation: unless, before conviction, he will discover some other offender of the

same kind, and then he is indemnified for his own offence. The first instance that occurs of election bribery, was so early as 13 Eliz., when one Thomas Longe acknowledged that he had given the returning officer and others of the borough for which he was chosen the sum of £4 to be returned member, and was for that premium elected. But for this offence the borough was amerced, the member was removed, and the officer fined and imprisoned. But as this practice has since taken much deeper and more universal root, it has occasioned the making of various statutes; to complete the efficacy of which, there is nothing wanting but resolution and integrity to put them in strict execution. Undue influence being thus guarded against, the election is to be proceeded to on the day appointed; the sheriff or other returning officer first taking an oath against bribery, and for the due execution of his office. The candidates likewise, if required, must swear to their qualification, and the electors in counties to theirs; and the electors both in counties and boroughs are also compellable to take the oath of abjuration, and that against bribery and corruption.

The principal British statutes on this subject are: 7 H. 4. c. 15: 8 H. 6. c. 7; 23 H. 6. c. 14; 2 W. & M. stat. 1. c. 7; 5 & 6 W. & M. c. 20; 7 W. III. c. 4; 7 & 8 W. III. cc. 7, 25; 10 & 11 W. III. c. 7; 12 & 13 W. III. c. 10; 6 Ann. c. 23; 9 Ann. c. 5; 10 Ann. cc. 19, 33; 2 Geo. II. c. 24; 8 Geo. II. c. 30; 18 Geo. II. c. 18; 19 Geo. II. c. 28; 10 Geo. III. c. 16; 11 Geo. III. c. 42; 28 Geo. III. c. 52.

The election being closed, the returning officer in boroughs returns his precept to the sheriff, with the persons elected by the majority: and the sheriff returns the whole, together with the writs for the county and the knights elected thereupon, to the clerk of the crown in chancery; before the day of meeting, if it be a new parliament, or within fourteen days after the election, if it be an occasional vacancy; and this under penalty of £500. If the sheriff does not return such knights only as are duly elected, he forfeits, by the old statutes of Henry VI., £100; and the returning officer in boroughs, for a like false return, £40; and they are besides liable to an action, in which double damages shall be recovered, by the later statues of king William; and any person bribing the returning officer shall also forfeit £300. But the members returned by him, are the sitting members, until the house of commons, upon petition, shall adjudge the return to be false and illegal. The form and manner of proceeding upon such petition are regulated by statute 10 Geo. III. c. 16. (amended by 11 Geo. III. c. 42, and made perpetual by 14 Geo. III. c. 15), which directs the method of choosing by lot a select committee of fifteen members, who are sworn well and truly to try the same, and a true judgment to give, according to the evidence. See PARLIAMENT.

Since the beginning of the reign of Henry VIII., the number of the representatives of the commons has been more than doubled. In his first parliament the house consisted only of 298 members; 360 have since been added by acts of parliament, or by the king's charter, either creating [illegible] or reviving old boroughs. Under the provisions of the acts 27 Hen. VIII. c. 26. sect. 29, and [illegible] & 35 Hen. VIII. c. 26. sect. 27., there were added twenty-four for Wales; twelve precisely by the first act for the counties, and twelve under the provision of the latter act for the boroughs. Two for the county, and two for the city of Chester, were added by stat. 34, 35, Hen. VIII. c. 13. Two for the county, and two for the city of Durham, by stat. 25 Car. II. c. 9. Forty-five for Scotland, by the acts of union with that kingdom; and 100 for Ireland, by the acts of union with that kingdom; and the remainder by charter.

The number of the house of commons may therefore be stated thus:—

| | Members. |
|---|---|
| In the first parliament of Hen. VIII. | 298 |
| Created since by positive statute | 168 |
| Created or restored by charter, &c.: viz.—By Hen. VIII. 16: by Edw. VI. 48: Mary, 21: Eliz. 60: Jac. I. 27: Car. I. 18: Car. II. 2 | 192 |
| Total | 658 |

Of these, there are elected, under the provisions of the reform act, of 1832,

| | |
|---|---|
| For England | 471 |
| — Ireland | 105 |
| — Scotland | 53 |
| — Wales | 29 |
| Total | 658 |

The number of places which send members, and the numbers of knights, citizens, burgesses, and barons, respectively sent by the several counties, cities, boroughs, and places throughout the united kingdom, will appear by the following statement:—

| | | Counties. | Members. | |
|---|---|---|---|---|
| 117 counties | England | 40 | 143 | Knights (in Scotland, also called commissioners) of shires. |
| | Ireland | 32 | 64 | |
| | Scotland | 33 | 30 | |
| | Wales | 12 | 15 | |
| | Total | 117 | 252 | |

Brought forward, Counties 117. Members 252.

| | | | | Citizens. | |
|---|---|---|---|---|---|
| 33 cities | England | 23 | 2 each | 46 | |
| | | 1 | 4 — | 4 | |
| | Ireland | 4 | 2 each | 8 | |
| | | 3 | 1 each | 3 | |
| | Scotland | 2 | 2 | 4 | |
| | | | | — | 65 |

| | | | | Burgesses | |
|---|---|---|---|---|---|
| 210 boroughs, large towns, and districts | England | 160 | | 274 | |
| | Ireland | 26 | | 28 | |
| | Scotland | 19 | | 19 | |
| | Wales | 14 | | 14 | |
| 3 universities | England | 2 | 2 each | 4 | |
| | Ireland | 1 | 2 | 2 | |
| — | | | | —— | 341 |
| 372 places choose | | | | | 658 members. |

The most important changes effected by the reform bill consist in the disfranchisement of fifty-six boroughs, in Cornwall and elsewhere, whose constituency was insignificant, and the transfer of the elective franchise to [illegible], large and populous manufacturing towns. By this arrangement, Manchester, Birmingham, Leeds, Sheffield, Sunderland, Devonport, Wolverhampton, Bolton, Bradford, Blackburn, Halifax, Macclesfield, Oldham, Stockport, Stoke-upon-Trent, Stroud, and Brighton return two members each to parliament; and the following places, Ashton, Bury, Chatham, Cheltenham, Dudley, Frome, Gateshead, Huddersfield, Kidderminster, Kendal, Rochdale, Salford, South Shields, Tynemouth, Wakefield, Walsall, Warrington, Whitby, Whitehaven, and Merthyr-Tydvil, are privileged to elect one member each. The districts of Lambeth, Marylebone, Finsbury, and the Tower Hamlets were erected into boroughs, returning two members each; and five members are added to the Irish representation, viz. one additional to the following places, the Dublin university, Belfast, Galway, Limerick, and Waterford; the boundaries of boroughs and districts are extended, and new places admitted as contributary both in Wales and Scotland.

Election of Ecclesiastical Persons. Elections for the dignities of the church ought to be free, according to the stat. 9 Ed. II. cap. 14. If any persons that have a voice in elections, take any reward for an election in any church, college, school, &c., the election shall be void. And if any persons of such societies resign their places to others for reward, they incur a forfeiture of double the sum; and both the parties are rendered incapable of the place. Stat. 31 Eliz. c. 6.

Election of Scottish Peers. See Peers.

Election of Verderors of the Forest (electionæ viridariorum forestæ), in law, a writ that lies for the choice of a verderor, where any of the verderors of the forest are dead, or removed from their offices. This writ is directed to the sheriff, and the verderor is to be elected by his freeholders of the county, in the same manner as coroners. *New. Nat. Brev.* 366.

Elector (in Germ. churfüst, kurfüst, or wahlfürst) was even in recent times a title of several princes of the German empire of considerable power and dignity. 'During a long period,' says Dr. Robertson (Hist. Charles V.), 'all the members of the Germanic body had a right to assemble, and to make choice of the person whom they appointed to be their head. But, amidst the violence and anarchy which prevailed for several centuries in the empire, seven princes who possessed the most extensive territories, and who had obtained an hereditary title to the great offices of the state, acquired the exclusive privilege of nominating the emperor. This right was confirmed to them by the golden bull of Charles IV.; the mode of exercising it was ascertained, and they were dignified with the appellation of electors. The nobility and free cities being thus stripped of a privilege which they had once enjoyed, were less connected with a prince towards whose elevation they had not contributed by their suffrages, and came to be more apprehensive of his authority. The electors, by their extensive power, and the distinguishing privileges which they possessed, became formidable to the emperors, with whom they were placed almost on a level in several acts of jurisdiction. Thus the introduction of the electoral college into the empire, and the authority which it acquired, instead of diminishing, contributed to strengthen, the principles of hostility and discord in the Germanic constitution.'

The seven princes above alluded to were the three ecclesiastical princes, the archbishop of Cologne, Mentz, and Treves; and the four secular, the count Palatine, the king of Bohemia, the marquis of Brandenburgh, and the duke of Saxony.

In 1648 the duke of Bavaria took the place of the count Palatine, who was outlawed by the emperor for having accepted the crown of Bohemia; but he was at length restored to his rank, and a new electoral dignity was created for the former, which increased the number of electors to eight. In 1692 a ninth electorate was added by the emperor Leopold, in favour of the duke of Hanover, of the house of Brunswick Luneburg. From that period, to the year 1777, the electors

ollege consisted of the three ecclesiastical electors, Mentz, Treves, and Cologne, and the six secular, Bohemia, the palatinate of the Rhine, Saxony, Brandenburg, Bavaria, and Hanover. The dominions of the last elector palatine of the Rhine, having devolved in December 1777 to the elector of Bavaria, the electoral college was again reduced to eight members, until the peace of Luneville; when the three ecclesiastical electorates were secularised, the archbishop of Ratisbon introduced as a new elector arch-chancellor, and the duke of Wirtemberg, the landgrave of Hesse Cassel, the margrave of Baden, and the grand duke of Tuscany, as duke of Saltzburg, raised to the electoral dignity. This increased the number of electors to ten, viz. the elector arch-chancellor, Bohemia, Bavaria, Saxony, Brandenburg, Hanover, Wirtemberg, Hesse Cassel, Baden, and Saltzburg.

This arrangement was finally destroyed, as we have seen (article DIET), in the year 1806, when the German empire was dissolved. Bavaria and Wirtemberg, on joining the Confederation of the Rhine, under the protection of the French empire, assumed the royal dignity; Hanover was in possession of the French; Baden and Saltzburg took the titles of grand dukes; the elector arch-chancellor that of the prince primate of the Confederacy of the Rhine: and the year following Saxony assumed the royal dignity; Hesse Cassel was annexed to the new kingdom of Westphalia; Bohemia as part of the dominions of Austria, and Brandenburg as part of those of Prussia, reverted to these two houses as independent monarchical states. And thus the title of elector, which for so long a series of years conferred a rank equal to that of the old kings of Europe, became finally extinct.

The last electors of the German empire were, 1. Charles Theodore, baron Dahlberg, elector of Ratisbon, and arch chancellor, now prince primate. 2. Frederick William III., king of Prussia, elector of Brandenburg. 3. George III., king of Great Britain, elector of Hanover. 4. Ferdinand Joseph, elector of Saltzburg, now duke of Saltzburg. 5. Frederick II., elector, now king of Wirtemberg. 6. Charles Frederick, elector, now grand duke of Baden. 7. William X., elector of Hesse Cassel, driven from his dominions by the French. 8. Maximilian Joseph, elector, at present king of Bavaria. 9. Frederick Augustus IV., elector, at present king of Saxony; and, 10. Francis II., elector of Bohemia, afterwards emperor of Austria.

The electors besides the power of electing an emperor, had a right to capitulate with the new head of the empire, to dictate the conditions on which he was to reign and to depose him if he broke those conditions. They actually deposed Adolphus of Nassau, in 1298, and Wenceslaus in 1401. They were sovereign and independent princes in their respective dominions, had the 'privilegium de non appellando illimitatum,' that of making war, coining, and exercising every act of sovereignty. They formed a separate college in the diet of the empire, and had among themselves a particular covenant, or league, called the 'Kur verein.' They had precedence of all the other princes of the empire, even of cardinals, and ranked with kings. There was, however, a difference between the secular and ecclesiastical electors; none of the latter could be chosen emperor, and they were to be thirty years of age before they could attain the electoral dignity, whilst the majority of the secular ele[illegible]rs was fixed at eighteen years of age, and an[illegible] them might be placed at the head of the [illegible]e; indeed they might even vote in their ow[illegible]r. The functions of the electors were exercised by deputies. The elector of Mentz was arch-chancellor in Germany; Treves, in Gaul and the kingdom of Arles; Cologne, in Italy; Bohemia was arch-cupbearer; Bavaria, arch-sewer, or officer who serves out the feasts; Saxony, arch-marshal; Brandenburg, arch-chamberlain; Hanover, arch-treasurer. During the vacancy of the imperial throne, the elector of Saxony used to be vicar of the empire in the north, and the elector of Bavaria of the southern circles. On the demise of an emperor of Germany, or a vacancy ensuing in the imperial throne, the electors were summoned by the archbishop of Mentz to meet (generally at Frankfort) within three months. One month was ordinarily allowed for their determination; if it was delayed longer they were, according to the imperial constitution, to be fed on bread and water until they had made a choice. Both their dress and functions are particularly described by Du Cange.

ELE'CTRICAL,
ELECTRI'CIAN, *n. s.*
ELECTRI'CITY,
ELE'CTRIFY, *v. a.*
ELE'CTRISE, *v. a.*
ELECTRO'METER, *n. s.*

Gr. ηλεκτρον; Latin, *electrum*, amber, which, having the quality when warmed by friction of attracting bodies, gave to one species of attraction the name of electricity, and to the bodies that so attract the epithet electric; which also means produced by an electric body; and metaphorically, rapid; powerful. Bacon uses electre for a metallic compound. An electrician is he who is skilled in electricity. To electrify, *electrum* and *fio*, to render electric, or apply electricity, and to electrise, are used synonymously. Electrometer, an instrument for ascertaining the presence and portion of electricity in any given body.

Change silver plate or vessel into the compound stuff, being a kind of silver *electre*, and turn the rest into coin. *Bacon.*

If that attraction were not rather *electrical* than magnetical, it was wondrous what Helmont delivereth concerning a glass, wherein the magistery of loadstone was prepared, which retained an attractive quality. *Browne.*

By *electrick* bodies do I conceive not such only as take up light bodies, in which number the ancients only placed jet and amber; but such as, conveniently placed, attract all bodies palpable. *Id.*

An *electrick* body can by friction emit an exhalation so subtile, and yet so potent, as by its emission to cause no sensible diminution of the weight of the *elec-*

*trick* body, and to be expanded through a sphere, whose diameter is above two feet, and yet to be able to carry up lead, copper, or leaf gold, at the distance of above a foot from the *electrick* body. *Newton.*

When I would observe the *electricity* of the atmosphere with this instrument, I thrust the pin I into the cork D, and holding the rod by its lower end A, project it out of a window on the upper part of a house, into the air; raising the end of the rod with the *electrometer*, so as to make an angle of about fifty or sixty degrees with the horizon. *Cavallo.*

Then mark how two *electric* streams conspire
To form the resinous and vitreous fire. *Darwin.*

If a metallic point be fixed on the prime conductor, and the flame of a candle be presented to it, on *electrising* the conductor either with vitreous or resinous ether, the flame of the candle is blown from the point, which must be owing to the *electric* fluid in its passage from the point carrying along with it a stream of atmospheric air. *Id.*

But now a bride and mother—and now there!
How many ties did that stern moment tear!
From thy Sire's to his humblest subject's breast
Is linked the *electrick* chain of that despair,
Whose shock was as an earthquake's, and opprest
Thy land which loved thee so that none could love
thee best. *Byron.*
And the wild sparkle of his eye see[illegible] caught
From high, and lightened with *electri*[illegible]aght.
*Id.*

1. The particular branch of science denominated electricity appears to have derived its name from that of the first substance in which any of its properties were discovered. This was amber, the Greek name of which is ἠλεκτρον, evidently derived from Ἠλεκτωρ, a name by which Homer designates the Sun. It has been said by some that the ancients, observing amber to possess the property of attracting light substances when rubbed, termed it electrum, and that hence arose the word electricity. Those who entertain this opinion, would derive the name from the Greek verb ἑλκω to draw; but this appears to us to be a very forced derivation, since amber was doubtless called by the name of electron, long before it was known to possess the magnetic property of attraction. Perhaps it was so called from its bright and shining appearance. But, whatever may be the etymology of the term, it is now employed to designate that science which investigates the attractions and repulsions, the emissions of light, and explosions, which are produced, not only by the friction of vitreous, resinous, and metallic surfaces, but by the heating, cooling, evaporation, and mutual contact of a vast number of substances.

2. It is rather remarkable that, although the attractive energy of electricity has all the appearance of being a very recent discovery, it has been said to be 'the first physical fact recorded in the history of science.' The electrical properties of amber were known and pointed out upwards of 2000 years ago; but the subject did not engage the attention of the learned till the beginning of the seventeenth century. This was perhaps a fortunate circumstance, since it at all events prevented the science from being clouded or perverted by the ignorance of early times.

3. Dr. William Gilbert, of Colchester, appears to have been the first person who essentially contributed to the establishment of electricity as a science. In the year 1600 he published his work entitled De Magnete, which contains a number of experiments made with various substances, possessing the properties of amber, now termed electrics. Of Dr. Gilbert, Cavallo says that he ought to be considered as the father of electricity.

4. No further discoveries were made in this science of any importance till the year 1670, when the celebrated Mr. Boyle much enlarged the list of electrics, and by experiment discovered that their effects were much increased by warming and wiping them before the application of friction, and that during the friction they emitted faint flashes of light; this appearance he considered as an additional characteristic of the electrical power.

5. Otto Guericke of Magdeburg, the inventor of the air-pump, and a contemporary with Mr. Boyle, confirmed the experiments of the latter, and much enlarged the state of electrical knowledge. He constructed an apparatus in which the electric, a globe of sulphur, was made to revolve on an axis; the hand was applied to it as a rubber; and by this contrivance, which was in principle the same as the most modern construction of the electrical machine, he was enabled to obtain an accumulation of electricity far beyond any thing that had been effected by his predecessors. This philosopher discovered also the principle of electrical repulsion.

6. In the year 1709 appeared the first treatise on electricity; it was the production of Mr. Hawksbee, who far exceeded his predecessors in the discoveries which he made. He was the first who observed the electric power of rubbed glass; the flashing light of an excited electric had been observed by Boyle; but, as Mr. Hawksbee by his glass globe could collect the electric matter in much greater quantities than had been done before, he had the pleasure of beholding the intensity of its light, and of observing the snapping noise by which its discharges are attended. Some of the experiments made by Mr. Hawksbee were very curious, and deserve more notice than has hitherto been taken of them. Among others the following may be mentioned. He lined more than one-half of a glass globe with sealing-wax, and, having exhausted it of its air, he put it in motion in an appropriate frame. On applying his hand to it, for the purpose of excitation, he was surprised to observe an exact image of his hand on the concave surface of the wax, as distinctly defined as if there had been nothing but transparent glass between his eye and his hand, although the wax was in some places an eighth of an inch in thickness. When pitch was used instead of wax the effect was the same.

7. After this period the science of electricity appears to have been for some time stationary, from the discoveries of Sir Isaac Newton absorbing the attention of the public; but, soon after the death of that distinguished individual, it obtained renewed attention, and some very important discoveries were made in it by Mr.

.ephen Grey, a pensioner of the Charter-house. Vith the date of this gentleman's experiments ommenced the modern triumph of electricity. Directing his attention to the nature of electrical henomena, he endeavoured to excite them in ll known bodies; and, though in many cases he vas unsuccessful, he thus added considerably to he catalogue of electrics. Many substances, in vhich no attractive power was excited by rubing while in their natural state, became strongly ttractive if excited after being moderately varmed, but lost this property as they became old. This fact, says the late ingenious Mr. inger, clearly pointed out a relation between ie state of bodies and their power of evincing lectric appearances; and the nature of this reition was explained by Mr. Grey's subsequent xperiments. Every attempt to render metals lectric by friction or otherwise proved inefectual in the hands of Mr. Grey, as well as in iose of his predecessors, when it occurred to im that, as electric light appeared to pass beveen excited bodies and such as were incapable f excitation, the attractive power might be also apable of communication from one to the ther.

8. For this purpose Mr. Grey inserted a wire nd ball, by means of a piece of cork, in the xtremity of a glass tube, and, on rubbing the ibe, found its attractive power was communiated to the wire and ball. He proceeded with iis experiment until the length of the wires vhich he used became inconvenient. He then uspended the ball by means of pack-thread, from ie tube, and found the electricity was still comiunicated. The same result was obtained when ie ball was suspended by the pack-thread, from balcony twenty-six feet high: on exciting the ibe small light substances were attracted by the all from the pavement of the court below.

9. In connexion with Mr. Wheeler, Mr. Grey fterwards extended his experiments, and suceeded in transmitting the electric power from is excited tube through nearly 800 feet of packhread, without any apparent diminution of its force. In arranging the apparatus for these experiments these gentlemen found that a silken cord was incapable of transmitting the attractive power of the tube; an effect which they at first attributed to its comparative smallness, but they afterwards observed that a wire of much smaller diameter carried off the electrical effect completely, and thus discovered that there are in nature various bodies differently qualified for the transmission of the electric matter, some conveying it most readily, and to a great distance, and others incapable of transmitting it to any perceptible distance. The former class of bodies are now termed conductors of electricity, and the second class non-conductors, or electrics; these terms are said to have been first applied to them by Desaguliers.

10. Soon after Mr. Grey's discovery of the difference between conductors and non-conductors, M. Du Fay discovered the difference between positive and negative, or, as they were for some time, and are still by some called, the vitreous and resinous electricities. This discovery was accidentally made in consequence of his observing, that a piece of leaf-gold, repelled by an excited glass tube, and which he endeavoured to drive about the room with a piece of excited gum copal, instead of being repelled by it, as it was by the glass tube, was eagerly attracted. The same was the case with sealing wax, sulphur, resin, and many other substances. He discovered, also, that it was impossible to excite a tube in which the air was condensed. He also observed, that such substances as were least susceptible of electric excitement by friction were the best conductors of electricity; though all the bodies he tried became electric by communication when placed on a non-conducting support. In this way he electrified himself, being supported by silk lines, and touched by an excited glass tube; and on this occasion the abbe Nollet, who accompanied him in these experiments, drew the first electrical spark from the human body.

11. M. Du Fay, says Mr. Singer, has also the merit of having given the first clear account of that apparent repulsion which obtains in most electric experiments, and which was first observed by Otto Guericke, who had noticed that the fibres of an electrified feather receded from each other and from the tube or globe by which they h[illegible] n electrified. Du Fay viewed this as the [illegible]on of a general principle in electricity, wh[illegible] nay be thus expressed. Electrified bodies attract all those that are not so, but repel them as soon as they are electrified by their contact.

12. The consideration of this general principle led the same assiduous philosopher to a discovery f the first importance, viz. the existence of two distinct attractive powers, produced by the friction of different substances, the one excited by rubbing glass, rock crystal, gems, wool, hair, and many other substances, he called vitreous electricity. The other, resulting from the friction of amber, copal, gum-lac, resins, sealing-wax, &c., he named resinous electricity. The characteristics of these attractive powers are, that they strongly attract each other, and produce a mutual counteraction of effect, whilst they separately act in an apparently similar manner on all unelectrified bodies: but the effect of either of them is destroyed or weakened by the approach of the other. If gold leaf be electrified by rubbed glass it immediately recedes from it, and will not again approach whilst it remains in its electric state. But in this state it is strongly attracted by any excited body of the resinous class, and will fly to sealing-wax or amber more rapidly than to an unelectrified body. Hence it was concluded, by Du Fay, that there are two distinct electricities, each repulsive of its own particles, but having a strong attraction for those of the other. So that all bodies electrified with the vitreous electricity repel those that are similarly electrified, and attract such as are unelectrified or endowed with the resinous electricity. And the converse of this is the case with such as are possessed of the resinous electricity.

12.* The terms resinous and vitreous electricity, continues the same author, were sufficiently appropriate at the time they were proposed; but it has been since found that either kind of elec-

tricity can be obtained at pleasure, both from glass and sealing-wax, by varying the nature of the substance with which they are rubbed. Hence the vitreous electricity of Du Fay is now called positive electricity; and the resinous, negative electricity; terms first proposed by Dr. Franklin.

13. To the labors of Messrs. Grey and Wheeler, and their coadjutors Du Fay and Nollet, all subsequent electricians are highly indebted; their means of research were extended by the improvement of electrical apparatus, necessarily resulting from the discovery of conducting and non-conducting power; whilst the generalisation of electric phenomena by Du Fay, and his discovery of the distinction between positive and negative electricity, was an enlargement of the existing sphere of knowledge in a degree before unparalleled. From this period, indeed, the science assumed a more important aspect, its cultivators increased in number, and the communication of their researches constituted a prominent feature in the transactions of the most celebrated societies and academies of Europe.

14. It was in the year 1745 that the remarkable properties of the Leyden phial were first observed. This discovery was merely accidental; yet it tended, more than any other discovery hitherto made, to promote the progress of electricity. The circumstances that led to this discovery were the following:—Professor Muschenbroeck observed, that when conducting bodies were placed on glass, &c., and electrified, their electricity was very soon carried off by the conducting particles floating in the atmosphere; he therefore imagined, if a conducting substance were put into a glass phial, that it could be charged much higher than in open air, as the glass would protect it from the dissipating action of the atmosphere.

15. This idea he attempted to put in practice by filling a small phial with water, which is a conducting substance. For this purpose he passed the end of a wire through the cork of the phial, so as to touch the water, and then charged the water by bringing the wire in contact with the prime conductor, but found no extraordinary result from the experiment. Mr. Cuneus, of Leyden, who was one of the party when the professor made the experiment, repeated it afterwards; and, happening to hold the phial in his hand, after he had connected the wire with the prime conductor, until the water, as he supposed, had received a full charge of electricity, and then applying his other hand to unloose the wire from the conductor, he received such a sudden shock in his arms and breast, as filled him with astonishment.

16. The report of such a strong effect of the electric power immediately raised the attention of all the philosophers in Europe. Many of them greatly exaggerated their accounts; either from a natural timidity, or a love of the marvellous. M. Muschenbroeck, who tried the experiment with a very thin glass bowl, told M. Reaumur in a letter written soon after the experiment, that he felt himself struck in his arms, shoulder, and breast, so that he lost his breath; and was two days before he recovered from the effects of the blow, and the terror. He added, that he would not take a second shock for the whole kingdom of France. Mr. Allamand, who made the experiment with a common beer glass, said, that he lost his breath for some moments; and then felt such an intense pain all along his right arm, that he was apprehensive of bad consequences, but it soon after went off without any inconvenience, &c. Other philosophers, on the contrary, showed their magnanimity, by receiving a number of electric shocks as strong as they could possibly make them. Mr. Boze wished that he might die by the electric shock, in order to furnish, by his death, an article for the memoirs of the Academy of Sciences at Paris. But, adds Dr. Priestley, in his history of electricity, it is not given to every electrician to die in so glorious a manner, as the justly envied Richman. Public curiosity was promptly and highly excited by this discovery, and all Europe was presently filled with itinerant exhibitors of the Leyden Jar, who obtained a livelihood by administering the electrical shock. The experiment was repeated and varied by the electricians of every country, and an explanation of the principle on which the effect depends, was offered by Dr. Franklin of America, and Dr. Watson in England, at the same time, without the one knowing that the other was engaged in the pursuit. The propositions of these two philosophers, observes Mr. Singer, were nearly similar; but that of Dr. Franklin being the more perfect, and having a real priority of publication, was adopted, and has been since celebrated as the Franklinean Theory of Electricity. He referred all electrical effects to the motion of a peculiar fluid, repulsive of its own particles, and having an attraction for all other matter. And he considered the opposite electricities of glass and sealing-wax as indications of different states of this fluid: the vitreous electricity being the plus or positive state, and the resinous the minus or negative state. All bodies can contain a certain quantity of electric fluid in a latent state. If this quantity be increased they become electrified positively; if it be diminished they are rendered negative. The production of electrical effects is therefore nothing but the result of the unequal distribution, by art, of a naturally diffused fluid. Such are the leading principles of the Franklinean theory; they have been considered mathematically by Mr. Cavendish, by Æpinus, and others, and, with some modifications, apply to most of the electrical phenomena at present known.

17. Frequent experiments, attended with close observation, were likely enough to lead to important results in this interesting science; and we have now arrived at a period in its history which is perhaps the most distinguished of any. We allude to the discovery of the identity of electricity and lightning. Mr. Grey and Dr. Wall seem to have been the first who thought of the resemblance between thunder and the snapping noise which is heard when an excited electric is approached by a conducting substance. The abbé Nollet, Mr. Winckler, and others, also enumerated many resemblances between the phenomena of electricity and those of thunder;

but they did not think of any method by which their suppositions could be brought to the test of experiment. The remarks of the abbé Nollet on this subject, considering the time at which they were made, are so striking, that we consider them well deserving of a place in the memory of every lover of the electrical science, and shall here record them.

18. 'If,' says he, 'any one should take upon him to prove from a well connected comparison of phenomena, that thunder is in the hands of nature what electricity is in ours; that the wonders which we now exhibit at our pleasure, are little imitations of those great effects that frighten us, and that the whole depends upon the same mechanism: if it can be demonstrated that a cloud prepared by the action of the winds, by heat, by a mixture of exhalations, &c., is opposite to a terrestrial object; that this is the electrified body, and at a certain proximity to that which is not; I avow that this idea, if it were well supported, would give me a great deal of pleasure; and, in support of it, how many specious reasons present themselves to a man who is well acquainted with electricity! The universality of the electric matter, the readiness of its action, its inflammability, and its activity in giving fire to other bodies, its property of striking externally and internally even to their smallest parts, the remarkable example we have of this effect in the Leyden experiment, the idea which we might truly adopt in supposing a greater degree of electric power, &c.; all these points of analogy, which I have been some time meditating, begin to make me believe, that, by taking electricity for the model, one might form to one's self, in respect to thunder and lightning, more perfect and more probable ideas than have hitherto been offered.'

19. It is generally admitted that the French philosophers were the first to verify these conjectures: they preceded the justly celebrated Dr. Franklin in drawing the electric matter from the clouds by means of an iron conducting rod; but, within a month after they had done so, the American philosopher effected the same thing in a manner that never seems to have entered into their minds. Speaking of the observations of the abbé Nollet, above quoted, Mr. Singer justly remarks, that thy bear no comparison with the acute conception, sound philosophical argument, and satisfactory experiments, by which Dr. Franklin has demonstrated the identity of the electric fluid, and the cause of thunder. Dr. Franklin, says he, had observed with equal attention the peculiarities of the natural phenomenon, and the power to which he ascribed its production; he enumerated the following as their leading features of resemblance.—

(1.) The zigzag form of lightning corresponds exactly in appearance with an electric spark that passes through a considerable interval of air.

(2.) Lightning most frequently strikes such objects as are high and prominent, in preference to others, as the summits of hills, the masts of ships, high trees, towers, spires, &c. The electric fluid, when striking from one body to another, always passes through the most prominent parts.

(3.) Lightning is observed to strike most frequently into those substances that are good conductors of electricity, such as metals, water, and moist substances; and to avoid those that are non-conductors.

(4.) Lightnings inflame combustible bodies. The same is effected by electricity.

(5.) Metals are melted by a powerful charge of electricity. This phenomenon is one of the most common effects of a stroke of lightning.

(6.) The same may be observed of the fracture of brittle bodies, and of other expansive effects common to both causes.

(7.) Lightning has often been known to strike people blind. Dr. Franklin found, that the same effect is produced on animals when they are subject to a strong electric charge.

(8.) Lightning destroys animal life. Dr. Franklin killed turkies of about ten pounds weight, by a powerful electric shock.

(9.) The magnetic needle is affected in the same manner by lightning and by electricity, and iron may be rendered magnetic by both causes. The phenomena are therefore strictly analogous, and differ only in degree; but if an electrified gun-barrel will give a spark, and produce a [illegible]d report at two inches distance, what effect [illegible] not be expected from perhaps 10,000 acres [illegible]trified cloud? And is not the different e[illegible] of these conductors, equal to the different [illegible]mit of their effects? But to ascertain the accuracy of these ideas, let us have recourse to experiment.

Pointed bodies receive and transmit electricity with facility; let, therefore, a pointed metal rod be elevated in the atmosphere, and insulated; if lightning is caused by the electricity of the clouds, such an insulated rod will be electrified whenever a cloud passes over it, and this electricity may then be compared with that obtained in our experiments. Such were the suggestions of this admirable philosopher: they soon excited the attention of the electricians of Europe, and having attracted the notice of the king of France, the approbation he expressed excited in several members of the French Academy a desire to perform the experiment proposed by Franklin, and several insulated and pointed metallic rods were erected for that purpose.

20. In this pursuit the most active persons were two French gentlemen, Messrs. D'Alibard and Delar. The former prepared his apparatus at Marly la Ville, five or six leagues from Paris; the latter at his own house, on some of the highest ground in that capital. M. D'Alibard's machine consisted of an iron rod forty feet long, the lower extremity of which was brought into a sentry-box, where the rain could not come; while on the outside it was fastened to three wooden posts by long silken strings defended from the rain. This machine was the first that was favored with a visit of the etherial fire. M. D'Alibard himself was not at home; but, in his absence, he had entrusted the care of his apparatus to one Coissier, a joiner, who had served fourteen years in the army, and on whose courage and understanding he could depend. This artisan had all the necessary instructions given him; and was desired to call some of his

neighbours, particularly the curate of the parish, whenever there should be any appearance of a thunder storm. At length the long expected event arrived. On Wednesday, 10th May, 1752, between two and three P. M. Coissier heard a pretty loud clap of thunder. Immediately he ran to the machine, taking with him a phial furnished with a brass wire; and presenting the wire to the end of the rod, a small spark issued from it with a snap like that which attends a spark from an electrified conductor. Stronger sparks were afterwards drawn in the presence of the curate and a number of other people. The curate's account of them was, that they were of a blue color, an inch and a half in length, and smelled strongly of sulphur. In making them, he received a stroke on his arm a little below the elbow; but he could not tell whether it came from the brass wire inserted into the phial, or from the bar. He did not attend to it at the time; but the pain continuing, he uncovered his arm when he went home in the presence of Coissier. A mark was perceived round it, such as might have been made by a blow with the wire on his naked skin.

21. Dr. Franklin himself had an opportunity, about a month after this, of verifying his own hypothesis. He was waiting for the erection of a spire in Philadelphia, not imagining that a pointed rod of a moderate height could answer the purpose. At last it occurred to him, that by means of a common kite he could have a readier access to the higher regions of the atmosphere than any other way whatever. Preparing, therefore, a large silk handkerchief and two cross sticks of a proper length on which to extend it, he took the opportunity of the first approaching thunder-storm to take a walk into a field where there was a shed convenient for his purpose. But, dreading the ridicule which too commonly attends unsuccessful attempts in science, he communicated his intention to nobody but his son, who assisted him in raising the kite. A considerable time elapsed before there was any appearance of success. One very promising cloud had passed over the kite without any effect; when, just as he was beginning to despair, he observed some loose threads of the hempen string to stand erect and avoid one another, just as if they had been suspended by the conductor of a common electrical machine. On this he presented his knuckle to a key which was fastened to the string, and thus obtained a very evident electric spark. Others succeeded even before the string was wet; but, when the rain had begun to descend, he collected electric fire pretty copiously. He had afterwards an insulated iron rod to draw the lightning into his house; and performed almost every experiment with real lightning, that had before been done with the artificial representations of it by electrical machines. With this apparatus he connected two small bells and a pendulum between them, which were so arranged as to ring when electrified, and thus to give notice of the approach of a thunder-cloud.

22. Experiments with the electrical kite were repeated in all directions, and with various success; in France a most brilliant display of its powers was made by M. de Romas. He constructed a kite of seven feet in height, and three feet wide; this kite he raised to the height of 550 feet by a string, in which was interwoven a fine metallic wire to render it a good conductor. On the 7th of June, 1753, when this kite was elevated, M. de Romas informs us that he drew from the conductor to which the string was attached sparks three inches long, and a quarter of an inch thick. On one or two occasions he met with increasing success, and was enabled to draw sparks, or rather streams, of the electric matter from his apparatus, of a foot in length, and an inch in thickness. But on the 16th of August, 1757, M. de Romas, with an additional length of string to his kite, was still more successful. The storm at the time was not great, neither was there much thunder, and but little rain had fallen; yet streams of lightning, nine or ten feet long, and an inch in thickness, darted from his conductor to the ground, accompanied with a noise equal to that attending the discharge of a pistol.

23. It was not to be expected that, in the infancy of the science, experiments on such a scale should be always conducted with safety: accidents will happen in the management of the best constructed apparatus, and the first operators on atmospherical electricity received many severe and unexpected shocks. Numerous, however, and dangerous as these accidents have been, there is only one instance known of their having proved fatal; to that we have already alluded, and shall here state some of the leading particulars attending the melancholy catastrophe. Professor Richman, of St. Petersburgh, had constructed an apparatus for making experiments on atmospherical electricity, for a work on that subject in which he was engaged. On the morning of the day that terminated his mortal career he was attending a meeting of the Academy of Sciences, and, hearing the sound of distant thunder, he hastened home to observe his apparatus, and took with him Mr. Solokow, his engraver, that he might make any sketch required during the action of the apparatus. On inspecting his electrometer, he found it indicated 4° on the quadrant; and, while pointing out to his friend the danger to be apprehended should it rise to 45°, a loud peal of thunder burst over the city. At this moment the professor inclined his head towards the apparatus to observe the height to which the electrometer had risen, and while in this posture, with his hand about a foot from the conducting rod, a ball of fire, of a bluish-white color, flashed from the rod to his head, with a report equal to that of a pistol. Richman fell backwards on a chest behind him, and expired in a moment. Solokow was much stunned by the discharge; and described the ball of electric fire as being about the size of his closed hand. The wires of the apparatus were melted and scattered about the room; the door was torn from its hinges and thrown upon the floor; the house was filled with sulphureous vapor, the ashes were thrown from the fire-place, and the door-posts rent asunder.

24. A vein was opened in the professor's body twice, but no blood followed; after which, they

endeavoured to recover life by violent friction, but in vain. There appeared a red spot on the forehead, from which spirted some drops of blood through the pores, without wounding the skin. The shoe belonging to the left foot was burst open, and uncovering the foot at that part, they found a blue mark; whence it was concluded, that the electric matter having entered at the head, made its way out again at that foot. Upon the body, particularly on the left side, were several red and blue spots resembling leather shrunk by being burnt. Many more also became visible over the whole body, and particularly over the back. That upon the forehead changed to a brownish red, but the hair of the head was not singed. In the place where the shoe was burst, the stocking was entire; as was the coat every where, the waistcoat only being singed on the fore flap: but there appeared on the back of Mr. Solokow's coat long narrow streaks, which probably arose from fragments of the red hot wires falling on it and burning off the nap. Next day, when the body was opened, the cranium was very entire, having neither fissure nor contra-fissure: the brain was sound; but the transparent pellicles of the wind-pipe were excessively tender, and easily rent. There was some extravasated blood in it, as also in the cavities below the lungs. Those of the breast were quite sound; but those towards the back of a brownish black color, and filled with more of the blood above-mentioned. The throat, the glands, and the small intestines, were all inflamed. The singed leather-colored spots penetrated the skin only. In forty-eight hours the body was so much corrupted that they could with difficulty place it in the coffin. It is said that, at the time of his death, professor Richman had in his pocket seventy rubles of silver, which were not in the least affected by the lightning.

25. There was no longer any doubt remaining as to the identity of lightning, and the electricity produced by the electrical machine; and the great practical use made of this discocovery was to secure buildings, ships, &c., from being damaged by lightning, by erecting on them pointed metallic rods, rising a little above the highest part of the building, and passing along it so as to communicate with the ground or the nearest water, a full account of which will be given in the course of this essay.

26. A short time previous to the event of professor Richman's death, a most remarkable attempt was made by a gentleman in Italy, to gain on the credulity of his countrymen and others, by pretending that if odoriferous substances were enclosed in glass tubes, and the tubes excited, the medicinal virtues of those substances would transpire through the glass, impregnate the atmosphere of the conductor, and thus be readily communicated to the patient without being taken into the stomach. The most astonishing cures were said to have been performed by these medicated tubes; and the inventor, J. Francisco Pivati, published an account of them to the world. Both the British and French philosophers united in investigating the merits of Pivati's experiments, and the result was a complete failure, in every instance in which the experiments were repeated, though this was done in the presence of those who pretended to have been so successful; and, in some cases, with the very apparatus they themselves had used. The theory was, consequently, no longer credited.

27. To enumerate, in chronological order, all the discoveries that have been made in the science of electricity, from the invention of the Leyden phial to the present period, would swell this introductory sketch far beyond its proper limits; and yet, as having so eminently contributed towards raising the science to its present elegant, improved, and highly prosperous state, there are several whose names it would be injustice to pass by in silence. As the chief of these we may notice the following: Mr. Canton, an eminent English electrician, who distinguished himself by a very successful repetition of Dr. Franklin's experiments on atmospherical electricity; a method of electrifying the air of a room, either positively or negatively; and particularly by disproving the correctness of the theory of vitreous and resinous electricity, and showing that every electric is capable of giving it both in a positive and negative form, according to the nature of the surface of the body, and the kind of rubber with which it is excited.

This ingenious electrician made several remarkable experiments on electrical atmospheres, which led to the establishment of the fact, that bodies immersed in them became possessed of the electricity the opposite of that of the body into the atmosphere of which they are placed.

28. In connexion with the name of Canton must be mentioned that of Beccaria, author of a work entitled Dell' Elettricismo Artificiale e Naturale, and which was translated into English in the year 1776. The discoveries of Signor Beccaria were nearly the same as those of his contemporary, Mr. Canton, although they had had no communication with each other on the subject. Beccaria also made some very important experiments on the conducting power of water; in these he ascertained, that water is a very imperfect conductor of electricity; that it conducts it according to its quantity, and that, when used in very small quantities, its resistance was greatest. See Beccaria.

29. Some interesting discoveries were made in the year 1759, on the electrical qualities of silk, by Mr. Symner. An account of these he published in the Philosophical Transactions. His attention seems to have been directed to the subject by accidentally observing, that, on pulling off his silk stockings in the evening, a crackling noise proceeded from them, and that in the dark they emitted sparks of fire. He found that these electrical appearances were always the strongest when a silk and worsted stocking were both on one leg, and that it was of no consequence which of them was next the skin, but that they must be of different colors, one white and the other black. Two stockings of this description, worn on the leg for the short space of ten minutes, on being pulled off, stood inflated as if the leg had been within them, and, on being drawn asunder, attracted each other at

the distance of eighteen inches. These effects are always most powerful when the stockings are new, or when newly washed. Those who choose to try this very simple experiment will find it succeed equally well if the stockings are placed one within the other, drawn a few times through the hand, and then quickly pulled asunder.

30. Mr. Kinnersly, an intimate friend of Dr. Franklin, made several experiments that contributed to the advancement of electricity. These related chiefly to the discovery of the two electricities, the conducting power of water at different temperatures, and the power of strong charges of electricity when passed through brass wires. In the first of these experiments he had been anticipated by M. Du Fay; but he soon perceived that Du Fay did not consider the two electricities in the same light as that in which they were viewed by Franklin, viz. positive and negative.

31. In 1757 a work appeared on electricity, entitled Disputatio Physica Experimentalis de Electricitatibus, by Mr. Wilke, of Rostock, in Lower Saxony, in which the author gives some very interesting details of his researches respecting the electricity developed during the melting and cooling of electrical substances; and also that produced by the friction of different bodies. This gentleman found that, when sulphur is melted in an earthen vessel placed on non-conductors of electricity, it is strongly electrified when taken out after it is cold; but that it shows no signs of electricity if cooled upon electrics. Melted sealing-wax, he found, acquired negative electricity when poured into glass vessels, but positive electricity when poured into sulphur. Mr. Wilke also confirmed the experiments of Dr. Franklin and Mr. Canton on electrical atmospheres, and illustrated the phenomena of electrical light.

32. M. Alpinus, a member of the Imperial Academy at St. Petersburgh, seems to have been the first who gave to the world a mathematical demonstration of the theory of electricity. An exposition of his treatise was published by the abbé Hauy; and an excellent paper, on the same subject, was drawn up for the Royal Society by Mr. Cavendish, before he knew any thing of the theory of M. Alpinus. The merits of M. Alpinus are certainly great, but we consider Cavendish as having much higher claims as an electrician; his experiments on the conducting power of water and wire; his very ingenious construction of the artificial torpedo; and above all, his success in employing electricity as a chemical agent, justify this opinion.

33. The labors of Dr. Priestley, as an electrician, are deservedly held in the highest esteem; the doctor brought no common share of ingenuity and perseverance to bear upon the science; and to him we are indebted for a considerable number of important improvements and interesting experiments in electricity, as connected with chemistry; for a most excellent treatise on the History of Electricity; an Introduction to Electricity; several valuable papers on the same subject, inserted in the Philosophical Transactions; and for numerous improvements in the construction of electrical apparatus.

34. The theories of Alpinus and Cavendish were much improved on by the ingenuity of M. Coulomb. By those philosophers the action of the electric matter, in producing attraction or repulsion, was considered merely as diminishing with the distance; but by the experiments of Coulomb it was proved that the electrical force, like that of gravity, is in the inverse ratio of the squares of the distance. The instrument with which Coulomb made his experiments was of his own construction: he gave it the name of the 'torsion balance,' from the manner of its action; a description of it will be given in the course of this essay. Coulomb also made numerous experiments for the purpose of ascertaining the laws by which the dissipation of the electrical matter in the air is regulated; and also to ascertain the distribution of it in an overcharged body. In prosecuting these enquiries he was certainly as successful as could possibly be expected, considering the extreme delicacy of his apparatus, and the effects which the variableness of the atmosphere produces on the strongest electrical experiments.

35. To M. De Saussure we are also indebted for some remarkably fine experiments, which seem to have been made with great care, on the electricity developed during the conversion of fluids into vapor. The fluids on which he operated were distilled water, spirit of wine, and ether. The same philosopher likewise made some highly interesting experiments on atmospherical electricity, for the verification of which he made a journey to the Alps.

36. Most of those who have devoted their attention to the study of electricity, as a science, have distinguished themselves by the invention of some new instrument, the use of which has generally led to some important discovery.

This was peculiarly the case with Sig. Volta, professor of natural philosophy at Como in Italy. He invented the electrophorus, an ingeniously constructed instrument for collecting and retaining the electric matter; and another called a condenser, the use of which is to accumulate, and render visible, the smallest portions of electricity, natural or artificial. The celebrity of Volta, however, rests chiefly on the important improvements which he made in that branch of electricity designated GALVANISM, under which they will be fully considered.

37. We have already noticed the scientific experiments of Coulomb, and must here observe that Dr. Robison, late professor of natural philosophy in the university of Edinburgh, is justly entitled to a share of the honor bestowed on Coulomb, since he had, so early as the year 1769, made numerous and remarkably successful attempts, with an admirable electrometer of his own invention, to determine the laws of electric action. But the professor did not publish an account of his experiments at the time they were made, which certainly gives them the appearance of posteriority. The conclusion to which Dr. Robison's experiments led him was, that the force of electrical attraction and repulsion is nearly in the inverse ratio of the square of the distance. 'The specific result,' says Dr. Brewster, 'which he obtained was, that the mutual repulsion of

two spheres, electrified in the same manner, varied as $\frac{1}{d^{2}.06}$, $d$ representing the distance of their centres'

38. As electricity now began to be more generally cultivated, it was to be expected that great improvements in the construction of apparatus would take place. This was the case; and the brilliant success of Van Marum of Haarlem, in experiments which had failed in the hands of others, was obviously owing to the prodigious power of the large apparatus constructed by Mr. Cuthbertson of London, and placed in Tyler's museum at Haarlem. Some notice of these experiments will be taken in the course of this article; at present it may be sufficient to state, that, whatever other philosophical instrument makers may have conceived, Mr. Cuthbertson has brought forth the most useful, because the most powerful, electrical apparatus with which we are yet acquainted.

39. Mr. Cavallo is justly entitled to respectful notice in every historical sketch of the rise and progress of the electrical science, to which he made many important additions. This philosopher made numerous experiments on atmospherical electricity; and also added to our stock of electrical apparatus, by his invention of the most ingeniously constructed instruments for measuring, doubling, condensing, and multiplying electricity.

40. There are other philosophers who have liberally contributed to the progressive improvement of this branch of natural [illegible] on whose merits we cannot here dwell; [illegible] this we the less regret as their im[illegible] and discoveries must be still fresh in [illegible] of those who feel an interest in the [illegible] Among these we would simply enumera[illegible] genious and laborious Nicholson, the [illegible] M. Hauy, Mr. Brooks, Mr. Bennet, M[illegible] Mr. Morgan, La Place, and the truly [illegible] annalist M. Poisson.

40.* Many other names of deserved [illegible] might be here mentioned, as having [illegible] labored in raising electricity to its [illegible] nent station among the sciences; b[illegible] bring this part of our article to a co[illegible] acknowledging our obligations to th[illegible] mating that we shall occasionally a[illegible] of their labors. This remark is mea[illegible] particularly to the excellent treatise on [illegible] by the late Mr. George John Singer, a [illegible] lecturer on this science. Mr. Singer's [illegible] stands high in the scientific world; and [illegible] petent judges have pronounced his Elemen[illegible] Electricity and Electro-Chemistry one of the best and most original works on the subject in the English language.

## PART I.

### ON THE PHENOMENA OF EXCITED ELECTRICITY.

41. The more simple methods of exciting electrics enable us to perform several pleasing and instructive experiments without the aid of costly and complex apparatus; the principal of these we now proceed to describe.

If two silk ribands, the one black and the other white, about two or three feet in length, and perfectly dry, be applied to each other by their surfaces, and then drawn smartly a few times between the finger and thumb, or over dry silk velvet or woollen cloth, they will be found to adhere to each other with considerable force; and when separated at one end will rush together again with rapidity. Each riband, when separated, will attract any light substances to which it is presented; and, if the experiment be made in a dark room, a flash of light will occasionally attend the separation of the ribands.

42. Sticks of sealing-wax, resin, or sulphur, when rubbed with dry woollen cloth, or fur; and tubes or rods of glass, when rubbed with silk, exhibit similar powers; and, if of sufficient size, produce, when applied within a short distance of the face or hand, a distinct and singular sensation. These effects having been first produced by the friction of amber (electron) are called electrical phenomena; and the processes employed for their production, the excitation of electricity.

43. Attraction is the phenomenon most constantly attendant on excitation; it is therefore considered as an indication of the presence and action of electricity, and is the basis of all its tests. Electricians formerly, says Mr. Singer, employed for such trials a light wooden or metal needle, supported by its centre on a point, or a thread or feather delicately suspended. To these the excited body was presented, and, if they were attracted by it, the attraction was attributed to electricity, and the excited body was called an electric.

44. This suspended needle, and every other contrivance for the same purpose, they called an electroscope, when employed to indicate the existence of electricity; and an electrometer when considered as a measure of its force; but the latter term appears fully sufficient, since every contrivance hitherto employed to ascertain the presence of electrical phenomena is also calcu[illegible] measure their power. The most useful [illegible] for common purposes, are con[illegible] [illegible]pending two narrow sli[illegible] [illegible] of a glass cylind[illegible] [illegible]d they will [illegible] [illegible]ence [illegible] [illegible] cause [illegible] [illegible] the cylinder. [illegible] from the [illegible] threads [illegible] [illegible] for the [illegible] strips. [illegible] [illegible], but they are more [illegible] [illegible], suspended by threads or [illegible] without a glass [illegible] and other electrometers will [illegible]r.

45. [illegible] are [illegible] characterised by the [illegible] of light substances; the consequent [illegible] of motion in them, and of sensation [illegible] by the evolution or produ[illegible]. There are various methods by wh[illegible] may be produced, but the following [illegible] most obvious sources of their production. (1.) Friction. (2.) Change of form. (3.) Change of temperature. (4.) Contact of dissimilar bodies.

46. Of the first kind, viz. friction, the instances are most numerous, and, as Mr. Singer remarks, under certain limitations, universal; they may indeed be obtained by rubbing any of an extensive list of resinous and silicious substances; and of dry, vegetable, animal, and mineral productions. The electricity thus excited, is most readily rendered visible by its effects on the gold leaf electrometer.

47. Examples of the second kind are also very numerous. If a small quantity of sulphur be melted and poured into a conical wine glass, it will contract a little, and become electrical in cooling. A silk thread with a small hook at the end of it, or a rod of glass should be inserted in the sulphur while in a fluid state, to serve as a handle for separating it from the glass when cold. On being separated from the glass, the sulphur will exhibit other signs of electricity; if kept in the glass it will retain its electric virtue for years, and evince it very perceptibly on every attempt to separate the two substances.

48. Mr. Henly discovered that chocolate, fresh from the mill, becomes strongly electrical, as it cools in the tin pans. It soon loses this property, but recovers it once or twice, by being melted in an iron ladle and poured into the tin pans. When the mass becomes dry, the electricity cannot be restored by melting, unless olive oil be mixed with it in the ladle; in which case it completely recovers its electric power. M. Chaptal observed the same circumstance during the congelation of glacial phosphoric acid. Calomel also, when it fixes by sublimation to the upper part of a glass vessel, has been found strongly electrical. The condensation of vapor, and the evaporation of fluids, though apparently opposite processes, are alike sources of electrical excitation.

49. Various crystallised gems, and a stone called the Tourmalin, become electrical by the mere application of heat; but no other substances have yet unequivocally manifested the same property; though the effects of friction are generally increased, if it is preceded by a moderate elevation of temperature.

50. The contact of dissimilar bodies is probably in all cases the real primary cause of electrical excitement, but it is rarely employed alone, for electricity is known to us only by its effects, which are constantly the result of an artificial arrangement, and consequently may not immediately succeed the primary cause of electric powers, similar in their separate action on the electrometer, and other indifferent matter; but exerting a mutual influence on each other, destructive of their individual properties.

51. It was at first supposed that these phenomena were peculiar to the substances by which they were produced; hence the power excited by the friction of glass was termed vitreous electricity; and that by the friction of sealing-wax, resinous electricity. It has, however, long since been proved that both powers are produced in every case of electrical excitation; and, because their mutual counteraction of effect resembles that of an affirmative and negative power, they have been styled positive and negative electricity.

52. The determination of these two states of electricity in different excited bodies, continues Mr. Singer, is of importance to the practical electrician, and may be thus effected:—Sealing-wax when rubbed on woollen cloth is negatively electrified. Glass, when rubbed with silk is positively electrified. Let an electrometer be made to diverge by its being approached by an excited stick of sealing-wax: while in this state, approach it with any excited body, the electricity of which is to be determined. If the divergence of the electrometer increase, the presented body is negative; if it be diminished, the presented body is positive. In other words, all those substances that lessen the divergence occasioned by excited wax, are positive; and such as increase it, negative: whilst those which lessen the divergence produced by excited glass, are negative; and such as increase it positive. Examining, by this test, the effects produced in some of the instances of excitation already considered, we find the truth of the preceding statements, and the relation of the different electrical states to the processes by which they are produced, become more intelligible. Care ought to be taken to destroy the divergence of the electrometer after every experiment of this nature; this is best effected by touching its cap with one end of a piece of brass wire.

53. As an illustration of the doctrine here advanced let the following simple and easily performed experiments be made.

(1.) Roll up a warm and dry piece of flannel, so that it may be held by one extremity, while a stick of sealing-wax is rubbed with the other. After a slight friction present the flannel to an electrometer, which will instantly diverge; while this divergence continues, bring the stick of sealing-wax near the cap, and the leaves of the electrometer will quickly collapse. Both these substances, it is obvious, are electrified by mutual friction, but their electricities are opposite; that of the wax being negative, and that of the flannel positive.

(2.) The electricities thus produced are equal to each other: for if the friction be repeated, and the two substances be both presented to the electrometer at the same time, no signs of electricity appear: the opposite electricities, when applied together, producing a reciprocal counteraction of effect.

(3.) If a black and a white silk riband be excited in contact, in the manner already described, the black riband will be found to be negatively, and the white one positively electrified.

(4.) Take the sulphur cone described at 47, apply it and the glass separately to the electrometer; the cone will be found to be negatively and the glass positively electrified.

54. From the above experiments it appears, that in all cases of excitation positive and negative electricity are produced at the same time, and may be observed by the use of proper means. But it also appears that by friction with the same substance, different bodies are variously affected; for glass rubbed with silk evinces positive electricity: but wax rubbed with silk is rendered negative. Again, polished glass, when rubbed with silk, skin-wool, or metal, becomes positive; but if it be excited by friction against the back of a living cat, it appears negative. Wool, silk,

or fur, rubbed against sealing-wax, are rendered positive; but gold, silver, or tin, are by the same process rendered negative.

55. Electricians have drawn up tables for showing at one view what kind of electricity will be produced by rubbing various electrics with different substances; the following Mr. Singer gives us on the authority of Mr. Cavallo.

| | Is rendered | By friction with |
|---|---|---|
| The back of a cat | Positive | Every substance with which it has been hitherto tried. |
| Smooth Glass | Positive | Every substance hitherto tried, except the back of a cat. |
| Rough Glass | Positive | Dry oiled silk, sulphur, metals. |
| | Negative | Woollen cloth, quills, wood, paper, sealing-wax, white-wax, the human hand. |
| Tourmalin | Positive | Amber, blast of air from bellows. |
| | Negative | Diamonds, the human hand. |
| Hare's skin | Positive | Metals, silk, loadstone, leather, hand, paper, baked wood. |
| | Negative | Other finer furs. |
| White silk | Positive | Black silk, metals, black cloth. |
| | Negative | Paper, hand, hair, weasel's skin. |
| Black silk | Positive | Sealing-wax. |
| | Negative | Hare's, weasel's, and ferret's skin, loadstone, brass, silver, iron, hand, white silk. |
| Sealing | Positive | Some metals. |
| | Negative | Hare's, weasel's, and ferret's skin, hand, leather, woollen-cloth, paper, some metals. |
| Baked wood | Positive | Silk. |
| | Negative | Flannel. |

In a note appended to the preceding table Mr. Singer says, Mr. Cavallo had inserted metals, which appeared to imply that the friction of all metals electrified sealing-wax positively; this I find is not the case: iron, steel, plumbago, lead, and bismuth, render sealing-wax negative, and all the other metals I have tried leave it positive. I have therefore made a slight alteration in the table. The least difference in the conditions of such experiments will occasion singular varieties of result: with the same rubber (an iron chain), positive electricity may be excited in one stick of sealing-wax, and negative in another, if the former have its surface scratched, and the latter be perfectly smooth. Many repetitions of each experiment are therefore essential to an accurate conclusion.

56. The result of experiments of the kind just described, Mr. Singer found to be much influenced by the state of the bodies employed, and the manner in which the friction was applied to them. In general, he remarks, strong electric signs can only be produced by the friction of dissimilar bodies; but similar substances, when rubbed together so that the motion they individually experience is unequal, are sometimes electrified; and, in such cases, the substance of which the friction is limited to the least extent of surface, is usually negative. This he farther remarks is the case with the strings of a violin, over a limited part of which the bow passes in its whole length, and the hairs of the bow become positive.

57. From these facts he draws the following conclusions, viz. that positive and negative electricity are concomitant phenomena, and that in all cases of electrical excitement, they are both produced, though one only may occasionally appear; and that these phenomena are not peculiar to any distinct class of bodies, but may be produced alternately in various substances, by changing the materials or method by which friction is communicated to them.

MUNICATION OF ELECTRICITY.

Cavallo, speaking of communicated remarks, that under such a title falls at we know of the subject: the irtue, says he, from one body hat causes its light; by being communicated to other bodies we see its attraction; by its quick transition it melts metals, destroys animal and vegetable life; and, in short, it is by this communication that the science is known and cultivated.

The following observations and experiments on this particular part of the subject we give from Mr. Singer, with a few necessary exceptions, preferring them to any thing we have yet seen for their appropriateness and conciseness.

59. From the few simple experiments which we have already described the reader must be aware that electricity can be communicated or conveyed from one body to another. But the faculty of electrical transmission is very different in different bodies; some convey it with great rapidity; others more slowly; and there are some that appear absolutely to arrest its progress. Examples of this fact are apparent in the most simple experiments. The divergence of an electrified electrometer may be destroyed, weakened, or maintained, by touching its cap with different bodies; now, as the divergence of the electrometer is caused by its electricity, such effects can only be produced by the relative power of the touching bodies to deprive it thereof; for so long as the electricity remains the divergence will continue unaltered.

60. This may be shown most satisfactorily by the two following experiments. (1.) Touch the cap of the electrified electrometer with a stick of dry glass, sulphur, or sealing-wax; the divergence of its leaves will continue; this shows therefore that these substances do not transmit electricity. (2.) Touch the cap of the electrified electrometer with a piece of wood, a rod of

any metal, a green leaf, or with the point of the finger; its divergence immediately ceases. Such bodies therefore permit the transmission of electricity.

61. By experiments of this kind it is found, that there is a gradation of effect from one class of bodies to the other. Those which transmit electricity with facility are called conductors; those whose transmitting powers are inferior, imperfect conductors; and such as have no power of transmission, non-conductors: but in general the various bodies in nature are divided into two classes only; the remote extremes of each forming the intermediate class.

62. In the following enumeration of the principal conductors, and non-conductors, the substances are placed nearly in the order of their perfection; but the determination of this circumstance has not hitherto been accomplished with much precision.

CONDUCTORS.

All the known metals.
Well-burnt charcoal.
Plumbago.
Concentrated acids.
Powdered charcoal.
Diluted acids, and saline fluids.
Metallic ores.
Animal fluids.
Sea water.
Spring water.
River water.
Ice above 13° of Fahrenheit.
Snow.
Living vegetables.
Living animals.
Flame.
Smoke.
Steam.
Most saline substances.
Rarefied air.
Vapor of alcohol.
Vapor of ether.
Most of the earths.
Most stones.

To the above Dr. Brewster adds powdered glass and powdered sulphur, which, he says, have been found to be conductors by the experiments of Van Swinden.

63. Many of the above mentioned substances fail to conduct electricity when they are made perfectly dry; hence it is concluded that their conducting power arises from the water they contain. Indeed this faculty does not permanently exist in any of the bodies enumerated, but varies and disappears with their modifications of temperature, &c. Thus hot water is a much better conductor than cold water is; the same is the case with charcoal and other substances.

NON-CONDUCTORS.

64. These are also denominated electrics, as before remarked, and occasionally insulators; but the latter term will only apply to the most perfect of them.

Shell-lac, amber, resins.
Sulphur, wax, jet.
Glass and all vitrifications talc
The diamond and all transparent gems.
Raw silk, bleached silk, dyed silk.
Wool, hair, feathers.
Dry paper, parchment, and leather.
Air, and all dry gases.
Baked wood, dry vegetable substances.
Porcelain, dry marble.
Some silicious and argillaceous stones.
Camphor, elastic gum, lycopodium.
Native carbonate of barytes.
Dry chalk, lime, phosphorus.
Ice at 13° of Fahrenheit.
Many transparent crystals when perfectly dry.
Ashes of animal bodies.
Ashes of vegetable bodies.
Oils, the heaviest are the best.
Dry metallic oxides.

65. The most perfect non-conductors, continues Mr. Singer, become conductors by the accession of moisture; hence the necessity of preserving them clean and dry during electrical experiments. Resinous substances, raw silk, and Muscovy talc, are least liable to attract moisture, and are therefore most useful where perfect non-conductors are required.

66. Glass becomes moist on its surface only, and this moisture may be checked by covering it with sealing-wax or good varnish. Glass consequently enters most extensively into the structure of an electrical apparatus; its strength, and the facility with which it may be procured of any form, fitting it most admirably for that purpose.

67. Many substances in the preceding list lose their non-conducting power, and become conductors, when intensely heated. Such is the case with red hot glass, melted resin, wax, &c.; but the most intensely heated air, if unaccompanied by flame, is not a conductor. Many fibrous substances attract water so readily, that it is absolutely necessary to dry and warm them before their non-conducting property appears; this is particularly the case with paper, flannel, parchment, leather, &c. The influence of heat on this property is, indeed, very remarkable. It is well exemplified in the following instance: Wood, in its natural state, is a conductor; if baked, its moisture is expelled, but its organisation is not altered: it is then a non-conductor. By exposure to a greater heat its volatile elements are dissipated, and its indestructible base (charcoal replete with alkali) only remains; this is a conductor; but if exposed again to heat, with access of air, it suffers combustion, and is converted into ashes and gases, which are non-conductors.

68. There does not appear any definite relation between the chemical characters of bodies and their conducting powers; for the best conductors (metals), and the best non-conductors (resins, sulphur, &c.), are alike inflammable substances. The products of combustion, too, are dissimilar in this respect: acids and alkalis conduct electricity, but the metallic oxides do not. Neither does it appear that specific gravity, hardness, tenacity, or crystalline arrangement of particles, are connected with the power of electrical transmision; for similar characters of this kind are possessed by bodies of both classes. Thus platina, the densest of bodies, is

a conductor; but so also are charcoal, and rarefied air.

69. Whatever be the cause of non-conducting power, it is evident that without its existence as a property of air, and other substances, electrical phenomena would be unknown; for, if the faculty of electrical transmission existed universally, the cause of every effect of this kind would be dissipated and lost at the moment of its production. But, by the property of non-conductors, any excited electricity which they surround is preserved; and it is then said to be insulated. A support of glass, sealing-wax, silk, or any non-conductor, is, for the same reason, called an insulating support, or an insulator; and a piece of metal or other conductor, so supported, is named an insulated conductor.

70. The use of insulators and conductors in practical electricity may be exemplified by very simple experiments, which, says Mr. Singer, will form no improper introduction to the consideration of more important apparatus. He gives the following:—

(1.) Hold a sheet of writing paper before a fire till it be perfectly dry and warm; lay it flat upon a table and rub the upper surface briskly with Indian rubber. The paper will adhere to the table, and if lifted up by one corner and presented quickly to any flat conducting surface, as the wainscot, &c., will be attracted by and adhere to it. This adherence is occasioned by the attraction of electricity excited on the paper, which in its dry state is an insulator or non-conductor; the necessity of which circumstance to the success of the experiment is rendered evident by the paper falling down as soon as it has attracted moisture enough to destroy its insulating property, and is further apparent from the impossibility of producing the same results by the friction of paper in its ordinary state of dryness.

(2.) Repeat the excitation of the paper in a dark room; when the paper is lifted from the table by its corner, present the knuckle of the other hand successively to various parts of its surface, a series of faint divergent flashes of light will ensue. This light is occasioned by the transmission of the electricity excited on the paper to the hand; and it occurs at every contact, because the non-conducting power of the paper prevents its transmission from one part of the surface to another, the effect existing over the whole portion that has been subjected to friction.

(3.) Excite the dry sheet of paper as before, and place it upon an insulating stand, a piece of apparatus to be described hereafter, present the knuckle to the edge or under side of the metal plate, and a bright spark will appear; but a second approach will produce either a very slight effect, or none that is perceptible; for the metal is a conductor, and it transmits the whole effect of the excited electric at once. Hence insulated conductors are employed in the electrical apparatus to receive or collect the diffused electricity of excited bodies, and to apply it to the purposes of experiment.

71. It is rather remarkable that the ingenuity of Mr. Singer did not lead him to try the experiments here detailed with brown, as well as writing paper. This idea, however, does not seem to have occurred to writers on the subject till very recently. When very coarse brown paper is used, the effects produced are much stronger; nor is there in this case any necessity for the application of Indian rubber; for if a piece of coarse brown paper, of about twelve inches long and six inches broad, be made very dry and warm, and then drawn gently three or four times between the knee and the lower part of the arm, both being covered with woollen, it will be found to be highly electrical, and will with considerable force adhere to the wainscotting of a room. If any conducting substance be applied to it immediately after the friction, such as the knuckle of the folded hand, or a brass ball, a strong spark will instantly dart from the paper to it, attended by the usual snapping sound. So powerful indeed is excited brown paper, when carefully managed, that a small jar may be charged with it; and it has been recently proposed as a covering for a circular board to be used instead of a plate of glass in constructing a cheap kind of electrical machine.

## PART II.

### ELECTRICAL APPARATUS.

[illegible]ous, extremely beautiful, and de-[illegible]ments may be made in electricity with but a small quantity of apparatus, and that of a simple form, and at a trifling expense. Such an apparatus consists chiefly of a few glass tubes, of about an inch in diameter and two or three feet long; one or two very large sticks of sealing-wax; a few pieces of silk, old silk handkerchiefs answer extremely well; a few pieces of new flannel; some wires and balls of different sizes; and half a dozen small balls made of the pith of elder.

But, when it is required to exhibit the more striking and important of the electrical phenomena, we must have recourse to a much more powerful, complicated, and consequently expensive apparatus.

73. The principal article, the very fountain, so to speak, of all electrical apparatus, is what is commonly denominated the electrical machine; of the structure of this instrument we have various accounts in different works on electricity, but as it is not our intention to swell our pages with a repetition of what others have said before us on what is now become obsolete, we shall not put our readers to the trouble of travelling over an uninteresting description of apparatus which has nothing to recommend it but its antiquity.

74. Of the *Electrical Machine*, there are now various kinds in use; these, however, may be classed under two heads, the cylindrical and the plate machine. But before entering on a particular description of these we feel strongly inclined to lay before our readers the following remarks of Mr. Singer on electrical apparatus in general.

75. The structure of an electrical apparatus, says this distinguished electrician, consists in the judicious arrangement of insulators and conductors, so that the former shall prevent the dissipa-

tion of the effects the latter are employed to collect or transmit; thus the cap and leaves of the gold leaf electrometer form a conductor intended as a test of electrical action; but to fit this conductor for its purpose it is insulated, being supported on the glass cylinder by which the leaves are enclosed.

76. When electricity is excited by friction, the quantity of effect is, within certain limits, proportioned to the extent of the rubbed surface; hence it appears that every part of that surface is concerned in the production of the general effect. Now, that this may be the case, it is essential that every part of such surface be insulating; for friction is a progressive process, a succession of contacts; and the effect produced by it in the first instant would otherwise be destroyed by conducting power, before a second operation could contribute to its increase. For this reason electricity is most usually excited by the friction of a conductor of limited size, against the extensive surface of a non-conductor.

77. An apparatus, then, properly arranged for the excitation of electricity, is called an electrical machine. To excite positive electricity, a glass tube, of about an inch in diameter and two feet long, is generally used; the excitation is produced by rubbing it lengthwise by a piece of dry oiled silk, held in the hand which is made to grasp the tube. In this way both the silk and the tube are electrified; but the electricity of the silk is destroyed by the conducting power of the hand, and that of the tube only appears. In a similar way negative electricity is procured by rubbing a large stick of sealing-wax with dry flannel or fur; the electrical power of the sealing-wax being all that results.

78. Thus, with the most simple machinery, two processes are employed to procure the opposite electricities, although they are at the same time both excited in each; but, to obtain them both, it would be necessary to insulate the silk, or flannel, used as rubbers, either by employing them in a very dry state, rolled up, so as to produce the friction with one extremity, at a distance from the hand, or by affixing them to a glass or other non-conducting support; but neither of these methods would be convenient where many experiments are to be made. This difficulty does not occur when large surfaces of glass are employed instead of tubes as sources of excitation; for these may be made circular, and proper friction be communicated to them from a fixed cushion, placed on an elastic support, against which they are made to revolve.

79. We shall here give a brief description of the two forms of the electrical machine which are most generally approved of, and shall begin with the cylindrical machine. In point of power, the very best kind of cylindrical electrical machine with which we are acquainted is the improved one, as constructed by the late Mr. Geo. Adams, of London, an eminent lecturer, and author of several valuable philosophical works. This machine is represented in plate I, fig. 1, ELECTRICITY. The parts of the machine, which fall more immediately under our attention are, (1.) The electric, or the glass cylinder which is to be excited. (2.) The mechanical contrivances by which it is put in motion. (3.) The cushion and its appendages. (4.) The conductor or conductors. The glass cylinder of the machine is put in motion by a simple winch. This is less liable to be out of order than those that are turned with a multiplying wheel, and also enables us to excite the machine more powerfully. The cylinder, FGHI, is supported by two strong perpendicular pieces, DE. The axis of one cap of the cylinder moves in a small hole at the upper part of one of the supports. The opposite axis passes through the upper part of the other support. To this axis the winch or handle is fitted. The cushion is supported and insulated by a glass pillar; the lower part of this pillar is fitted into a wooden socket, to which a regulating screw is adapted, to increase or diminish the pressure of the cushion against the cylinder. A piece of silk comes from the under edge of the cushion, and lies on the cylinder, passing between it and the cushion, and proceeding till it nearly meets the collecting points of the conductor. The more strongly this silk is made to adhere to the cylinder, the stronger is the degree of excitation. Before the cylinder, or opposite to the cushion, is a metallic tube, YZ, supported by a glass pillar LM. This is called the conductor, and sometimes the prime conductor. For the more conveniently trying experiments with this machine, and exhibiting the different states of the cushion and conductor, there are two wires to be fixed occasionally, the one to the conductor, the other to the cushion; on the upper part of these are balls furnished with sliding wires, that they may be set apart from each other at different distances.

80. It is matter of surprise that this simple and very powerful electrical machine should have totally escaped the notice of some modern writers on the subject, who have taken much pains to describe others of far inferior importance. This remark is equally applicable to another form of the cylindrical machine which is but little known, but which has many good qualities to recommend it to the attention of those who prefer the cylinder to the plate machine. The principle on which this machine, as well as that just described, is constructed, is that adopted by Mr. Nairne; but whatever of improvement it possesses is due, we believe, to Mr. Bywater, author of an excellent little work on electricity. The following is Mr. Bywater's own description of this machine: AAAA, fig. 2, is the board on which the supporters and pillars are erected, and by which the machine is made fast with cramps to a table. BBBB are two wooden pillars or supporters, the lower ends of which are morticed into the board AAAA, and in the upper ends of which the axis of the cylinder CCCC turns. DD is the winch by which the cylinder is turned on its axis. EE is a piece of wood, a part of which is slided into a groove under the board AAAA, and made fast by the thumb-screw *f*. GG is a glass pillar, which is fixed to the wood EE, and supports what is called the negative conductor and rubber HH. II is another piece of wood, part of which is slided into a similar groove under the board AAAA, and is made fast by the thumb-screw *j*. KK is a glass pillar fixed into the wood II, and supports the prime conductor LL; to this con-

ductor a number of metallic points are attached, to collect the electric fluid which flows on the surface of the cylinder. M M is a rod of brass inserted in the prime conductor, having a joint by which it may be raised or lowered, to suit the height of the apparatus; this rod is a most useful appendage to the prime conductor. To the upper part of the rubber a piece of black silk is attached, which proceeds from thence over the top of the cylinder, to within about half an inch of the points of the wires inserted in the prime conductor; by which means the fluid that is brought into action by the attrition of the cylinder and rubber is prevented from being dissipated in the air, and carried round with the cylinder to the prime conductor. The action of the silk on the cylinder tends very much to increase the excitation of the machine, as may be seen by removing the cushion a little back from the cylinder, and leaving the silk to act upon it alone, in which case the excitation will often be found to be scarcely less than when the rubber is also in contact with the cylinder.

81. The plate machine, like the cylindrical, has had a few varieties introduced into its construction at different times. The largest specimen of this instrument is that which was constructed by Mr. Cuthbertson, for Tyler's museum, at Haarlem. The following will convey to the reader's mind some idea of the powers of this immense machine; and its construction will be readily understood by the description which we shall add of the most improved form of the instrument. It consists of two circular plates of glass, each sixty-five inches in diameter, and made to turn upon the same horizontal axis, at the distance of seven inches and a half from one another. These plates are excited by eight rubbers, each fifteen inches and a half long. Both sides of the plates are covered with a resinous substance to the distance of sixteen inches and a half from the centre, both to render the plates stronger, and likewise to prevent any of the electricity from being carried off by the axis. The prime conductor consists of several pieces and is supported by three glass pillars, fifty-seven inches in length. The plates are made of French glass, as this is found to produce the greatest quantity of the electricity next to English flint, which could not be produced of sufficient size. The conductor is divided into branches which enter between the plates, but collect the fluid by points only from one side of the plate. The force of two men was required to work this machine; but when it is required to be put in action for any length of time, four are necessary. At its first construction nine batteries were applied to it, each having fifteen jars, every one of which contained about a foot square of coated glass; so that the grand battery, formed by the combination of all these, contained 135 square feet. The effects of this machine are astonishing: but Dr. Van Marum, who principally made experiments with it, imagining that it was still capable of charging an additional quantity of coated glass, afterwards added to it ninety jars of the same size with the former; so that it now contains a coated surface of 225 feet, and the effects are found to be proportionable.

82. The principal objection to the plate machine has hitherto been the difficulty of insulating for the purpose of producing negative electricity. This objection is now removed; and, by using the machine as constructed by Mr. Cuthbertson, both kinds of electricity are produced with ease. The following description of this beautiful and powerful instrument is given by Dr. Brewster in the Appendix to his new edition of Ferguson's Essays. Fig. 3 is a representation of this machine: A B is a circular disc of plate glass, supported upon an horizontal axis, the ends of which rest upon two upright pillars E F. By turning the winch or handle, W, a rotatory motion is given to the plate, which is excited by two rubbers X, Y, fixed at the opposite ends of a diameter of the circle. Each rubber consists of two cushions, which embrace the outer margin of the glass plate, as shown in the figure. The conductor, which is made of brass, is shown at C D, and it is attached to the upright pillar E by the glass rod R. To the right hand of C, and above B, are seen the points for the receiving the electricity from the machine. From each rubber there proceeds to within a little of the points, a flap or double piece of oiled silk, which prevents the dissipation of the electricity.

As it is difficult to insulate the rubbers of the plate machine, without giving it an unseemly appearance, Mr Cuthbertson introduced the practice of insulating the whole machine by the glass supports G, H, I, K, so that negative electricity can thus be obtained as easily as positive.

83. The cylindrical machine, however, being at present in more common use than the plate machine, it is hoped the following remarks may be of use to those who possess such an instrument, and particularly to such as may be disposed to provide themselves with it for the sake of economy. A cylindrical electrical machine ought never to be less than ten inches in diameter; there are cylinders of six, seven, eight, and nine inches diameter, often neatly mounted, and sold by the philosophical instrument makers, but they are of no manner of use for the purpose of experiment, and serve only as a kind of philosophical toy, for the amusement of children, and that too on a very narrow scale. To construct such machines, therefore, is an absolute waste of the materials. With a cylinder of ten inches, properly managed, a tolerable exhibition may be made, but the most convenient size is from twelve to sixteen, the length of the cylinder being in proportion.

84. The most powerful excitation of the machine is produced as follows:—Let the machine be placed within the influence of a good fire, but not so near as to injure any of its parts by the action of the heat. With a flat round pointed knife spread a little amalgam evenly along the cushion, and return it to its place: turn the cylinder a few times round; then take off the cushion, and observe carefully those parts on its surface that have not been touched by the cylinder while revolving; on these parts put a little more amalgam, and repeat the process of turning the cylinder, and supplying the defective parts with amalgam, till every point of that part of the surface of the cushion which presses on the cylinder appears to be properly supplied with

amalgam. Take now a piece of leather about five or six inches square, and spread over one side of it a quantity of amalgam; throw back the silk flap, and, turning the machine gently round, apply the amalgam side of the leather to the cylinder for the space of two minutes or more, as circumstances may require, during which time the excitation will be observed to increase rapidly. The cylinder must next be wiped perfectly clean with an old silk handkerchief, and afterwards with a soft dry linen cloth. Let the cushion be again removed; and the amalgam which appears above and below the line of contact with the cylinder carefully scraped off, the silk flap wiped with a linen cloth, and the whole returned to its place and made fast. If now the cylinder be turned slowly round, streams of the electric fluid will be seen rushing from the silk flap round the lower part of the cylinder, attended with a hissing and snapping noise, while large brushes of the same, of several inches in length, may be observed flying off from the lower edge of the silk into the surrounding air. The machine is now fit for use, and may be fastened to the table, after which the whole of its parts are to be well wiped with a warm and dry linen cloth to free them from dust.

85. The operator, however, must [illegible] expect this high and rich state of excitation [illegible] long duration. The cylinder will soon [illegible] dust will be attracted by the action of the machine; and the moisture produced in the air of the room by the breath of his audience, will, by their united effects, render all his efforts to produce a copious supply of electricity entirely fruitless.

86. To remedy this defect, which gentlemen who deliver public lectures on electricity have often found to be a grievous one, provide a box of thin plate iron, ten or twelve inches long, four inches wide, and one inch and a half in depth, with a lid to fit very easily over it. In this box a piece of bar iron of about six inches in length, three in breadth, and half an inch in thickness, after being heated in the fire to a dull red heat is to be placed, the lid of the box put on, and the whole, on a suitable iron stand, placed under the cylinder, on the board of the machine in a longitudinal direction. The radiation of heat from the iron will effectually preserve the equality of the temperature of the surrounding air for a considerable length of time, and indeed for any length of time required, since, by employing two bars of iron, the one may be kept in the fire while the other is in the box, and thus no other interruption in the course of the experiments will be necessary beyond what is occasioned by the changing of the irons. By this means the machine may be made to act in full vigor under the most disadvantageous circumstances.

87. Dr. Brewster mentions a method used by Mr. Ronalds of aiding the excitation of the machine, which he represents as being attended with the greatest advantages. He thus describes it: In the cylinder machine, the rubber is placed in front of a half cylinder of copper, which communicates with a copper pipe, that serves for the support of the rubber. A very small spirit-lamp, whose burner consists of only one thread of cotton, is placed immediately beneath the mouth or lower end of the copper pipe, so as to keep the rubber and the parts adjacent to it always hot and dry. Besides this contrivance, Mr. Ronalds places his prime conductor upon a glass support, so that a similar spirit-lamp may be placed below it in order to convey heat to its interior.

Mr. Ronalds remarks, that a cylinder machine thus constructed, of half the dimensions of one made upon the usual plan, is highly and permanently effective. The same principle may easily be applied to plate machines. The heat is supposed to assist the excitement by promoting the oxidation of the amalgam.

88. This method may certainly, in some degree, prove beneficial; but it will be found to be in many respects inferior to the simple method above mentioned. In the first place, the radiation of heat will be neither so general nor so great; in the second place, the flame of a lamp or a candle absorbs the fluid; and in the third place, the light, which must necessarily be emitted from two spirit-lamps, would prove highly detrimental to the effect of those experiments which require to be performed in darkness. To which may be added, the expense of the lamps, and the spirit to be consumed.

89. Where a plate machine of large dimensions is used, this additional article will not be required; for the great thickness of the glass renders it capable of retaining the heat much longer than can be done by a thin cylinder; for which reason it must be obvious that, if cylinders were made much stronger than they generally are, their action would be effectual for a greater length of time than it is. Opinion, however, runs in favor of thin cylinders, but the consistency of such opinion remains to be shown. It is well known that the old globular machines, which were made of thick glass, when once put in a state of powerful excitation, retain that state much longer than the modern thin cylinder will do under the same circumstances.

90. The following directions for preparing the amalgam for electrical machines are given by Mr. Singer, in his treatise, already mentioned. Melt in an iron ladle two ounces of zinc with one ounce of tin, and, while this mixture is in a fluid state, pour into it six ounces of mercury; let the whole be then put into an iron or wooden box, and agitated until it be quite cold. It must then be reduced to fine powder in a mortar, and mixed with sweet hogs' lard to the consistence of thick paste. This part of the process need not be performed till the amalgam is wanted for use. This amalgam, he remarks, answers exceedingly well, but, he afterwards adds, I have since made it with a still less proportion of mercury with equal effect. The proportions may be two ounces of tin, four ounces of zinc and seven ounces of mercury. The mercury must be heated to about 300° Fahrenheit, before the fused metals are added to it. When thy amalgam has been agitated until cool, and finely powdered, it is to be mixed with hogs'-lard be trituration in a mortar; and should it at any time become hard, more lard must be added and the trituration be repeated.

91. The application of the electrical apparatus to the purpose of experiment will afford the best

illustration of its subordinate parts; and, in adopting this plan, we shall be enabled to give such an arranged view of the chief properties of the electrical fluid as may be of service in aiding the inexperienced electrician in making an orderly display, instead of a series of experiments which have no regular connexion, and in which sometimes one property, and sometimes another, is illustrated. We shall commence with some observations on the action of the machine itself, and for these we must acknowledge our obligation to Mr. Singer.

92. The machine being prepared according to the directions already given, and the cushion pressed moderately against the cylinder by the action of its adjusting screw, it may be put in motion, and the following phenomena will be observed. 1. Distinct lines of light, accompanied by lateral scintillations, pass from one conductor to the other, across that part of the cylinder which is not covered by the silk flap; these are called electrical sparks. 2. Bright sparks pass between either of the conductors and the knuckle, or any smooth uninsulated substance presented to them at a moderate distance; and if received on the knuckle, or any part of the body, produce a painful sensation. 3. These effects are more distinct, and the sparks from each conductor stronger, when they are taken from both at the same time. 4. The power of the spark from either the positive or negative conductor, singly, will reach its maximum when the opposite conductor is uninsulated, by suspending a chain or wire from it to the ground. 5. If the two conductors are connected by a wire, or other conducting substance, the most vigorous friction of the cylinder will not electrify either. 6. If, instead of a wire, the conductors are connected by a silk string on which a number of shot or metal beads are strung, at the distance of a twentieth of an inch from each other, a series of bright sparks will pass between the beads as long as the turning of the machine is continued. It must be remembered, that the conductor to which the cushion is fixed shows the electrical phenomena of the cushion, and the opposite conductor, that of the electricity of the glass cylinder; hence the observation of their phenomena is properly an observation of the circumstances that occur in all cases when electricity is excited by friction.

93. On these very beautiful phenomena, Mr. Singer makes the following judicious observations. The first and second phenomena seem to show that the cause of electricity is corporeal; for sensation is affected by it, and a mechanical impulse experienced, which it is difficult to ascribe to any other than a material cause. The third phenomenon proves that there is a mutual action between the electricities excited in the opposite conductors; since their effects are more powerful when directed at the same time to one conducting body. The fourth phenomenon shows that the same relation which is observed between the opposite electrified conductors exists also between either of them and the ground, but in a different degree. By the fifth phenomenon it is seen that positive and negative electricity, if excited to the same extent, and united by conducting matter, exhibit no electrical phenomena. The sixth phenomenon is observed to show that when the conductors are connected, the machine continues to excite electricity, but is prevented from displaying it by their mutual contact.

94. From these appearances the following explanation of electrical phenomena may be deduced:—1st. The cause of electrical phenomena is material, and possesses most of the properties of an elastic fluid. 2. This electric fluid attracts and is attracted by all other matter, and, in consequence of such attraction, exists in all known substances. 3d. The attraction of different bodies for the electric fluid is various, so also is that of the same body under different circumstances, consequently the quantity of electricity naturally existing in different substances may be unequal; and the same body may attract more or less than if alone, when combined with other matter: but its original attraction will be restored by destroying the artificial combination. 4th. From some peculiarity in the nature of the electric fluid, its attraction for common matter is more influenced by figure than by substance; and consequently is stronger in extensive than in limited surfaces. 5th. From this pecu- … moves with great facility over the … ough the substance of some bodies, … ed in its progress by others. 6th. … ction of any substance for elec… to the electric fluid it contains, … ubstance will evince no electrical signs; but these are produced when there is either more or less electricity than is adequate to the saturation of the existing attraction: if there be more, the signs will be positive; if less, they will be negative.

95. Electrical excitation then, may be thus effected:—The bodies employed have each a certain quantity of the electric fluid proportioned to their natural attraction for it; this they retain, and appear unelectrified so long as they remain in their natural state. And, if two such bodies are brought in contact, their natural attractions will be altered, one of them attracting more than in its separate state, and the other less; the electric fluid thus diffusses itself amongst them in quantities proportioned to their relative attractions, and hence they appear unelectrified. But if they are suddenly separated, the new distribution of the electric fluid remains, whilst the original attractions are restored, and as these are not equal to each other the bodies will appear electrical; that of which the natural attraction was increased by contact, having received an addition to its quantity of electric fluid, will be positively electrified; and the other will be negative.

### Attraction and Repulsion.

96. The motion of light bodies produced by electricity, is usually called attraction and repulsion, and is occasioned by the mutual attraction existing between the electric fluid and common matter. In practical electricity there are numerous methods of illustrating this motion; the following are some of the principal.

(1). Fix at the end of the prime conductor a knobbed rod, and hang on it two small pith-balls, suspended by threads of equal length. The

balls will now touch one another, the threads hanging perpendicularly, and parallel to each other. But if the cylinder of the machine be turned, by turning the winch, then the pith balls will repel one another, more or less according as the electricity is more or less powerful. If the electrometer be hung to a prime conductor negatively electrified, i. e. connected with the insulated rubber of the machine, the balls will also repel each other. If, in this state of repulsion, the prime conductor is touched with some conducting substance not insulated, the pith balls will immediately come together. But if, instead of the conducting substance, the prime conductor is touched with an electric, as a stick of sealing wax, a piece of glass, &c., then the pith balls will continue to repel each other; because the electric fluid cannot be conducted through that electric.

(2.) Take a small downy feather or a pith ball suspended by a thread, and, holding the thread, bring the ball near an electrified conductor, either positive or negative: the ball will be attracted by the electrified conductor, and adhere to it, until its electricity is destroyed.

Such bodies as are positively electrified, tend to diffuse their superabundant fluid amongst surrounding substances; and those that are negative, endeavour to acquire electric fluid [illegible]ence, either state of electricity will produce attraction; for if light bodies are to be moved, it is indifferent whether the electrified surface attracts their natural electric fluid, or the matter to which it is attached; for the attraction arises only from the different proportions of these in any two bodies, and will of course continue whilst that difference exists.

(3.) Repeat the preceding experiment with a ball or feather supported by a silk thread: the light body will first be attracted to the electrified conductor, and will then recede from it; nor can it again be brought in contact until it has touched some conducting substance. Mr. Singer thus explains the cause of this:—The light body is here attracted for the same reason as before, but it is insulated, and consequently receives, by contact with the electrified surface, a similar electric state; it therefore recedes from that surface, being attracted by the ambient air, or other surrounding bodies; for they have their natural portion of electricity, and therefore differ from the light body, which has either more or less; but the electrified surface does not differ from the light body, and consequently cannot attract it, till, by touching some conductor, its natural electric state is restored.

(4.) The following is a very pleasing variety of the last-mentioned experiment.—Take a glass tube, whether smooth or rough is not material, and, after having rubbed it, let a small light feather be let out of your fingers at the distance of about eight or nine inches from it. This feather will be immediately attracted by the tube, and will stick very close to its surface for about two or three seconds, and sometimes longer; after which it will be repelled; and, if the tube be kept under it, the feather will continue floating in the air at a considerable distance from the tube, without coming near it again, except it first touch some conducting substance; and, if the tube be managed dexterously, you may drive the feather through the room at pleasure. This experiment may be varied as follows: A person may hold in his hand an excited tube of smooth glass, and another may hold an excited rough glass tube, a stick of sealing-wax, or any other electric negatively electrified, at about one foot and a half distance from the smooth glass tube; a feather now may be let go between these two differently excited electrics, and it will leap alternately from one electric to the other.

(5.) Place a leaf of gold, silver, or other metal, on the palm of the hand, and bring it within a few inches of an electrified conductor; it will be attracted and continue to move, alternately from the hand to the conductor, as long as the latter is electrified.

(6.) Suspend from the conductor, by a brass chain, a circular plate of copper, reaching to within an inch and a half or two inches of the table. Directly under this plate place another of the same form, and a little larger, on the table. Turn the machine, and the fluid will pass from the upper to the lower plate. If now small figures cut out of pasteboard, or pith of elder, be introduced between the plates, they will dance about with apparent vivacity, and sometimes appear to course round the edge of the lower plate. This experiment is represented by fig. 4.

(7.) The electrical bells furnish a pleasing illustration of the attraction and repulsion of the electric matter. They are variously constructed, but the form exhibited fig. 5 is the simplest. The two outer bells are suspended by brass chains; the middle bell and the two clappers by fine silk threads. When the bells are attached to the conductor, and the machine is turned very gently, the fluid will pass along the chains to the two outer bells, but will not pass along the silk to the clappers and middle bell. Thus the outer bells being charged with an extra quantity of fluid will attract the clappers, but the moment they touch the bells they become charged, and are repelled with such force as to cause them to strike against the middle bell, on which they deposit their electricity, and are again attracted. By this means a constant ringing is kept up while the machine is turned. From the inside of the middle bell a brass chain passes to the table, for the purpose of conveying away the fluid deposited on it by the clappers. A more elegant form of the electrical bells is thus made:—Fix eight bells near the edge of a circular board supported on four feet, fig. 6, having a glass pillar *e*, in the centre, terminated by a point *g*. On this point place the pointed wires used in the last experiment, hanging from one of them, as *d*, a small glass clapper by a silken thread; and connecting the apparatus by a chain *h*, proceeding from the prime conductor. On setting the machine in motion, the wire will move round, and the clapper ring the bells.

(8.) Place a pointed wire on the machine, electrify the inside of a dry glass tumbler by holding it over the wire whilst the machine is in motion; place some pith balls on the table and cover them with the electrified glass; they will be

alternately attracted by it and the table, and continue their motion for some time. See fig. 7. An instrument is constructed on purpose for this experiment, by which the dancing of the balls may be kept up for any length of time, as it may be connected with the conductor.

(9.) Insulate a circular ring of brass so as to stand about an inch and a half from the flat surface of a table; connect the brass ring with the conductor of the electrical machine, and place within it on the table, a very light and round glass ball of two inches diameter; the ball will be attracted by the ring, touch it, and become electrified at the point of contact; this point will then recede and be attracted by the table, whilst another part of the ball is attracted by the ring; and, by the repetition of this process, the ball is made to revolve and travel round the circumference of the ring.

(10.) Fasten a small piece of sealing-wax on the end of a wire, and set fire to it. Then put the electrical machine in motion, and present the wax, just blown out, at the distance of a few inches from the prime conductor. A number of very fine filaments will immediately dart from the sealing-wax to the conductor, on which they will be condensed into a kind of net-work, resembling wool.

If the wire with the sealing-wax be fixed into one of the holes of the conductor, and a piece of paper be presented at a moderate distance to the wax, just after it has been ignited, on putting the machine in motion, a net-work of wax will be formed on the paper.

If the paper on which the wax is thus received be gently warmed, by holding the back of it near the fire, the wax will adhere to it, and thus the result of the experiment will be rendered permanent. A remarkably fine experiment of the same kind may be made with camphor. Let a silver spoon containing a piece of lighted camphor be made to communicate with an electrified body, as the prime conductor of a machine; while the conductor continues electrified, by keeping the machine in motion, the camphor will throw out numerous ramifications, and appear to shoot like a vegetable.

(11.) Take about a dozen of flaxen threads and tie them together at top and bottom; annex them to the conductor of the electrical machine; when electrified the threads will separate from each other, and the knot at the bottom rising they will assume a spheroidal figure, which will continue as long as they are electrified.

(12.) The following experiment we give as being one of the earliest made by Dr. Franklin in illustration of the principle of attraction and repulsion. Fig. 8 represents an electric jar, having a wire C D E fastened on its outside, which is bent so as to have its knob E as high as the knob A. A is a spider made of cork, with a few short threads run through it to represent its legs. It is fastened at the end of a silk thread, proceeding from the ceiling of the room, or from any other support, so that it may hang mid-way between the two knobs A and E, when the jar is not charged. Let the place of the jar upon the table be marked; then charge the jar, by bringing its knob A in contact with the prime conductor, and replace it in its marked place. The spider will now begin to move from knob to knob, and continue this motion for a considerable time, sometimes for several hours. The inside of the jar being charged positively, the spider is attracted by the knob A, which communicates to it a small quantity of electricity; the spider then becoming possessed of the same electricity with the knob A, is repelled by it, and runs to the knob E, where it discharges its electricity, and is then attracted by the knob A, and so on. Thus the jar is gradually discharged; and, when the discharge is nearly completed, the spider finishes its motion.

## Effect of Points on the Electric Fluid.

97. The facility with which pointed bodies transmit electricity has given rise to several very delicate and beautiful experiments on the electrical apparatus, of which the following are the most deserving of attention.

(1.) *The Electrical Flies.*—These flies are composed of small brass wires, fig. 9, fixed into a cap of brass, easily moveable upon an axis of the same metal, and exactly balanced, so that they may turn with the smallest force. The ends, which ought to be very sharp, are all bent one way, with regard to one another, as those belonging to *a*, *b*, in the figure; though the two sets of points constituting the two flies there represented are contrary to each other; so that the whole flies must have a contrary motion. Fixing the axle with the two flies upon the prime conductor, and working the machine, both will begin to turn very swiftly, each in a direction contrary to that of the points. In this manner, with a powerful machine, several flies may be made to turn either in the same or in contrary directions; and by their gradual increase or decrease in size may represent a cone or other figure; for the course of each will be marked by a line of fire, and thus the whole will exhibit a beautiful appearance in the dark. The light is more brilliant when the ends are slightly covered with sealing-wax, grease, or other electric matter. The flies, in this experiment, turn the same way whether the electricity be positive or negative; the reason of which is that in positive electricity the fluid issues from the body electrified, and that in negative electricity it enters into it. In the former case, the recoil of the fluid, which acts equally on the air and on the point from whence it issues, must continually urge the point the contrary way; and in negative electricity, when the point solicits a continual draught of electric matter from the air, the direct impulse of the former must also produce a motion in the point in the course in which the fluid itself moves. In vacuo no motion is produced; because there is no air on which the fluid may act when it issues from the point.

(2.) *The Electrical Orrery*, fig. 10, is another instrument frequently used for showing the effect of points in the transmission of the electric fluid. The principle of its action is this: the ball S represents the sun, E the earth, and M the moon, connected by wires *a c* and *b d*; *b* is the centre of gravity between the earth and moon. These three balls and their connecting

wires are hung and supported on the sharp point of a wire A, which is stuck upright in the prime conductor B of the electrical machine; the earth and moon hanging upon the sharp point of the wire *c a e*, in which wire is a pointed short pin, sticking out horizontally at *c*; and there is just such another pin at *d*, sticking out in the same manner, in the wire that connects the earth and the moon.

When the cylinder of the electrical machine is turned, these balls and wires are electrified; and the electrical fire, flying off horizontally from the points *c* and *d*, causes S and E to move round their common centre of gravity *a*, and E and M to move round their common centre of gravity *b*. And as E and M are light, when compared with S and E, there is much less friction on the point *b*, than S and E make about the point *a*. The weights of the balls may be adjusted so, that E and M may go twelve times round *b*, in the time that S and E go once round *a*.

(3.) *The Electrical Inclined Plane* affords another and a still more beautiful illustration of the same thing, showing also that a stream of the electric matter issuing from points possesses force sufficient to counteract the power of gravitation in light bodies. Fig. 11 represents the inclined plane, where A is a board of mahogany, fourteen inches long and [illegible] inches broad; BBBB are four glass pillars, three-tenths of an inch in thickness; the length of the two longer is seven inches, and that shorter is five inches.

From the longer to the shorter pillars are stretched two fine brass wires, parallel to each other, and tightened by screws which pass through the brass balls which surmount the pillars. On these wires the axis of the fly C rests, the ends of which are formed like a small pulley, having a groove in them to prevent their slipping off the wires, and to guide the fly when in action. It is obvious that, if the fly be placed on the upper part of the wires, it will roll down them by its own gravity; but when it has reached the bottom of the plane, if the upper end of the wires be connected with the machine while in action, the escape of the fluid from the points will cause it to roll very rapidly up the plane till it reach the top of it. These experiments may be varied to a great extent, and models of corn-mills, water-pumps, astronomical clocks, &c., constructed of cork and pasteboard are readily put in action by directing against their main wheels a stream of electricity from a strong pointed wire inserted into the prime conductor.

(4.) By a fine flaxen thread attach a large downy feather to the prime conductor of the machine; turn the cylinder gently round, and the fibres of the feather will repel each other; approach it with a brass ball, or with the closed hand, and it will endeavour to turn itself towards the ball or hand; but present a pointed wire to it, and it will instantly shrink from it back on the conductor, as if animated, which arises from its being suddenly deprived of its electricity by the point. This experiment may be varied by inserting the brass stem of fig. 12, into one of the holes in the prime conductor. The action of the machine will cause the hairs on the head to diverge from each other, and to stand on end.

98. Such, says Mr. Singer, are the principal phenomena of motion produced by the action of electricity; they are susceptible of almost unlimited variety, but uniformly result from the simples already stated, namely, the attraction of the electric fluid for common matter, its tendency to equal diffusion; and the occasional interruption of these properties by non-conducting power and altered force of attraction.

### Luminous Exhibition of Electricity.

99. It may be necessary to observe here that all experiments made for the purpose of displaying the brilliancy of the electric matter, in passing from one conducting substance to another, should be made in a darkened room, as the presence of either natural or artificial light robs them of more than half of their beauty. The articles of apparatus, too, must be all free from dust, and perfectly dry, besides being a little warm, otherwise the effect expected will not result; we think it particularly necessary to observe that in any experiment requiring the exhaustion of glass vessels the above precautions are peculiarly needful, as we have seen some of the following experiments utterly fail in the hands of public lecturers merely from inattention to them. 135

100. To render the electrical fluid luminous it must be collected in considerable quantities, and the brilliancy of the display will depend on the particular configuration of the conducting surface over which it is made to pass. The light evolved in ordinary cases, says Mr. Singer, extends only to faint flashes and scintillations, sparks being only produced when these effects are concentrated, as they are in the electrical machine by the action of its conductors.

101. There are three circumstances that influence the electric spark in its passage from one conductor to another, namely, the form of the conductors, their extent, and the nature and density of the medium through which the spark passes. The following remarks on these three circumstances we give nearly in Mr. Singer's own words.

102. The distribution of electricity on conductors has but little relation to their solid contents, and depends almost entirely on extent of surface, for the same effects are produced by the thinnest cylinder or sphere of metal as by the most compact solid body of the same form and dimensions; it is probable that the action of insulated conductors consists in the ready communication of their electric state to the contiguous surface of the extensive stratum of air by which they are surrounded, and to the facility they present to the discharge of that electrified stratum when an uninsulated or differently electrified body is brought near them; for every positively electrified conductor is surrounded by a positive atmosphere, and every negative conductor with a negative atmosphere whose densities decrease as the square of their increased distance. Hence any insulated electrified body will retain its electrical state until its intensity is sufficient to

overcome the resistance of the air, and the greater or less interval through which the spark passes is called the striking distance.

103. When the surface of the conductor is uniform, the re-action of the air around it is also uniform; but if the surface of the conductor be irregular, the tendency of the electric fluid to escape or enter it will be greatest at the most prominent parts, and most of all when these are angular or pointed. To understand this it is only necessary to recollect that every electrified conductor is surrounded by an atmosphere of its own figure, the contiguous surface of which is similarly electrified: and that electricity is not transmitted through air, but by the motion of its particles.

104. For this motion of particles is resisted by a uniform surface from the similar action of the air around it, which is all equally capable of receiving electricity, and cannot tend to distribute it in one direction more than another; the immediate electrical atmosphere of the conductor will be therefore resisted in any attempt to recede from it by a column of air which is equally opposed in every part; but if there be any prominent point on the conductor projecting into the atmosphere, it will facilitate the recession of the electrified particles opposite to it by removing them farther from the electrified surface, and opposing them to a greater number of such as are unelectrified.

105. The action then, of bodies that are pointed or angular, appears to consist in promoting the recession of the particles of electrified air, by protruding a part of the electrical atmosphere of the conductor into a situation more exposed to the action of the ambient unelectrified medium, and thereby producing a current of air from the electrified point to the nearest uninsulating body. Hence the most prominent and the most pointed bodies are such as transmit electricity with the greatest facility, for with them this condition is most perfectly obtained.

106. A spherical surface is that which, considered with regard to its surrounding atmosphere, is most uniform; hence balls, or cylinders, with rounded ends, are naturally employed for insulated conductors, and their magnitude is proportioned to the intensity of the electrical state they are intended to retain; for a point is but a ball of indefinite diameter, and will act as such on very small quantities of electricity; and a ball of moderate size may also be made to act as a point by electrifying it strongly.

107. If two spheres of equal size are connected together by a long wire and electrified, their atmospheres will extend to the same distance, and they will of course have respectively the same intensity; but if the spheres be of unequal size, the atmosphere of the smallest will extend furthest, and it will necessarily have the greatest intensity; so that a longer spark can be drawn from a small ball annexed to the side of a conductor than from the conductor itself, and longer in proportion as the ball projects farther from the side. Hence the finer the point, and the more freely it projects beyond any part of the conductor to which it is annexed, the more rapidly will it receive or transmit electricity.

108. Let, for example, a fine point be fixed in the axis of a large brass ball, from beneath the surface of which it may be protruded more or less by the action of a fine screw, the effect of a ball of any size may be obtained; when beneath the surface of the ball the point does not act, but in proportion as it is protruded it increases the transmitting power, and, if projected far enough, at length entirely overcomes the influence of the ball.

109. The same writer gives the following experiments, among others, for illustrating the influence of the form and extent of the conductor on the appearance of the electric spark.

(1.) Present a brass ball of about three inches in diameter to the positive conductor of a powerful electrical machine; sparks of brilliant white light will pass between them, accompanied by a loud snapping noise: to produce these sparks in rapid succession the ball must be brought near the conductor, and they then appear perfectly straight.

(2.) Annex a ball of an inch and a half or two inches diameter to the conductor, so as to project three or four inches from it; present the large ball to this, and much longer sparks will be obtained than from the conductor itself, but they will be less brilliant and of a zigzag form.

(3.) Substitute a small ball for that used in the former experiment; the fluid will now pass to a greater distance, but in the form of a divided brush of rays faintly luminous, and producing little noise; this brush will even occur with larger balls, if the machine be very powerful; it is most perfect when procured by presenting a flat imperfect conductor, as a piece of wood or paper.

(4.) Whilst a current of sparks is passing between a large ball and the conductor, present, at the distance of about an inch and a half, a sharp point at double that distance, and the sparks will immediately cease, the electric matter being silently drawn off by the point.

110. The brilliancy of the electric spark is always in proportion to the conducting power of the bodies between which it passes; hence metals are almost exclusively employed for this purpose, as wood and other imperfect conductors produce only faint red streams; yet these substances act as points with some efficacy, and the particles of dust which collect around the apparatus are often troublesome to electricians from the same cause.

111. The nature and density of the medium through which the electric spark passes has also a powerful influence on its character. Dr. Watson seems to have been the first who made experiments on this subject; these he conducted on a very large scale, and he describes the results as having been very beautiful; they will be noticed in another part of this article.

112. The following is a description of the simple apparatus used by Mr. Singer for showing the effect of different gaseous mediums on the passage of electricity. It consists of a glass globe, fig. 1, plate II., of about four inches diameter, having two necks capped with brass; to one of the necks a stop-cock is screwed, with a wire and ball projecting into the globe; another

ball is attached to a wire that slides through a collar of leathers screwed to the opposite cap, so that the balls may be set at any required distance from each other within the globe. This apparatus may be exhausted by connecting the stop-cock with an air-pump, and various gases may be introduced into it, or the air it contains may be rarefied or condensed, and the effect of these processes on the form of the spark examined. In condensed air the light is white and brilliant; in rarefied air, divided and faint; and in highly rarefied air, of a dilute red or purple color. The effect of gases seems to be proportioned to their density; in carbonic acid gas the spark is white and vivid, in hydrogen gas it is red and faint.

113. The brilliancy of the electric spark seems to be in proportion to the density of the medium through which it is made to pass. This is proved by the following experiments:—1. Fix with cement a short iron or platina wire within one end of a glass tube thirty inches long, so that the wire may project a little way within the tube, and fix a small brass ball on the outer extremity of the wire. Fill the tube with mercury, and at the open end place a drop of ether, which secure by the point of the finger while the tube is inverted in a vessel of mercury, so as to form a Torricellian vacuum in the upper part. The ether will rise to the top; and upon the removal of the finger, and the fall of the mercury, will expand into vapor. If now electricity be transmitted through this vapor, it will be rendered luminous, and assume various hues according to its strength. When the spark is strong, and has to pass through some inches of the expanded vapor, the light is usually of a beautiful green color. 2. Take an air-pump receiver twelve or fourteen inches high, and six or seven inches in diameter; adapt a wire, pointed at its lower extremity, to the top of the receiver, letting the point project about two inches into its inside; place the receiver on the plate of the air-pump, and electrify the wire at its top positively; whilst the air remains in the receiver, a brush of light of very limited size only will be seen, but in proportion as the air is withdrawn by the action of the pump it will enlarge, varying its appearance and becoming more diffused as the air becomes more rarefied; until at length the whole of the receiver is filled by a beautiful blush of light, changing its color with the intensity of the transmitted electricity. 3. Into a piece of soft deal about three inches long and an inch and a half square, insert two pointed wires obliquely into its surface at nearly an inch and a half distance from each other, and to the depth of an eighth of an inch; the wires should incline in opposite directions, and the track between the points be in that of the fibres; a spark in passing from one point to another through the wood will assume different colors in proportion as it passes more or less below the surface; and by inserting one point lower than the other, so that the spark may pass obliquely through different depths, all the prismatic colors may be made to appear at once. Sparks taken through balls of wood or ivory appear of a crimson color; those from the surface of silvered leather are of a bright green; a long spark taken over powdered charcoal is yellow; and the sparks from imperfect conductors have a purple hue. The quantity of air through which these sparks are seen also influences their appearance; for the green spark in the vapor of ether appears white when the eye is placed close to the tube, and reddish when it is viewed from a considerable distance.

114. When metallic conductors are of sufficient size and perfectly continuous, they transmit electricity without any luminous appearance; but if the continuity be interrupted in the slightest degree a luminous effect is produced, a bright spark occurring at every separation. Various articles of apparatus are used for the exhibition of this effect, according to the fancy of the operator; the following are those used in general by public lecturers:—1. The spiral tube: this instrument is represented by fig. 2, and is composed of two glass tubes C D, one within another, and closed with two knobbed brass caps A and B. The innermost of these has a spiral row of small round pieces of tin-foil stuck upon its outside surface, and lying at about one-thirtieth of an inch from each other. If this instrument be held by one of the extremities, and its other extremity be presented to the prime conductor, every spark that it receives from the prime conductor will cause small sparks to appear between all the round pieces of tin-foil stuck upon the innermost tube; which in the dark affords a beautiful spectacle, the tube appearing encompassed by a spiral line of fire. Fig. 3 represents several spiral tubes placed round a board, in the middle of which is screwed a glass pillar, and on the top of this pillar is cemented a brass cap with a fine steel point. In this a brass wire turns, having a brass ball at each end, nicely balanced on the wire. To make use of this apparatus, place the middle of the turning wire under a ball proceeding from the conductor, so that it may receive a succession of sparks from the ball; then push the wire gently round; and the balls in their relative motions will give a spark to each tube, and thereby illuminate them down to the board, which from its brilliancy and rapid motion, affords a most beautiful and pleasing sight. Fig. 4 is another instrument for showing the same effect in a diversified form: the action being in this case the same as in the preceding, no further explanation is necessary. The beauty of this kind of exhibition is sometimes much increased by laying down the devices on glass stained of different colors. There are other methods of rendering the electric fluid visible in a very pleasing manner, some of which we shall here enumerate.

115. The luminous conductor, as represented at fig. 5, consists of a glass tube about eighteen inches long, and four in diameter, to the ends of which are cemented the hollow brass pieces D F, E B, the former having a point, C, for receiving electricity from the electrical machine, while the other has a wire terminating in a ball, G, from which a strong spark may be drawn. From each piece a knobbed wire proceeds within the cavity of the glass tube. One of these brass pieces is composed of two parts, in one of which is a valve covering a hole by

which the tube may be exhausted of its air. The whole is supported on two glass pillars fixed in a wooden frame. When this tube is exhausted of its air, and the point C set near the machine, this point will appear illuminated with a star, while the glass tube will exhibit a weak light on its inside; and, from the knobs within the glass, the appearance of positive and negative light will be evident, as the knob at D will show a bright pencil of rays, and the opposite knob a round star. If the point C, instead of being presented to the cylinder, or the positive conductor, be placed near the rubber or negative conductor, the appearance of the light from the internal knobs will be reversed.

116. The visible electrical atmosphere is exhibited by the apparatus represented at fig. 6, where G I represents the receiver with the plate of an air-pump. In the middle of the plate I F a short rod is fixed, having at its top a ball B, whose diameter is nearly two inches. From the top of the receiver another rod A D with a like ball A proceeds, and is cemented air-tight into the neck C; the distance of the balls from one another being about four inches. If, when the receiver is exhausted of air, the ball A be electrified positively, by touching the top D of the rod A D with the prime conductor, or an excited glass tube, a lucid atmosphere appears about it, which, although it consists of a feeble light, is yet very conspicuous, and very well defined; at the same time the ball B has not the least light. The atmosphere does not exist all round the ball A, but reaches from about the lower half of it. If the rod, with the ball A, be electrified negatively, then a lucid atmosphere, like the above described, will appear upon the ball B, reaching from its middle to a small distance beyond that side of it that is towards the ball A; at the same time the negatively electrified ball A remains without any light.

117. Fig. 7 represents a mahogany stand, so constructed as to hold three eggs at a greater or smaller distance, according to the position of the sliding pieces. A chain C is placed at the bottom, in such a manner as to touch the bottom of the egg at B with one end, and with its other the outside coating of a charged jar. The sliding wire A at the top is made to touch the upper egg; and the distance of the eggs asunder should not exceed a quarter or the eighth part of an inch. The electric spark, being made to pass down by means of the discharging rod through the wire and ball at A, will, in a darkened room, render the eggs very luminous.

### Accumulation of Electricity.

118. Although the electricity we have already described be sufficient for the performance of many very fine experiments, and for enabling us to investigate the nature and properties of the electric fluid; yet the full energy of this wonderful agent can only be displayed when it is collected in great quantities, and made to operate on substances in a strongly concentrated state. This, it might be supposed, would be best effected by diffusing the electrical matter over very extensive conductors, and at once discharging the quantity thus accumulated, on the subject of experiment: but such is not the case, since the extension of the surface of any conducting body diminishes its intensity. This fact is admirably illustrated by Mr. Singer in the following experiment.

119. Insulate a flat metal plate with smooth rounded edges, and connect with it a pith-ball electrometer; electrify the plate, and the balls will diverge: bring a similar plate uninsulated near that which is electrified, keeping their flat surfaces parallel and opposite to each other; the balls of the electrometer gradually collapse as the plates approach, and, when they are within about half an inch of each other, the insulated plate appears unelectrified; but, on the removal of the uninsulated plate, the original divergence is restored. See fig. 8.

120. When the insulated conductor, he adds, is electrified, its pith-balls separate, because they are in a different electrical state to the air by which they are surrounded, the fluid of which they attract; but all unelectrified bodies have the same relation to the electrified balls like the ambient air, and such as are conductors and connected with the ground present a more ample source of matter and electricity; consequently, if such bodies are brought near the electrified conductor, its attraction is exerted on them, and the influence of the surrounding air is proportionally diminished; and if the proximity be sufficient, the attraction of the electrified surface will be so exclusively exerted in that direction as to be imperceptible in any other.

121. In the above experiment the bodies are not brought in contact, but only near each other, and consequently there is no communication or loss of electricity, but merely a compensation of its attractive power; hence, when the uninsulated plate is removed, the divergence of the electrometer is restored.

122. The grand instrument used by electricians for the accumulation of electricity is denominated the Leyden jar, or phial: its construction has already been in some measure described, but it may be necessary still further to explain it, and to make some remarks on the principle of its action.

123. *The Leyden Jar* in whatever form it may be constructed is nothing more than an electric placed between two non-electrics. The following description of this remarkable instrument is from Mr. Cavallo's treatise on electricity. If, says he, to one side of an electric, sufficiently thin, as for instance a pane of glass, a piece of sealing-wax, &c., be communicated one electricity, and to the opposite side the contrary, that plate in that case is said to be charged; and the two electricities can never come together except a communication of conducting substances be made between both sides, or the electric be broken by the power of electric attraction. When the two electricities of a charged electric are by any means united, and therefore their power destroyed, that electric is then said to be discharged and the act of union of these two opposite powers is called the electric discharge.

124. To avoid the difficulty of communicating electricity to an electric plate, it is customary to coat the sides of it with some conducting sub-

stance, as tin-foil, gilt paper, &c., by which means the charging and discharging becomes very easy; for when the electricity is communicated to one part of the coating, it is immediately spread through all the parts of the electric that are in contact with that coating; and, when the electric is to be discharged, it is sufficient to make a conducting communication between the coatings of both sides, to discharge entirely the electricities of that electric.

125. When plates of glass are thus coated, it is of essential importance that the glass should extend two or three inches beyond the metal coatings; for, although they do not absolutely touch one another, yet, when they are electrified, the electricity will easily force a passage through the air, and by passing over the surface of the electric, from one coating to the other, render it incapable of receiving any charge.

126. If a glass plate be properly coated on both sides with a conducting substance, and if to one of these coatings be communicated some electricity, the other coating, while communicating with the earth, or with other conducting bodies, acquires by itself an equal quantity of the contrary electricity; but if, while one side is acquiring electricity, the opposite side does not communicate with the earth, or the conducting substances, the glass cannot be charged. The reason of this is founded on the property of bodies to acquire an electricity, contrary to that possessed by a contiguous electrified body; and the cause that hinders these two electricities from mixing, is the interposition of the glass plate which is impermeable to electricity. Although if the glass be too thin, or the charge too high, the strong attraction, between the positive and negative electricities, forces a passage through the glass and discharges it.

127. The most usual, and by far the most convenient form of the Leyden jar is that represented at fig. 9. It is coated on the inside and also on the outside with tin-foil to within two inches and a half of the top. With the inside coating a wire is connected which rises through a lid of baked wood neatly fitted into the mouth of the jar, and terminating in a smooth brass ball. The uncoated part of the jar must be kept perfectly clean and dry, otherwise the action will be very incomplete. The coating is best fastened on with very strong gum water, but some electricians use common paste; and in some instances the tin-foil is first pasted upon paper, and afterwards on the glass: this is considered an improvement both as it respects the facility of drying the gum or paste, and also the strengthening of the jar.

128. If a jar thus constructed be held in one hand by the lower part, and the knob applied to the prime conductor when the machine is in action, it will become charged in a few seconds; and if then a communication be formed between its outside and inside coatings, by touching the ball with the other hand, a smart explosion takes place, and a peculiar and painful sensation is felt chiefly at the wrists and elbows, and across the breast: this sensation is called the electric shock, and it may be communicated to any number of individuals, holding each other by the hand and forming the line of communication between the coatings of the jar. In this way the abbé Nollet succeeded in giving the shock to 180 of the French Guards in the king's presence.

129. When it is wished to discharge the jar without allowing the charge to pass through the body, an instrument is used called the discharging rod, which is composed of a bent wire or two branches, connected by a joint, and furnished with a glass handle. The extremities of the rod or branches are pointed, but have screws, by means of which they are fitted with balls. In discharging a jar with this instrument, it is held by the glass handle, and, while one end is applied to the outer coating of the jar, the other is made to approach the ball of its wire, and thus the electricity passes through the metallic part of the discharger from the one coating to the other of the jar. If the extremities be without their balls the discharge is effected without noise, but otherwise there takes place an explosion, more or less loud according as the jar is more or less charged. The neatest form of the discharging rod is that represented at fig. 10; where AA is the glass handle by which it is held, and BC are the two branches with their balls.

130. When the accumulation of great quantities of electricity is required, the instrument then made use of is termed the electrical battery, and is composed of a number of Leyden jars connected together and placed in an appropriate box. The most modern construction of the battery, is represented at fig. 11. It consists of twelve jars placed in a mahogany box, the bottom of which is covered with tin-foil, for the purpose of connecting together all the outside coatings; the inside coatings being connected together by the wires and balls that rise from their centres, and are united together at the top. On one side of the box there is a small brass hook A for the purpose of connecting the battery by means of a chain with any substance through which the discharge is to be made; this hook passes through the box and is fixed in contact with the tin-foil which connects the exterior coating of the jars.

131. A battery may also be constructed by a combination of panes of glass properly coated. Dr. Franklin formed a battery of this kind with eleven panes of common window-glass, and with it he made the greater part of his experiments.

132. In whatever form batteries are constructed they are charged and discharged in the same manner as a single jar. If one of the knobs of the battery communicate with the prime conductor of the machine in a state of action, it will soon be charged; and the discharge may be effected by making a communication between the coatings, by means of a discharging rod, or any other conductor.

133. Batteries of great size have been constructed by different electricians, so as to accumulate an enormous quantity of electricity, capable of melting the hardest metals, and of putting an instantaneous termination to animal life. Dr. Priestley constructed a battery consisting of sixty-four jars, and containing thirty-two square feet of coated surface. Mr. Cuthbertson completed, in 1784, for the Teylerian Museum at Haarlem, a battery of 135 jars and 132 feet

of coated surface; and in 1789 he completed another battery for the same institution, consisting of 100 jars, and containing 550 feet of coated surface.

134. It is of the utmost importance that a practical electrician should be expert in constructing batteries, and in coating jars himself, not only because of the expense attending the employment of others, but because they may often be at too great a distance from workmen who are accustomed to operations of this kind. A difference of opinion exists with respect to the size of the jars and the kind of glass they are to be made of. Fine flint or crystal glass may be used with greater advantage than any other; but the expense becomes a very considerable object, especially as the jars of a battery are very apt to break by the inequality of their strength; for the force of the fluid in a battery is equally distributed among all the bottles, however their capacities may differ. Thus, if we express the quantity of charge which one jar can easily receive by the number 10, we ought not to combine such a jar in a battery with another whose capacity is only 8; because the whole force of electricity expressed by 10 will be directed also against that the quantity of which is only 8; so that the latter will be in danger of being broken. It will be proper, therefore, to compare the jars with one another before putting them together in a battery.

135. Besides the consideration of the absolute capacity which each jar has of receiving a charge, the time which is taken up in charging it must also be attended to; and the jars of a battery ought to be as equal as possible in this respect as well as in the former. The thinner a glass is, the more readily it receives a charge, and vice versa; but it does not follow that, on account of its thickness, it is capable of containing a greater charge than a thicker one. The reverse is actually the case: and though a thick glass cannot be charged so quickly as a thin one, it is nevertheless capable of containing a greater power of electricity. If the thickness of the glass be very great, no charge can, indeed, be given it; but experiments have not yet determined how great the thickness must be which will prevent any charge. Indeed it is a fact, that, though a thick glass cannot be charged by a weak electric machine, it may be so by a more powerful one; whence it seems reasonable to suppose, that there is no real limit of this kind; but that if machines could be made sufficiently powerful, glasses of any thickness might be charged.

136. The expense of constructing large batteries is an object of great importance, and has led some electricians to devise a cheaper method of making them than is commonly used. Among those who have thus labored must be mentioned Mr. Brooke of Norwich, who introduced batteries of green glass bottles, instead of flint glass jars. Some of them consisted of nine bottles; but when a greater power was required more were added. Jars would have been preferred to bottles, on account of their being more easily coated; but, being less easily procured, he was content to put up with this inconvenience. The mean size of these bottles was about eight inches in diameter; they were coated ten inches high, and made of the thickest and strongest glass that could be procured, weighing from five pounds and a half to seven pounds each. In the construction of a battery of twenty-seven bottles, he disposed of them in three rows; nine of the stoutest and best composing the first row, nine of the next best being disposed in the second, and the third containing the nine weakest. These were all of green glass, but not of the same kind. Some of those in the front row were composed of a glass like that of which Frontigniac wine bottles are made; and this kind of glass seemed to be by much the best, as being both harder and stronger, and less liable to break by a high charge. The second and third rows of the battery consisted of bottles the diameter of which was from six and a half to ten inches, and which were coated from eight and a half to eleven inches high; none of their mouths being larger than an inch and a half, nor less than three quarters of an inch. The bottles of which Mr. Morgan made use were not coated all over the surface usually coated, but slips of tin-foil were laid on of about three quarters of an inch in breadth, at the distance of about a slip between each: a circumstance which clearly shows that a perfectly continuous coating is not of essential importance.

137. We have already noticed that the uncoated intervals of the Leyden jar should be clean and dry; but this must be understood with some limitation, as if it be perfectly clean and so dry as to approach to warmness, an explosion will take place between the coatings over the glass, and thus occasion a loss of the charge with a great waste of time. These effects may be prevented by breathing on the glass through a piece of barometer tube, but much more effectually by pasting a slip of writing paper, an inch broad, on the inner surface of the jar, close to the upper edge of the coating. By this means the intensity of the charge is diminished at the very spot where its tendency to explode is the greatest. The breadth, however, of this rim of paper must be proportioned to the size of the jar. Some prefer varnishing the uncoated part of the jar, in which case the varnish must be of the very finest quality.

138. The precarious process of charging very large batteries to a high degree of intensity is well known to those who have had to make very powerful experiments with them; and, as frequent fractures of jars take place, it may be of importance to the practical electrician to know how to repair them when they are but slightly injured; although, at the same time, we would rather persuade him to substitute a new jar than to undergo the very troublesome and expensive process of repairing, by cement, one that has been burst.

139. The following is the method adopted by Mr. Brooke for repairing the bottles of his battery when they become injured. Take, he says, of Spanish white eight ounces; heat it very hot in an iron ladle, to evaporate all the moisture; and when cool sift it through a lawn sieve; take three ounces of pitch, three quarters of an ounce of resin, and half an ounce of bees'-wax; heat them all together over a gentle fire, stirring the whole

frequently for nearly an hour; then take it off the fire, and continue the stirring till it is cold and fit for use.

140. To the above account of the electrical battery we shall here add Mr. Morgan's rules for its construction. They are the following.

141. Its connecting wires should be perfectly free from all points and edges.

142. They should be easily moveable, so that when accident has lessened the number of jars, the number of wires may be reduced so as to correspond with the remaining quantity of glass.

143. The jars should not be crowded; for in such a case, if necessity should oblige us to employ jars of different heights or sizes, the tin-foil of the higher ones, being in contact with the uncoated glass of the lower ones, the insulation will thus be rendered less complete.

144. The size of the jars should not be large; for though an increase of magnitude lessens the trouble of cleaning the battery, it at the same time increases the expense of repairing damages which frequently occur.

145. The several wires should be fixed very steadily, or in such a manner as not to admit of any shaking.

146. The battery should take up the least possible room; for as it increases in size, so is the probability increased of its being exposed to the influence of surrounding conductors.

147. The strength of the charge that can be produced by either a single jar or a battery is estimated according to the number of square feet of coated surface in each. Hence arises the necessity of forming a combination of jars, as single ones of convenient size cannot be obtained. One of the largest, perhaps, ever constructed was used by Mr. Singer in his lectures on electricity. This jar, he informs us, was eighteen inches in diameter, and two feet in height; its external coating exposing a surface of about six square feet. The principal experiments performed by the aid of the electrical battery will be explained in another part of this article.

### Instruments for Measuring Electricity.

148. The instruments used for the purpose of ascertaining the presence of electricity, and measuring its intensity, are denominated electrometers, and hold a very important place among the necessary articles of electrical apparatus. Some of these are so constructed as to be of use only in indicating the presence of electricity; others perform the two-fold office of showing its presence, and indicating the precise degree of its intensity at the same instant; while others are constructed for the purpose of exactly measuring the strength of, and giving the required direction to any accumulation of the electric matter, from the charge of a small phial to that of the most powerful battery. We shall here give a very brief description of the principal of these useful instruments.

149. The first electrometer is generally allowed to have been that of the abbé Nollet; it was composed of two silk threads, which were made to recede from each other on being approached by an electrified body. The angle of the divergency of the threads was observed by the shadow which they cast on a flat surface placed behind them. This was certainly a very simple apparatus, though, at the same time, very imperfect: it was improved by Mr. Waitz, who appended small weights to the threads.

150. The electrometer of Mr. Canton consisted of a pair of small pith-balls suspended by very fine flaxen threads from a peg enclosed in a small box having a sliding cover fitted to it; when he used this instrument the lid was drawn off, the box held horizontally, so that the balls might hang freely. A more complicated instrument, but founded on the same simple principles, and containing four electrometers, is represented in fig. 12. A is the basis of the stand which supports these, and is made of mahogany. B is a pillar of wax, glass, or baked wood. To the top of the pillar, if it be of wax or glass, a circular piece of wood, C, is fixed; but if the pillar be of baked wood, that may constitute the whole. From this circular piece of wood proceed four arms of glass, or baked wood, suspending at their ends four electrometers, two of which, D, E, are silk threads about eight inches long, suspending each a small downy feather at its end. The other two electrometers, F, G, are made of very small balls of cork, or of the pith of elder; and they are constructed in the following manner:—*a b* is a rod of glass about six inches long, covered with sealing-wax, and formed at top into a ring: from the lower extremity of this stick proceed two fine linen threads, *c c*, about five inches long, each suspending a cork or pith-ball *d*, about one-eighth of an inch in diameter. These threads should be moistened with a weak solution of salt. When this electrometer is not electrified, the threads *c c* hang parallel to each other, and the cork balls are in contact; but when electrified they repel one another, as represented in the figure. When it is inconvenient to use the insulating stand, A B, the electrometers may be easily supported by a glass rod or tube.

151. Electrometers constructed of pith of elder were employed by Mr. Cavallo in many of his experiments in electricity, particularly in those on the electricity of the atmosphere. One of these instruments is represented in figs. 13 and 14. The case or handle of this instrument is formed of a glass tube, about three inches in length, and three-tenths of an inch in diameter, one-half of which is coated with wax on the outside. From one extremity of this tube, viz. that without sealing-wax, a small loop of silk proceeds, which occasionally serves to hang the electrometer on a pin, &c. To the other extremity of the tube a cork is adapted, which, being cut tapering on both ends, can fit the mouth of the tube with either end. From one extremity of this cork two linen threads proceed, a little shorter than the length of the tube, suspending each a little cone of pith of elder. When this electrometer is to be used, that end of the cork which is opposite to the threads is pushed into the mouth of the tube; the tube then forms the insulated handle of the pith electrometer, as represented in fig. 13. But when the electrometer is to be carried in the pocket, the threads are put into the tube, and the cork stops it, as repre-

sented in fig. 14. The advantages of this electrometer are, its convenient small size, its great sensibility, and its continuing longer in good order than any other. Fig. 15 represents a case to carry the above described electrometer in. This case is like a common toothpick-case, except that it has a piece of amber fixed on the extremity A, which may occasionally serve to electrify the electrometer negatively; and on the other extremity a piece of ivory fastened upon a piece of amber B C. This amber serves only to insulate the ivory; which, when insulated, and rubbed against woollen cloths, acquires a positive electricity, and is therefore useful to electrify the electrometer positively.

152. Another form of the pith-ball electrometer is that invented by Mr. Henley; it is simple in its construction, and extremely useful in numerous experiments, as will afterwards appear. It consists (fig. 16) of a perpendicular stem formed at top like a ball, and furnished at its lower end with a brass ferrule and pin, by which it may be fixed in one of the holes of the conductor, or at the top of a Leyden jar. To the upper part of the stem, a graduated ivory semicircle is fixed, about the middle of which is a brass arm or cock, to support the axis of the index. The index consists of a very slender rod, which reaches from the centre of the graduated arch to the brass ferrule; and to its lower extremity is fastened a small pith-ball nicely turned in a lathe. When this electrometer is in a perpendicular position, and not electrified, the index hangs parallel to the pillar; but when it is electrified the index recedes more or less according to the quantity of electricity, from the stem. Fig. 17, represents this electrometer separated from its stand, and fixed upon the prime conductor. The scale in Mr. Henley's quadrant is divided into equal parts; but M. Achard has shown that, when this is the case, the angle at which the index is held suspended by the electric repulsion is not a true measure of the repulsive force; to estimate this force truly, he demonstrates that the arc of the electrometer should be divided according to a scale of arcs, the tangents of which are in arithmetical progression.

153. One of the most useful electrometers for indicating the presence of very small portions of electricity, is that invented by the Rev. Mr. Bennet. The common construction of this instrument is very good; but a highly improved form of it is described by Dr. Brewster in the appendix to his new edition of Ferguson's Essays. The chief difference between this and the original construction consists in the cap and stand being of brass instead of wood. He thus describes it:—

It consists of two stripes of gold leaf, *m*, *n*, suspended within a glass cylinder A B E D. This cylinder has a brass cap A B, a little broader than itself, in the centre of which is a hole, *a*, in the inside of the cap, which receives a small wedge of wood. On each side of this wedge, two equal stripes of gold leaf, free of all roughness at their edges, are fixed by a little varnish; these stripes are generally about two inches long, and about a quarter of an inch broad. The inside of the cap A B, and the upper part of the glass cylinder, are coated with sealing-wax. On the inside of the glass cylinder are pasted two slips of tin-foil, *b*, *c*, diametrically opposite to each other, and rising higher than the stripes of gold leaf. The lower ends of the tin-foil are in contact with the brass stand D E F, which supports the whole. For observing the electricity of the atmosphere, a pointed wire, C, is inserted in the brass cap A B. To use the electrometer, turn round the cap A B, till the surfaces of the gold leaf are parallel to the surfaces of the pieces of tin-foil *b*, *c*, so that the two stripes of gold leaf may hang in contact in the middle of the cylinder. Then, if a body containing a small quantity of electricity, be brought in contact with the cap A B, the gold leaves, *m*, *n*, will diverge, and their extremities will strike the slips of tin-foil *b*, *c*, and thus convey the electricity to the ground. See figs. 1 and 2, plate III.

154. There have been other improvements proposed on this electrometer, one of which was by Mr. Singer, and chiefly respects the mode of insulation. This instrument is represented in fig. 3: the following brief description of it will suffice to convey a correct idea of it. Like the preceding it is constructed with a glass cylinder, surmounted by a broad cap of either wood or metal. The insulation depends on a glass tube of four inches long, and one-fourth of an inch diameter, covered on both sides with sealing-wax, and having a brass wire of a sixteenth or twelfth of an inch thick, and five inches long, passing through its axis, so as to be perfectly free from contact with any part of the tube, in the middle of which it is fixed by a plug of silk, which keeps it in a concentric position with the internal diameter of the tube. A brass cap is screwed upon the upper part of this wire; it serves to limit the atmosphere from free contact with the outside of the tube, and at the same time to defend its inside from dust. To the lower part of the wire the gold leaves are fastened. The glass tube passes through the centre of the cap of the electrometer, and is cemented there about the middle of its length. When this construction is considered, it will be evident that the insulation of the wire, and also of the gold leaves, will be preserved until the inside as well as the outside of the glass tube become coated with moisture; but so effectually does the arrangement preclude this, that some of these electrometers have remained for seven years without being either warmed or wiped, and have still appeared to retain the same insulating power as at first. No. 2 shows this electrometer complete.

155. An electrometer of common use in the administration of medical electricity, sometimes attached to the Leyden jar, and sometimes made to fit into one of the ends of the prime conductor, is termed Lane's electrometer. Fig. 4 is a representation of this electrometer: it consists of two brass balls of equal size, one of which is connected with the inside coating of the jar, and the other insulated opposite to the first, yet so as to admit of its being placed in contact with it, or at any required distance from it. That which is insulated is connected by a wire with the outer coating of the jar, so as to serve as a course for the discharge which, it is very obvious from an inspection of the figure, will take place sooner or

later, according as the balls are placed either nearer to, or farther from, each other. But before we proceed to notice the *discharging* electrometer, we must describe one or two others which are both ingenious and useful.

156. We have described Mr. Cavallo's pocket electrometer at No. 154, but this gentleman constructed another portable electrometer for atmospherical purposes, which deserves particular notice. Its principal part consists of a glass tube C D M N, fig. 5, cemented at the bottom into the brass piece A B, by which part the instrument is to be held when used for the atmosphere; it also serves to screw the instrument into its brass case, A C, fig. 6. The upper part of the tube, C D M N, is tapered to a small extremity, which is entirely covered with sealing-wax; to this tapering part a small tube is cemented; the lower extremity being also covered with sealing-wax, projects a short way within the tube C D M N; into this smaller tube a wire is cemented, which with its under extremity touches the flat piece of ivory H, fastened to the tube by means of a cork; the upper extremity of the wire projects about a quarter of an inch above the tube, and screws into the brass cap E F, which cap is open at the bottom, and serves to defend the waxed part of the instrument from the rain, &c.

157. A section of the brass cap is represented in fig. 7, to show its internal structure, with the manner in which it is screwed to the wire projecting above the small tube L. This small tube and the upper extremity of the large tube, C D M N, appear like one continued piece when joined, from the sealing-wax covering them both. The conical corks, P, fig. 5, which show the electricity by their repulsion, are made very small, and suspended by very fine silver wires, shaped like rings at the top, by which they hang very loosely on the flat piece of ivory H, which has two holes in it. By this method of suspension, which Mr. Cavallo says is applicable to every sort of electrometer, the friction is reduced *to almost nothing, and the instrument is thus rendered sensible to a very small degree of electricity. I M and K N are two narrow slips of tin-foil, fixed on the inside of the glass C D M N,* and communicating with the brass bottom A B. They serve to convey that electricity which, when the balls touch the glass, is communicated to it, and, being accumulated, might disturb the free motion of the balls.

158. To use this instrument for artificial electricity, affect the brass cap E F, by an electrified substance, and the divergence or convergence of the balls of the electrometer, at the approach of an excited electric, will show the quality of the electricity. The best manner to electrify this instrument is, to bring excited wax so near the cap, that one or both of the corks may touch the side of the bottle C D M N, after which they will soon collapse and appear unelectrified. On removing the wax, they will again diverge, and remain electrified positively.

159. To try the electricity of the fogs, air, clouds, &c., by this electrometer, the electrician must unscrew it from its case, and hold it by the bottom A B, to present it to the air a little above his head, so that he may conveniently see the balls P, which will immediately diverge if there is any electricity; i.e. whether positive or negative may be ascertained, by bringing an excited piece of sealing-wax, or other electric, towards the cap E F.

160. M. Saussure has made an improvement in this electrometer. The principal circumstances in which his electrometer differs from Mr. Cavallo's, are: The fine wires, by which the balls are suspended, should not be so long as to reach the tin-foil which is pasted on the inside of the glass; because the electricity, when strong will cause them to touch this tin-foil twice consecutively, and thus deprive them in a moment of this electricity. To prevent this defect, and yet give them a sufficient degree of motion, it is necessary to use larger glasses than those that are generally applied to Mr. Cavallo's electrometer two or three inches diameter will answer the purpose very well. But, as it is necessary to carry off the electricity, which may be communicated to the inside of the glass, and may thus be confounded with that which belongs to those substances that are under examination, four pieces of tin-foil should be pasted on the inside of the glass; the balls should not be more than $\frac{1}{20}$ of an inch diameter, suspended by silver wires, moving freely in holes nicely rounded. The bottom of the electrometer should be of brass; for this renders it more easy to deprive them of any acquired electricity, by touching the bottom and top at the same time.

161. This electrometer may be used instead of the condenser of M. Volta, by only placing it on a piece of oiled silk, a little larger than the base of the instrument: but in this case the base and not the top, of the instrument must be brought in contact with the substance, the electricity of which is to be explored. By this instrument it is easy to ascertain the degree of conducting power in any substance. If it is placed on an imperfect conductor, as dry wood or marble, and if the instrument is electrified *strongly, and afterwards the top is touched, the electricity will appear to be destroyed; but, on lifting up the instrument by the top, the balls will again diverge,* because the imperfect conductor formed with the base a kind of electrophorus, by which the electric fluid was condensed, and lost its tension, till the perfect conductor was separated from the imperfect one; whereas, if the conductor had been more perfect, it would have been deprived of its electricity immediately on the application of the hand. It is useful to discover also the electricity of any substance, as of clothes, hair of different animals, &c. For this purpose it must be held by the base, and the substance rubbed briskly (only once) by the base of the electrometer; the kind of electricity may be ascertained in the usual manner. But as the top of the electrometer acts, in this case, as an insulated rubber, the electricity it acquires is always contrary to that of the rubbed body.

162. To collect a great quantity of electricity from the air, this electrometer is furnished with a pointed wire from fifteen inches to two feet long, which unscrews in three or four pieces, to render the instrument more portable, see fig. 8

When it rains or snows, the small cover, fig. 9, is to be screwed on the top of the instrument, as by this its insulation is preserved. This indicates not only the electricity of fogs, but also that of serene weather, and enables the observer to discover the kind of electricity which reigns in the atmosphere; and, in some degree, to form an estimate of its quantity, and that under two different points of view, the degree of intensity, and the distance from the earth at which it first begins to be sensible. A conductor exhibits signs of electricity only when the electric fluid is more or less condensed in the air than in the earth. Though the air resists the passage of the electric fluid, it is not absolutely impermeable to it; it suffers it to pass gradually, and generally with more ease in proportion as its mass is less. It is, therefore, interesting to discover at what height it is necessary to be elevated, in order to find a sensible difference between the electricity of the earth and that of the air.

163. Mr. Brooke of Norwich constructed an electrometer of a very ingenious description, and certainly valuable in its application, of which he has given a full account in his Miscellaneous Experiments; the limits, however, within which our article must be confined, will not allow of our giving his lengthened description of the instrument. We shall, therefore, present our readers with a short account of another electrometer, the invention of professor Robison of Edinburgh, which in our opinion is, in its chief essentials, much superior to that of Mr. Brooke. This beautiful and delicate instrument is represented by fig. 10, where A, a finely polished brass ball of a quarter of an inch diameter, is fixed on the point of a common sewing needle about three inches long, and as slender as can be procured of that length. On the other end of the needle is fixed a ball of amber, glass, or other non-conducting substance, of about ½ or ⅗ths of an inch in diameter. This ball is so fixed as that the needle does not quite reach to its surface, though the ball F must be completely perforated. From the electric ball there passes a slender glass rod, F, E, L, bent at right angles at E, so that *the part F E may be about three inches long, and the other extremity L, immediately opposite to* the centre of the ball A. A piece of amber C, so cut as to have two parallel cheeks, is fixed on the extremity L of the glass rod. For the principal part of the instrument, a strong dry silk thread is to be prepared by dipping it perpendicularly in melted sealing-wax, till it be fully penetrated by the wax, so as to retain a thin coating of it.

164. The thread, thus coated, must be kept extended, so that it may be quite straight; it must be made perfectly smooth by holding it before a fire, and rolling it on a smooth table. It is then to be passed through a small cube of amber, that has two holes drilled in two of its opposite faces, perpendicularly to the stalk. By these holes the cube is suspended, so as to move readily, on two fine brass pins, between the cheeks of the piece of amber at L. The waxed thread is about six inches long, and is equally divided by the amber cube. To the end B is fixed a ball of some conducting substance, as of polished metal, or gilt cork, a quarter of an inch in diameter. The other extremity D passes through a cork ball, so as to move with a slight friction.

165. The construction of this part of the electrometer is such that when F E lies perpendicularly to the horizon, and the stalk B D, with its balls, is allowed to hang freely, the ball B just touches the ball A, as represented in fig. 11. The ball F is fixed to one end of a glass rod F I passing perpendicularly through the centre of a graduated circle G H O, and furnished at the opposite extremity I with a knobbed handle of boxwood. H K is the stand of the electrometer, in the head of which is a hole in which the rod F I slides smoothly but not easily. There is also adapted to the glass rod F I an index N H that turns round it. This index is placed so as to be parallel to a line L A drawn through the centre of the ball A. And, as the circle is divided into 360 degrees, 0 being marked above, and 90 on the right hand; the index will point out the angle which the line L A makes with the vertical line. It is convenient to have another index on the rod F I turning with some friction round it, and extending considerably beyond the circle G H O.

166. When this electrometer is used for computing the quantum of electricity belonging to any body, it must be connected by means of a wire with the substance to be examined: the wire must be fixed into the hole of the ball F, which is in part filled by the needle; and indeed it must come in contact with the needle. The index must now be turned round by the handle I until it stand at 90°. In this position C B is horizontal, and the ball B contiguous to A. If in this position the balls B and A are electrified, they do not separate till the index be turned back towards 0. In some part of this space they will separate, and the point must be carefully noted, as this is the measure of their electric power while in contact. By turning still more towards 0, the separation is increased. An assistant must now turn the long index till it be parallel to the other, and consequently to C D. On loading the cork ball D with grain weights till B D be *nicely balanced in a horizontal position, and computing for the proportional length of C B and C D*, we obtain an exact measure in grains of the electric force with which the balls B and A separate in this position.

167. The electrometers already described have all been found highly useful to the practical electrician, according to the peculiar nature of the course of his experiments; but for ascertaining the actual repulsive and attractive powers of very faintly electrified bodies, they are perhaps all excelled by the ingenious invention of M. Coulomb, a French philosopher. The construction of this delicate instrument, which is called the *torsion balance*, will be best understood by a reference to the plate, where we have given a representation of it in its complete state, and of some of its parts on an enlarged scale.

Fig. 1, Plate IV., is a cylinder of flint glass twelve inches in diameter, and twelve in height, covered with a plate of glass, which is made to fit to it by a projecting fillet on the lower surface and having in it four round perforations, of

an inch and three-fourths in diameter, one of which is in the centre *f*, and receives the glass tube *fh*, which is two feet in height, and is fixed in the glass plate with cement. Into the top of this tube is inserted the brass piece H, fig. 2, No. 3, which is perfectly cylindrical, and having a small shoulder which rests on the top of the tube into which it is cemented. This brass piece is made to fit by means of a screw on the hollow cylinder, No. 2, fig. 2, to which is joined the circular plate *ab*, divided into 360 degrees, and having a hole G in its centre for admitting the cylindrical pin *i*, No. 1, fig. 2. This pin is surmounted with a milled head *b*, from which an index *io* projects, having a point turned downwards at *o*, to mark the divisions on *ab*. This pin moves with some friction in the hole G, while the cylinder moves steadily in the brass piece H. To the lower end of the pin there is attached the pincer *q*, resembling the end of a solid port crayon, and capable of being tightened by a sliding ring: so as to seize a fine silver wire, while its lower end is held by a similar pincer, shown by P*o*, fig. 3, and tightened by the sliding ring *r*.

168. The stalk *ro* is cylindrical, and is made so heavy as to keep the wire quite straig[illegible], without breaking it. Fig. 3 exhibits this pincer with the arm *z*C*q* passing through it. The length of this arm is eight inches, and it is formed of a stout silk thread, or a fine round straw coated with wax, or with lac; it is about one-tenth of an inch diameter, and six inches long, and is terminated by two inches of wax drawn out into a fine thread. The end *q* carries a pith-ball *a* turned very smooth, and gilded, and the other end is a small circular plane of paper covered with varnish, and of sufficient weight to counterpoise the pith-ball *a*, which is from one-fourth to one-half of an inch in diameter.

169. Fig. 1 represents the whole of the parts of the instrument in their combined form. The arm is represented as hanging horizontally in the middle of the glass cylinder, so as to admit of its turning freely round its centre, in a circle described on the glass by a graduated slip of paper divided into 360°. When *a* is opposite to *o* on this graduated circle it is contiguous to the ball *b*, which hangs within the cylinder by a silk thread covered with lac, and kept steady by the piece of wood, which is seen lying on the cover, from which it is suspended. Th[illegible]n of the instrument is produced by turning the milled head *b*, which carries the index *io*, called the *twist index*, round until it points to *o* on the graduated circle *ab*, and the whole is then turned in the brass socket H, till the ball *a* stands at O on the graduated paper circle Q. Fig. 4 represents a cylindrical stick of sealing-wax in the one end of which is inserted a fine brass wire terminated by a smooth ball. Fig. 5 is another part of this apparatus shown on an enlarged scale: it consists of a plug of sealing-wax A, which is made to fit tightly into the upper part of the instrument; through this plug of wax a wire *c*, hooked at the top, passes perpendicularly, and terminates in the finely polished metallic ball *d*; its use is to connect the electrometer with other bodies.

170. We shall here add, as an illustration of the method of using this ingenious instrument, an account of Coulomb's method of determining by it the electrical repulsion of the two balls *a* and *b* when electricity was communicated to them. Having electrified the brass pin, fig. 5, it was introduced through the hole *m*, in the top of the cylinder, and made to touch the ball *b*, in contact with the ball *a*, thus communicating its electricity to the two balls, which consequently became electrified with the same electricity; and, on this pin being withdrawn, a mutual repulsion took place between the two balls, *a* being driven from *b* to a distance easily measured on the graduated scale, and obviously regulated by the resistance of the wire to farther torsion. After a few slight oscillations the arm will rest and the degree of repulsion may be accurately noted. The index *io* is now to be turned backwards till the ball *a* come to its former position, by which movement the silver wire will be twisted, and a force produced proportional to the angle of torsion which is required to bring the ball *a* in contact with the ball *b*. By this means M. Coulomb ascertained the distance at which different angles of torsion bring the balls in contact after mutual repulsion; by comparing the forces of torsion with the corresponding distances of the balls, he obtained a measure of their repulsive force.

171. The following are given by Dr. D. Brewster, as the results of some experiments with this curious instrument, by its inventor.

(1.) The two balls being electrified with the head of the pin, and the index of the micrometer being set to zero, the ball *a* was repelled by the ball *b* to the distance of 36°.

(2.) The silver wire being twisted by turning the index of the micrometer 126°, the ball *a* approached to the ball *b*, and stopped at the distance of 18° from it, having moved backwards through an arc of 18°.

(3.) Having again twisted the silver wire through an arc of 567°, the two balls approached, and stopped at the distance of 8° 30′.

172. Now, as the force of torsion, or the force which is capable of keeping a thread twisted to a certain degree, so as to hinder it from turning round its axis, and recovering its natural state, has been shown by Coulomb to be proportional to the angle of torsion, or the arc through which it has been twisted, we have in the first experiment such a force, equal to 36°; and in the second experiment, when the distance of the balls was 18°, the angle, and consequently the force of torsion, was $126° + 18 = 144°$; hence the repulsive force, at the distance of 36°, was 36°: and the repulsive force, at the distance of 18°, was 144°, or quadruple at half the distance. In the third experiment, when the distance of the balls was 8° 30′, the force of torsion was 567°; so that, at a quarter of the distance, the repulsive force was nearly eight times as great. From this it follows, that the repulsive force of two small globes electrified either positively or negatively, is in the inverse ratio of the squares of the distance of the centres of the two globes.

173. In these experiments, the wire P*l* was twenty-eight inches long, and $\frac{1}{16}$ of a grain in weight,

and the force necessary to twist it through an angle of 300°, when at the distance *a* P, was $\frac{1}{130}$ of a grain, as calculated from the formulæ given by M. Coulomb in his Memoir on the force of Torsion. Hence the real forces in the preceding experiments were,

| Distances of the Balls. | Angles and Forces of Torsion. | Absolute Forces in grains. |
|---|---|---|
| 36° | 36 | $\frac{1}{3400}$th of a grain. |
| 18 | 144 | $\frac{1}{850}$ |
| $8\frac{1}{2}$ | 576 | $\frac{1}{212}$ |

174. An electrometer has been constructed by Mr. Cuthbertson, which, we think, in point of real utility, to the practical electrician, is equalled by none with which we are acquainted. Those only who have to go through the operation of melting wires before a public audience, can duly appreciate the value of this incomparable instrument. We have given in fig. 6 a representation of this discharging compound electrometer, as connected with a single jar, which, if it be about six inches in diameter and twelve inches high, will be sufficient to fuse four inches of fine pendulum wire. A description of it may be of use to the inexperienced electrician. The base G H is an oblong square piece of mahogany of about eighteen inches long, and six in breadth: in this are three glass supports, D, E, F, mounted with brass balls, *a*, *b*, *c*. Under the brass ball *a* there is placed a brass hook; the ball *c* is made of two hemispheres, the under one being fixed to the brass mounting, and the upper turned with a groove to shut upon it, so that it may be taken off at pleasure. The ball *b* has a brass tube fixed to it, about three inches long, cemented to the top of F; and a hole at the top, of about half an inch in diameter, corresponding with the inside of the tube. A B is a straight brass wire, with a knife-edged centre in the middle, placed a little below the centre of gravity, and equally balanced with a hollow brass ball at each end, the centre, or axis, resting upon a properly formed piece of brass fixed in the inside of the ball *c*; that side of the hemisphere towards *c* is slit open, to permit the end *c* A of the balance to descend till it touches the ball *a*, and the upper hemisphere C is also so opened to permit the end *c* B to ascend; *i* is a weight of a certain number of grains, and made in the form of a pin with a broad head; the ball B has two holes, one at the top, and the other at the bottom; the upper hole is so wide as to let the head of the pin pass through it, but to stop at the under one, having its shank hanging freely in *b*; several such pins are made to each electrometer of different weights; *k* is a Henley's quadrant electrometer, and when in use it is screwed upon the top of *c*.

175. It is obvious, from the construction, that if the foot stand horizontally, and the ball B be made to touch *b*, it will remain in that position without the help of the weight *i*; and if it should receive a low charge, the two balls *b*, B, will repel each other; B will begin to ascend, and, on account of the centre of gravity being above the centre of motion, the ascension will continue till A rest upon *a*. If the balance be again set horizontally, and a pin *i*, of any small weight, be put into its place in B, it will cause B to rest upon *b*, with a pressure equal to that weight, so that more electricity must be communicated than formerly, before the balls will separate; and, as the weight in B is increased or diminished, a greater or less quantity of electricity will be required to effect a separation.

176. When this instrument is to be used with a jar, or battery, one end of a wire, L, must be inserted into the ball *b*, and the other end into a hole of any ball proceeding from the inside of a battery, or jar, as M; *k* must be screwed upon *c*, with its index towards A; the reason of this instrument being added, is to show, by the index continuing to rise, that the charge of the battery is increasing, because the other part of the electrometer does not act till the battery has received its required charge.

177. It was formerly observed that the uncoated part of a jar might be too dry to admit of its being highly charged: the following experiment will illustrate the truth of this, as well as show the use of the electrometer just described in fusing wires. Every thing being prepared, as represented in the figure, with the jar M annexed to the electrometer, which jar may contain 168 square inches of coating put into B, the pin marked 15, take two inches of watch pendulum wire, fix to each end a pair of small pincers, as is represented at G *m*, hook one end to *m*, and the other to the wire N, communicating with the outside of the jar; let the uncoated part of the jar be made very clean and dry; and let the prime conductor of the machine, or a wire proceeding from it, touch the wire L; if then the machine be put in motion, the jar and electrometer will be charged, as will be seen by the rising of the index *k*, and, when charged high enough, B will be repelled by *b*; A will descend and discharge the jar through the wire, which was confined in the pincers, and the wire will be fused and run into globules.

178. Repeat this experiment with the following variations, viz. instead of two inches of wire take eight; and instead of loading the ball with fifteen, insert the pin weighing thirty grains; charge, as before, and a spontaneous explosion will take place between the coatings of the jar without moving the electrometer, and consequently the wire will remain as it was. But let the uncoated part of the jar be now a little moistened by breathing on it through a glass tube; charge the jar again, the electrometer will operate, the charge pass through the circuit, and the whole length of the wire will appear red-hot, and be instantly fused into globules.

179. A very useful instrument, called the universal discharger, was invented by Mr. Henley. It is shown in fig. 7, and consists of a mahogany base, A A, fourteen inches long, and about four broad. B, B, are two glass pillars, cemented in two holes upon the board A, and furnished at top with brass caps, each of which has a turning joint, and supports a spring tube, through which the wires D, D, slide. Each of the caps is composed of three pieces of brass, connected so that the wires D, D, besides their sliding through the sockets, have a horizontal and vertical motion. Each of the wires, D, D, is furnished with an

open ring at one end, and at the other it has a brass ball, which, by a short spring socket, is slipped upon the pointed extremity, and may be removed. E is a circular piece of wood, having on its surface a slip of ivory, inlaid, and furnished with a foot, which slides into the socket F, in which it is made fast at any required height by the screw S. To this discharger belongs the small press, fig. 8, the stem of which fits into the socket, instead of the circular table E. On the top of the stem are two oblong boards, which are pressed together by means of two screws. Between these boards may be placed any substance which requires to be pressed while the electric fluid is sent through it. The construction of this instrument is such as to enable the operator to use it with advantage in numerous experiments; particularly the oxidation of metallic leaves between slips of card paper, or of glass; splitting small pieces of oak, firing gunpowder, &c.

### Condensers and Doublers of Electricity.

180. Condensers of electricity are instruments used for the detection of very small portions of that matter, portions too minute to be rendered sensible by any of the electrometers which we have yet described. Several very ingenious electricians have employed themselves in the construction of instruments for this purpose: the principal of these contrivances we shall now briefly describe.

181. Volta appears to have been the first who attempted any thing of this description. His condenser of electricity consists of a flat and smooth metal plate, furnished with an insulating handle, and a semi-conducting, or imperfectly insulating, plane. When it is required to examine a weak electricity with this apparatus, as that of the air in calm and hot weather, which is not generally sensible to an electrometer, the operator must place the above-mentioned plate upon the semi-conducting plane, and a wire of some other conducting substance must be connected with the metal plate, and extended in the open air, so as to absorb its electricity; then, after a certain time, the metal plate must be separated from the plane; and, on being presented to an electrometer, it will electrify it much more than if it had not been placed upon the above-mentioned plane.

182. The principle on which the action of this apparatus depends, says Mr. Cavallo, is, that the metal plate, whilst standing contiguous to the semi-conducting plane, will both absorb and retain a much greater quantity of electricity than it can either absorb or retain when separate, its capacity being increased in the former and diminished in the latter case.

182.* This condenser was afterwards improved on by Mr. Cavallo, by employing a small metallic plate, about the size of a shilling, having affixed to it a glass handle covered with sealing-wax. When the larger plate appeared so slightly electrified by the communicated electricity as not to affect the electrometer, he then placed the small plate on the plane and touched it with the edge of the large one, holding the latter in an almost vertical position; the small plate was thus found to indicate a very sensible degree of electricity.

183. One of the most convenient and elegant condensers yet contrived is that of Mr. Cuthbertson. This instrument is shown in fig. 9, and is composed of two metallic plates, *a* and *b*, about six inches in diameter, tightly screwed to two brass balls, but so as that one of them be fixed immoveably to a glass pillar, as *e*, while the other is fastened to a brass pillar *f*, having a hinge at its lower extremity by which it can be moved backwards into the position *g*. When the instrument is used, the electricity to be examined is communicated to the insulated plate *b*, while it is parallel to the uninsulated plate *a*, and after remaining for some time in this position the uninsulated plate is drawn back, and the intensity of the insulated plate, *a*, is shown by being presented to an electrometer in the usual way.

184. A modification of this instrument, called the condensing electrometer, is represented by fig. 10. In this construction the plates are smaller, and the insulated plate is attached to the cap of a gold-leaf electrometer; by this means very small degrees of electricity are discovered, and their intensity shown by the divergence of the gold leaves within the cylinder.

185. A condenser, of a remarkably simple description was proposed by Mr. Singer, and is constructed by placing three small spots of sealing-wax, at equal distances, on the lower face of the cover of an electrophorus, to serve as insulating feet, by which the cover may be supported at the distance of about the twelfth of an inch from the surface of a smooth and even table. If a Leyden jar, he adds, be now charged, and afterwards discharged, so as not to affect an electrometer, and its knob be then placed in contact with the condenser resting on the table for a few seconds, the small residuum of electricity in the jar will be absorbed by the condensing plate; and when this is raised from the table it will affect the electrometer with the same electricity as that with which the jar was charged.

185*. Doublers of electricity are instruments so constructed as that very small quantities of electricity may be continually doubled by them, until, being condensed, they are rendered perceptible by the common electrometer.

186. An instrument of this kind was invented by the Rev. Mr. Bennet, and is represented by fig. 1, plate V. It is formed by the addition of two polished brass plates, with insulating handles, to the common gold-leaf electrometer. The plates are varnished on the lower side, and the insulating handle of one of them, B, is fixed to the side, while that of the other, A, is placed perpendicularly in the centre. Though this apparatus appears to be very simple, it requires a very complex process, and has, therefore, generally given place to what are called moveable or revolving doublers.

187. Revolving doublers appear to have been first introduced by Dr. Darwin, who claims the merit of the invention. Darwin's doubler was moved by a train of wheels, and required to be touched by the hand to place the plates in the requisite positions. This instrument was much improved by Mr. Nicholson; a representation of

it, in its improved form, is given in fig. 2. The whole is supported on a glass pillar six inches and a half high, and consisting of the following parts :—Two fixed plates of brass, A and C, are separately insulated and disposed in the same plane, so that a revolving plate B may pass very near them without touching. Each of these plates is two inches in diameter; they have adjusting pieces behind, which serve to place them correctly in the required position. D is a brass ball on which they turn, of two inches diameter, fixed on the extremity of an axis that carries the plate B. Besides the essential purpose which this ball is intended to answer, it is so loaded within on one side, that it serves as a counterpoise to the revolving plate, and enables the axis to remain at rest in any position.

188. The use of this ingenious instrument will be best understood from the following account of it given by Mr. Nicholson in the Philosophical Transactions :—'When the plates A and B,' says Mr. Nicholson, 'are opposite to each other, the two fixed plates A and C may be considered as one mass; and the revolving plate B, together with the ball D, will then constitute another mass. All the experiments yet made concur to prove that these two masses will not possess the same electric state; but that, with respect to each other, their electricities will be plus and minus. These plates would be simple, and without any compensation, if the masses were remote from each other; but, as that is not the case, a part of the redundant electricity will assume the form of a charge in the opposed plates A and B. From other experiments I find,' says Mr. Nicholson, 'that the effect of the compensation on plates opposed to each other at the distance of one-fortieth part of an inch, is such, that they require to produce a given intensity at least 100 times the quantity of electricity that would have produced it in either, if placed singly and apart.

189. The redundant electricities in the masses under consideration, will therefore be unequally distributed : the plate A will have about ninety-nine parts, and the plate C one; and, for the same reason, the revolving plate B will have ninety-nine parts of the opposite electricity, and the ball D one. The rotation, by destroying the contacts, preserves this unequal distribution, and carries B from A to C, at the same time that the tail K connects the ball with the plate C. In this situation, the electricity in B acts upon that in C, and produces the contrary state, by the communication between C and the ball; which must therefore acquire an electricity of the same kind with that of the revolving plate. But the rotation again destroys the contact, and restores B to its first situation opposite to A.'

190. Here, if we attend to the effect of the whole revolution, we shall find that the electric states of the respective masses have been greatly increased; for the ninety-nine parts in A and in B remain, and the one part of electricity in C has been increased so as nearly to compensate ninety-nine parts of the opposite electricity in the revolving plate B, while the communication produced an equal mutation in the electricity of the ball. A second rotation will of course produce a proportional augmentation of these increased quantities, and a continuance of turning will soon bring the intensities to their maximum, which is limited by an explosion between the plates.'

191. 'If one of the parts be connected with an electrometer, more especially that of Bennet, these effects will be very clearly seen. The spark is usually produced by a number of turns between eleven and twenty; and the electrometer is sensibly acted upon by still fewer. When one of the parts is occasionally connected with the earth, or when the adjustment of the plates is altered, there are some variations in the effects not difficult to be reduced to the general principles, but sufficiently curious to excite the attention of persons the most experienced in this branch of natural philosophy.

192. 'If the ball be connected with the lower part of Bennet's electrometer, and the plate A with the upper part, and any weak electricity be communicated to the electrometer, while the position of the apparatus is such that the cross piece G H touches the two pins, a very few turns will render it perceptible. But here, as in the common doubler, the effect is rendered uncertain by the condition that the communicated electricity must be strong enough to destroy and predominate over any other electricity which the plates may possess. I need scarcely observe, that, if this difficulty should be hereafter removed, the instrument will have great advantages as a multiplier of electricity in the facility of its use, the very speedy manner of its operation, and the unequivocal nature of its results.'

### The Electrophorus.

193. Several of the instruments we have now described appear capable of collecting and imparting small quantities of electricity; but it may be questioned if any of them can be said to do so on a scale comparable with that of the common electrophorus of Volta, which may be said to be a kind of electrical machine. Fig. 3 is a representation of this simple but highly useful article of apparatus, which any person at all skilled in the use of electrical apparatus may construct for himself by attending to the following directions. Procure two circular plates of metal, or of wood covered with tin-foil, and well rounded at the edges; these are the conductors: between them is placed a resinous plate, formed by melting together equal parts of shell-lac, resin, and Venice turpentine, and pouring this mixture, whilst fluid, within a tin hoop of the required size, placed on a marble table, from which the plate may be readily separated when cold. This plate should be half an inch in thickness; it is sometimes made by pouring the mixture on one of the conductors, which is then formed with a rim for that purpose. In the centre of the upper conductor is fixed a glass handle of about ten inches long, for the purpose of lifting it without drawing off its electricity; and, when the electric state of the lower conductor is to be examined, the whole apparatus must be placed on an insulating stand. To use the electrophorus, rub the upper surface of the resinous plate with a piece of dry fur; cat's skin is

reckoned the best, and it will be excited negatively. Place the upper conductor upon it, and then raise the same by its insulating handle; it will be found to exhibit very faint, if any, electrical signs. Replace the conductor, and, whilst it lies on the surface of the excited plate, touch it with a finger or any other uninsulated conductor, and then raise it again by its handle. It will now be positively electrified, and afford a spark: if it be then replaced on the resinous plate, touched, and again raised, another spark will be procured, and this process may be repeated for a considerable time without any perceptible diminution of effect. Jars may be charged by bringing them in contact with the conductor each time it is lifted, with an instrument of this kind only six inches in diameter. Cavallo charged a jar several times successively, and such was the strength of the charge that it was capable of piercing a card.

194. Such is the tenacity, so to speak, with which this instrument holds the electricity once excited, that some have been led to consider it as affording a perpetual source of that matter. On this opinion Mr. Cavallo makes the following just remarks:—'As to the continuance of this electric plate, when once excited without repeating the excitation, I think there is not the least foundation for believing it perpetual, as some gentlemen have supposed it to be; it being nothing more than an excited electric, it must gradually lose its power, by continually imparting some of its electricity to the air, or other substances contiguous to it. Indeed its electricity, although it could never be proved to be perpetual by experiments, lasts a very long time, it having been observed to be pretty strong several days, and even weeks, after excitation. The great duration of the electricity of this plate, I think, depends upon two causes: first, because it does not lose any electricity by the operation of putting the metal plate upon it, &c.; and, secondly, because of its flat figure, which exposes it to a less quantity of air, in comparison with a stick of sealing-wax, or the like, which, being cylindrical exposes its surface to a greater quantity of air, which is continually robbing the excited electrics of their virtue.' Numerous experiments are given in the writings of electricians as having been performed by the aid of this instrument; these we shall not here detail, but simply remark, that, if properly managed, it will be found capable of communicating a very high charge to tolerably sized Leyden jars

## PART III.

### MECHANICAL EFFECTS OF ELECTRICITY.

195. Under this part of the subject it is intended to give a popular view of a variety of electrical phenomena rather of a general and promiscuous nature, and which, from the variety necessarily involved, could not have been conveniently introduced under any other head. Among others we shall notice chiefly the following, viz. the direction of the electric fluid; its influence in expanding bodies through which it is made to pass; its power in rending solid bodies; its agency in the combustion and oxidation of metallic substances, and in inflaming numerous combustible substances.

### Direction of the Electrical Fluid.

196. From among the numerous experiments given to demonstrate, as far as it can be done the course of the electric fluid in its passages from one body to another, we select the following from Mr. Singer and others.

197. The direction of the electric fluid may be rendered visible by taking a Leyden jar that has been rendered slightly damp by being breathed on, and placing it with its knob in contact with the positive conductor of an electrical machine in a darkened room; when the jar is fully charged, if the action of the machine be continued, the fluid will be observed to pass from the internal to the external coating over the uncoated interval in luminous streams, like water overflowing from the top of a vessel kept constantly supplied. If the jar be removed, and its knob placed against the negative conductor, the stream will evidently pass in the contrary direction. A degree of dampness on the uncoated part of the glass is necessary, in this experiment, to prevent the discharge of the jar by a spontaneous explosion, in which case the fluid passes too rapidly from one surface to the other to allow the observer to ascertain its direction. If the moisture be not sufficient, diverging brushes of light will occasionally pass from the positive surface, instead of the continuous streams above mentioned.

198. Let a light wheel, the vanes of which are made of fine card-paper, be made to turn freely on its axis, a stream of electricity from a pointed wire fixed in the conductor will give it motion; and it will move from the electrified point whether its electricity be positive or negative. In this experiment the current seems to be produced by the recession of the similarly electrified air in contact with the point; and, therefore, the circumstance of the wheel turning in the same direction when the electricity is negative, cannot, as Mr. Singer has justly observed, be considered as a proof of the existence of a double current of the electric fluid.

199. Make a groove, either by bending a piece of clean card-paper, or by hollowing out a piece of baked wood, or by placing, parallel to each other, two straight sticks of sealing-wax; lay the groove upon the plate of Henley's universal discharger, and place a large pith-ball, about half an inch in diameter, so as to be at an equal distance from the two brass knobs of the discharger. The distance of these should be about four inches, and the groove placed in the line joining the knobs. If one of the wires be now connected with the outside of a charged jar, while the knob of it is brought in contact with the other wire of the discharger, so that a small spark may pass from the one knob to the other, the pith-ball will be impelled from the positive to the negative knob. In performing the above experiment Mr. Singer used pointed wires instead of knobbed ones, and assigned, as his reason for this, that the knobs may attract the pith-ball, whereas the stream from the pointed wire must impel it.

200. Mr. Singer in the following experiment has availed himself of the discovery of Cavallo, who observed that some mineral colors are affected by passing over them the electrical discharge. Color, says he, both sides of a card with vermilion, and place it upon the table of Henley's discharger; one of the wires should be beneath the card, and the other in contact with its upper surface; the distance of the points of the wires being one inch. If a charge be now sent through the wires, the fluid will pass from the positive wire across the surface of the card to the part over the negative wire, and will there perforate the card in its passage to that wire. The course of the fluid is indicated by a black line on the card, reaching from the point of the positive wire to the perforation; and by a diffused black mark on the opposite side of the card around it, and next the negative wire. These effects are pretty constant, the black line always appearing on the side of the card which is in contact with the positive wire, and the perforation being near the negative wire.

201. But the most satisfactory exhibition of the course of the fluid from the positive to the negative conductor is afforded in the next experiment, which was the contrivance of Mr. Singer, and which he himself considered as removing all difficulties on the subject. It has, observes he, been long known that a light float-wheel, made by inserting several vanes of card in the periphery of a cork that is made to turn freely on a pin or centre, will be put in motion by presenting it to an electrified point; and the motion of the wheel being always from the point, whether that point was positive or negative, has been occasionally urged as an argument for a double current of the fluid; although it is evident, from what has been already stated, that a point either positive or negative must produce a current, by the recession of the air opposed to it when similarly electrified, by its contact, which is fully adequate to the production of these effects. Conjecturing that the currents of electrified air would not take place in this manner if the points were opposed to each other, the following arrangement was made.

202. A light float-wheel of the above description, being mounted so as to turn freely between two upright wires, was placed on an insulated stem, and introduced between the pointed wires of Henley's discharger, which were placed accurately opposite to each other, and at the distance of rather better than an inch from the upper vanes of their respective sides. On connecting one of the wires with the positive conductor of the machine, and the other with the negative conductor, and turning the machine, the wheel will move in a direction from the positive to the negative wire. On reversing the connexions, so that the wire which was negative may become positive, and that which was positive be made negative the motion of the wheel will be reversed; for it will still move from the positive to the negative wire, thus proving that the electricity moves in that direction. A representation of this wheel, with the method of using it, is given in fig. 3, where A is the float-wheel placed on the universal discharger B, the wires of which, C, C, are directed against the floats of the wheel.

### Expansive Power of the Fluid.

203. The influence of the electric matter in expanding bodies through which it is sent, may be clearly illustrated by these experiments. Place a small card, or the cover of a book, against the outer coating of a charged jar, exposing about a square foot of coated surface; put one end of the discharging rod against the card, and bring the other to the knob of the jar; the charge will pass through the card and perforate it, producing a small bur on the side next the discharging rod, and a larger one on the side which was in contact with the coating of the jar. In the same manner, by using the more powerful charge of a battery, a perforation may be made through a quire of paper or a thin unbound book; and, if either of these be freely suspended between the balls of the universal discharger, no motion of the paper will be produced, but the charge will pass through it without in the least disturbing it, for the same reason that a musket ball will pass through a door without causing it to turn on its hinges, although, under the same circumstances, a very slight force would be sufficient to move it.

204. The effects produced on the card in the preceding experiment, as well as some others that have resulted when the experiment has been varied, have led some electricians to suppose that they might be viewed as indications of the course of the electric matter, and as affording no obscure proof of the existence of two fluids; but Mr. Singer has, in our opinion, satisfactorily shown that they are produced solely by an expansion of the paper.

205. The following illustration of this influence is attributed to Mr. Lane, the inventor of the discharging electrometer. Roll up a piece of soft pipe-clay, in the form of a small cylinder, and insert in it two wires, so that their ends, without the clay, may be about one-fifth of an inch from one another. If a charge be sent through this clay, by connecting one of the wires with the outside of a jar, and the other with the inside, it will be inflated by the shock passing between the two wires, and, after the explosion, will appear swelled in the middle. If the charge sent through it is too strong, and the clay not very moist, it will be broken by the explosion, and the fragments scattered in every direction. To make this experiment with a little variation, take a piece of the tube of a tobacco-pipe, about one inch long, and fill its bore with moist clay; then insert in it two wires, as in the above rolled clay, and send a charge through it. This tube will be burst by the force of the explosion, and its fragments will be scattered about to a great distance. If, instead of clay, the above-mentioned tube of the tobacco-pipe, or a glass tube, which will answer as well, be filled with any other substance, either electric or non-electric, inferior to metal, on making the discharge it will be broken to pieces with nearly the same force.

206. The expansion of fluids by electricity is truly remarkable, and often productive of some singular results. When the charge is strong, no

glass vessel can resist its force. Beccaria placed a drop of water between two wires in the centre of a solid glass ball of two inches in diameter; on passing a shock through the water the ball was dispersed with great violence. Mr. Morgan succeeded, by the same means, in breaking green glass bottles, filled with water, when the distance between the wires that conveyed the spark and the sides of the glass was upwards of two inches.

207. A single spark may be made to perforate a strong glass tube by the following simple process: fill a small phial with olive oil, and insert into it a pointed wire bent at right angles, so that by sliding through a cork fixed in the neck of the phial, the point of the wire may rest against any part of the inside beneath the oil: attach the phial by its wire to the conductor of the machine, and bring the knuckle or a brass ball near the outside of the phial, opposite to the point of the wire within it; a spark will pass from the point to the knuckle, and make a small hole in the glass. By varying the situation of the point, many such perforations may be made in the glass.

208. Of this very singular experiment Mr. Singer offers the following rational account. The point, he says, serves as an internal coating to a very small portion of the glass; and the charge being prevented from extending, by the surrounding oil, the whole power of the machine is concentrated in that point, and consequently soon overcomes its resistance. Similar effects will always result when a large quantity of electricity is suddenly transferred to a comparatively limited surface.

209. Make a small mortar of ivory, with a cavity of half an inch diameter and an inch deep; insert two wires through the sides of the mortar, so that their points within the cavity may be separated by an interval of $\frac{1}{4}$ of an inch; fit a cork cap so as to close the aperture as accurately as possible without friction: when a strong charge is passed through the wires, the air within the mortar will be suddenly expanded, and the cork projected to a distance with some violence.

210. Satisfactory and striking as the preceding experiments are, they appear inferior to the following: in making experiments on the effects of explosions of electricity sent through metallic bodies, Dr. Priestley found that a chain which he had used as the medium of conveying the charge was shorter after being used than it was before. This led him to try the effect of a strong charge on a definite length of chain: the charge was sent from sixty-four square feet of coated surface, through twenty-eight inches of chain, which, on being measured again, was found to be contracted a quarter of an inch in its whole length.

211. This experiment was repeated by Mr. Nairne with a piece of hard-drawn iron wire ten inches in length, and $\frac{1}{100}$ of an inch in diameter. Through this wire he discharged twenty-six feet of coated surface nine times; after the sixth and the ninth time the wire was measured, and it was found to be shortened $\frac{1}{10}$ of an inch after each discharge. By farther discharges sent through it, the wire was shortened $1\frac{1}{10}$th inch. That this contraction arose from expansion appeared from the wire having increased in thickness whilst it was diminished in length.

## Solid Bodies ruptured by Electricity.

212. The simplest form, perhaps, in which this can be done, is to place on the table of Henley's discharger a piece of dry writing-paper, and pass over it, by means of the pointed wires, a powerful charge from a large jar; if the wires be placed at about two inches asunder, and so as to touch the ends of the paper, it will be torn in pieces. If, instead of the paper, a number of wafers be placed in the circuit, they will be curiously dispersed, and many of them broken to pieces.

213. Make two small holes in the opposite ends of a piece of oak, of about half an inch long and a quarter of an inch thick; introduce two wires into the holes, so that their extremities within the wood may be rather less than a quarter of an inch distant; on passing a strong charge from one wire to another, the wood will be split. Several other substances that are imperfect conductors, such as loaf-sugar, marble, &c., undergo similar injuries, when introduced into an electrical circuit; and even the hardest bodies, and the most perfect non-conductors, such as glass, are perforated or broken by a strong charge.

214. Lay a piece of plate-glass of about an inch square, and half an inch thick, on the table of the universal discharger, or screw it very tightly within the press of the same; set the prints of the sliding wires opposite to each other, and against the under surface of the glass, so that the charge may pass along that surface. If now a strong charge be passed in this way, the glass will be broken into small fragments, and some of it reduced to an impalpable powder.

215. The following experiment affords a beautiful, though rather an expensive, illustration of the same principle. Charge a very large jar, and connect its external coating with that of one ten or twelve times smaller; form a communication between their internal coatings by the discharging rod, and the small jar will be broken in pieces, by the strength of the quantity of electricity thus suddenly transferred to it.

## Inflammable Substances Kindled by Electricity.

216. Almost all inflammable substances may be kindled by means of electricity, but those generally selected for the purpose of experiment are resin, gunpowder, rectified spirit of wine, ether, and hydrogen gas.

217. The common method of kindling resin by the electric spark is to pulverise it, and dust the powder on some dry cotton wool. Thus, if a small quantity of flax, or of cotton wool, be loosely tied on one of the knobs of the discharging rod, and a little finely-powdered resin dusted on it, and a jar be discharged by bringing the end of the rod thus prepared in contact with the knob of the jar, the charge will pass through the flax, or wool, and in so doing will melt and ignite the resin, and set the whole on fire. A very neat contrivance for giving this experiment

a better effect is represented by fig. 4. A is a mahogany board, six inches in length, three in breadth, and half an inch in thickness. B is a glass pillar fixed in the middle of A, and supporting a piece of wood C, which is three inches long, an inch and a half broad, and about three quarters of an inch thick. In each end of this piece there is a small screw-ring: the extremities of these screws just touch a wire proceeding to each of them from two small brass knobs inserted at the ends of a shallow groove on the upper side of C; these rings serve to hook the chains on when the instrument is used. On the back part of C stands the perpendicular piece D, in the top of which is fixed the brass pin E. To use this for the purpose of igniting resin, it is only necessary to dust the cotton with powdered resin, and hang it on the pin E, letting the lower part of it reach down to the piece C. Connect one end of C with the inside of a jar and the other end with the outside; discharge the jar, and the fluid in passing between the two small brass knobs will inflame the resin and kindle the cotton.

218. But the inflammation of resin is rendered still more striking by the following experiment: let a flat porcelain dish be filled with water, and on the surface of the water strew a quantity of finely powdered resin; place two wires at the opposite sides of the dish, having their ends near the surface of the water, and at about the distance of four inches from each other. Pass the charge of a large jar through this circuit, and the resin which forms a part of it will be beautifully inflamed.

219. The firing of gunpowder by the electrical explosion requires considerably more care and address than the firing of resin. It may, however, be effected by the following method: take either a large goose-quill or a small cartridge of paper, and fill it with gunpowder ground very fine; into this insert two wires, one at each extremity, so that their ends within the quill or cartridge may be about one-fifth of an inch from each other: this done, send the charge of a phial through the wires; and the spark between their extremities, that are within the cartridge, or quill, will inflame the gunpowder. If the gunpowder be mixed with steel-filings, it will take fire more readily, and with a very small charge.

220. Rectified spirit of wine, or ether, may be thus inflamed by a single spark from the conductor of the machine when in action: hang to the prime conductor a short rod having a small knob at its end; then pour some spirit of wine, a little warmed, into a metallic spoon; hold the spoon by the handle, and place it so that the small knob on the rod may be about one inch above the surface of the spirit. In this situation, if a spark be taken from the knob, it will set the spirit on fire. This experiment may be varied and rendered very agreeable to a company of spectators. A person standing upon the insulating stool, and communicating with the prime conductor, may hold the spoon with the spirit in his hand, and another person standing upon the floor may set the spirit on fire by bringing his finger within a small distance of it. Instead of his finger, he may fire the spirit with a piece of ice, when the experiment will seem much more surprising. If the spoon is held by the person standing upon the floor, and the insulated person brings some conducting substance over the surface of the spirit, the experiment succeeds equally well. This experiment is sometimes rendered still more striking in the following manner: near the prime conductor of the machine, place on the table three wine glasses; connect the first glass with the conductor by a brass chain, which will reach to the bottom of it; and with it let the second and third be connected by a piece of fine brass wire, bent in the form of the letter A. Fill the first and second glasses with water, and into the third pour a little ether; turn the machine, and with a wire, having a small ball affixed to it, draw a spark from the ether, and it will be immediately inflamed. In this experiment the electric fluid had to pass through two distinct portions of water before it could come to the ether.

221. Hydrogen gas is generally inflamed by the electric spark in the following manner: take a brass cannon, such as is represented in fig. 5, and charge it with hydrogen gas by holding the mouth of it for about half a minute over a stone or glass bottle in which the gas is generated, and then fix the cork tightly into the mouth of the cannon. The person who is to discharge it must now stand on the insulating stool, and, holding in his hand a chain attached to the prime conductor, must, with a wire and ball held in the other hand, communicate a spark to the knob of the cannon: this spark will pass into the interior of the cannon through the glass tube B, and the gas will instantly explode with a loud report, and the cork will be driven out to a considerable distance. This experiment may be rendered more effectual by mixing about one-third of oxygen with the hydrogen gas; or, if oxygen cannot be conveniently procured at the time, the operator may easily contrive to have some atmospheric air in the cannon, which will render the hydrogen gas more explosive.

222. The very great ease with which inflammable air is kindled by even a small spark of electricity seems to have suggested to M. Volta the idea of what he calls his inflammable air-lamp, an instrument which appears to have laid the foundation for the patent apparatus for obtaining instantaneous light. This curious instrument is represented in fig. 6, where A is a glass globe for containing hydrogen gas; B a glass reservoir for holding water; and D a stop-cock, by which a communication is formed between the water and the gas. The water passes into the globe through the pipe *gg*, which is fixed into the top of the reservoir A; at *s* there is a cock to cut off or open a communication between the air and the jar K. N is a contrivance for holding a wax-taper; L a brass pillar, on the top of which is fixed a ball of the same metal; *a* is a pillar of glass, with a socket at the top, in which the wire *b* slides, having a ball screwed on the end of it. F is a cock by which the globe is filled with hydrogen gas, and which afterwards serves to confine it, and what water falls into B and A. To use this instrument,

having filled the globe with gas, and the reservoir A with water, turn the cocks D and *s*, and the water will fall into the globe, forcing up a quantity of gas, which will rise through the pipe K. If, now, an electric spark be made to pass from the ball *m* to that marked *n*, it will set fire to the gas which passes through the pipe K. To extinguish the lamp, first shut the cock *s*, and then D. The gas is obtained in the usual way, from diluted sulphuric acid and iron filings; and the globe is to be filled in the following manner:—Having previously filled it with water, place the foot R in a vessel of water, so that it may be covered, and the bent glass tube, through which the gas is to be introduced, may pass commodiously below the foot. When the gas has displaced nearly all the water, turn the cock F, and the lamp is ready for use.

223. This instrument is sometimes constructed so as to be connected with an electrophorus for the purpose of producing a light at pleasure. In this case the electrophorus is placed in a box beneath the vessel containing the hydrogen gas; from this box a wire passes through a glass tube to the opening of the stop-cock. The cover of the electrophorus must be connected by a silk string with the handle of the stop-cock, so that the same motion that opens the cock, may raise the cover of the electrophorus, and the spark that strikes from it be conveyed by the insulated wire to the stream of gas, which it inflames. This effect will take place every time the stop-cock is opened, for the electrophorus will produce sparks for a considerable time, without any fresh excitation; and the quantity of gas consumed at each repetition of the process is very small, so that a light may be obtained above a hundred times before the contents of the reservoir are expended; and it may then be easily replenished.

224. But by far the most remarkable effects of electricity in producing combustion, result from its action on metallic substances. This property of the electric matter seems to have been first observed by the celebrated Dr. Franklin, who made several experiments on the subject. These experiments were repeated and extended by Mr. Kinnersly, and also by Beccaria; and have since then been prosecuted with great accuracy by Mr. Brook, Dr. Van Marum, Mr. Cuthbertson, Mr. Singer, and others. In treating on this part of the subject, we shall, as in the preceding instances, give a course of progressive experiments, which may be made with an appropriate apparatus, from a single jar of a tolerably large size, up to a powerful battery, previously remarking that the whole of the apparatus must be in the very best state in which it can be put, otherwise disappointment, in many cases, and inaccuracy in all, will be the result.

225. The slightest indication of the fusing of metallic substances is observed in the discharge of the Leyden phial: on this occasion, if the discharge be made by means of the common discharging rod, the knob that touches the outside coating will be found to adhere slightly to the jar after the discharge; and this arises from the fusing of a small portion of the tin-foil coating.

226. This may be rendered very obvious by the following experiment:—Charge a large jar, and place a smooth piece of coin between the knob of the discharger and the coating of the jar; when the discharge has been made, the piece of coin will be found slightly adhering to the tin-foil, by its fusion at the point of contact, and will remain so as to require some force to separate them.

227. Dr. Franklin's experiments on the fusing of metals may be thus imitated:—Take three pieces of window-glass, each one inch wide, and three inches long, and place them contiguous to each other, with two narrow strips of gold-leaf between them, so that the middle glass may have, on each side of it, a strip of gold, with its ends projecting a little beyond the glass. Let the whole be properly secured within the press of the universal discharger; pass the charge of a large jar through the strips of gold, they will be melted and driven into the glass. The outer pieces of glass are generally broken, but the middle piece is often left entire, and is marked with an indelible metallic stain on each of its surfaces.

228. The colors produced when metals are thus fused, either on glass or paper, are sometimes exceedingly beautiful, and have been in some cases employed in impressing letters, and ornaments of various kinds, on silk and paper. The process observed in such cases, Mr. Singer thus describes in his Elements:—'The outline of the required figure is first traced on thick drawing paper, and afterwards cut out in the manner of stencil plates. The drawing paper is then placed on the silk or paper intended to be marked; a leaf of gold is laid upon it, and a card over that; the whole is then placed in a press, or under a weight, and a charge from a battery sent through the gold leaf. The stain is confined, by the interposition of the drawing paper, to the limit of the design; and in this way a profile, a flower, or any other outline figure may be very neatly impressed.'

229. In describing Cuthbertson's electrometer, No. 177, we made some remarks on the fusing of wire, by passing through it the discharge of accumulated electricity; it may be necessary to offer here some general observations on the same subject; and to give some account of the results of the experiments made by those whose names we have already enumerated.

230 For the fusing of wires of different lengths very large batteries were formerly considered as indispensable; but Mr. Singer observes, that, if the wire be sufficiently fine, a single jar, exposing a coated surface of about 190 square inches, will be sufficient to afford an example of the effect. The finest flattened steel wire, sold at the watchmakers' tool shops under the name of pendulum wire, is the best for the purpose; harpsichord wire not being fine enough, excepting where great power is used. Cuthbertson's Balance Electrometer should be invariably used to regulate the charge; the circuit made as short as possible; and the wire to be fused placed in a straight line, and held at the ends between a small forceps made of wire.

231. The following is the substance of Mr. Singer's remarks on the numerous experiments of Messrs. Brook and Cuthbertson on the fusion of metallic wires. Their conclusion was, that the action of electricity on wires increases in the ratio of the square of the increased power: since two jars, charged to any degree, will meet four times the length of wire that one jar will melt; and this will be again quadrupled by doubling the height of the charge.

232. This law, adds Mr. Singer, I have found, obtains in all accurate experiments with moderate lengths of wire; and it is apparent in Mr. Cuthbertson's experiments, to some extent. His batteries usually contain fifteen jars, and one of these is just sufficient to fuse half an inch of wire of $\frac{1}{150}$th of an inch diameter: but the whole fifteen jars combined, will fuse sixty inches of the same wire. Mr. Singer made some experiments with an iron wire of $\frac{1}{250}$th of an inch diameter, on an extensive scale; but he found that some of the charge was lost in pervading such a considerable length of wire, so much so, that the explosion of the battery, at other times remarkably loud, was then scarcely audible. With a battery, however, of forty feet of coated surface, Mr. Singer says he frequently melted eighteen feet of the above-mentioned wire by a single explosion, and the phenomena were remarkably brilliant; a shower of intensely ignited globules being dispersed in every direction. This law, however, Mr. Singer found to vary with the thickness of the glass employed; thick jars displaying the same intensity with a comparatively small quantity of electricity; and consequently having, as he expresses it, less wire-melting power. Of this he produces a proof, furnished by his large Leyden jar, to which we have already alluded; this jar, from the extent of its coated surface, ought to have melted three feet of wire, with a charge of thirty grains; but from its extreme thickness, which limited its electrical virtue, it would only melt eighteen inches. Mr. Singer remarks, that this is correspondent with the conclusion of M. Cavendish, that the quantities of electricity required to charge different coated jars of the same extent, will be in the inverse proportion of their thickness.

233. The fusion of wire may therefore be employed as a measure of the quantity of electricity accumulated on any charged surface; for the preceding experiments show that any given quantity of electricity will fuse the same length of wire, whether that surface be disposed on two jars or one; hence it may be inferred that the actual intensity of a charge does not materially affect its power in melting wire. This test is therefore practically useful; for the various electrometers measure only the intensity, and are as much affected by one jar as by a battery of 100. When the fusion of wire is employed as a test of electrical power, care should be taken that the length of the circuit be always the same, and that the degrees of ignition be uniform; for a wire may be melted with but slight variations of appearance when very different portions of electricity are passed through it. The lowest degree of perfect ignition ought therefore to be obtained in all comparative experiments; and, as soon as the discharge is made, the wire should become red-hot in its whole length, and then fall into fine globules.

234. The gradually increasing effects produced are very remarkable, when, on wires of the same length and diameter, progressively strong charges are transmitted. If the charge be very low, it is found that the color is changed to yellow; it then becomes blue by a higher charge; then red-hot; then red-hot and melted into balls; and, if we increase the charge still further, it becomes red-hot, and drops into balls, then disperses in a shower of balls, and finally disappears with a bright flash, producing an apparent smoke, which turns out when collected to be a fine powder, consisting of the metal combined with oxygen, and weighing more than the metal which was originally fused.

235. The experiments and results already enumerated do by no means form the boundary of the power of the electric fluid; bodies which resist the most intense heat, produced in the common way, are by it converted into oxides in a moment. Of this more will be said in a future part of this article; in the meantime a few examples may be given, which properly belong to the present. The most laborious experimenters on this part of electricity have been Cuthbertson and Singer, of whose operations we shall here avail ourselves, as being both numerous and valuable. The apparatus used by Mr. Cuthbertson, and, in some of his experiments, by Mr. Singer also, may be thus described:—

236. It consists of a glass cylinder *a b*, fig. 7, about eight inches high, and two inches and a half diameter, mounted air-tight with two brass caps. On the lower cap *a* is screwed a stop-cock, and above the cap is fixed a small roller, on which a quantity of wire, attached to a pack-thread at intervals of four inches, is coiled. A brass tube *c*, about three inches long, is screwed into the centre of the upper cap *b*, and, by means of a long needle, the end of the packthread and wire is thrust through it, and hog's lard is placed in the tube, so that the wire and packthread shall always move through it air-tight. In this way the wire is extended in the centre of the cylinder, and, when one length is exploded, another may be drawn forward by means of the packthread, without opening the cylinder. For ascertaining the quantity of air absorbed during the process, a gauge, represented by A, about ten inches long, made of a glass tube, is screwed into the lower end of the stop-cock, and immersed in a vessel of quicksilver, the rise of which, when the stop-cock is opened, will be a measure of the air absorbed. The air left in the receiver, after a number of explosions, is always found to have been deprived of a portion of its oxygen; and, if hydrogen or nitrogen gas be substituted in place of atmospheric air, the metal will not suffer any oxidation, but will be fused, and minutely divided.

237. To accomplish the complete oxidation of metallic substances, a higher power is required than that which is merely adequate to fuse them. The following is a statement of the comparative strength of the charges which Mr. Cuthbertson

employed in exploding the wires mentioned, the length of each wire being ten inches: the coated surface was the same in all the experiments, viz. one of his batteries of fifteen jars, exposing seventeen feet of coated surface. The column marked A, shows the diameter of the wires in parts of an inch; B the number of grains with which the electrometer was loaded; and C the color of the oxide deposited on the receiver:—

| | A. | B. | C. |
|---|---|---|---|
| Lead wire . . | $\frac{1}{90}$ . | 20 | . Light gray. |
| Tin wire . . | $\frac{1}{90}$ . | 30 | . Nearly white. |
| Zinc wire . . | $\frac{1}{90}$ . | 45 | . Nearly white. |
| Iron wire . . | $\frac{1}{150}$ . | 35 | . Reddish brown. |
| Copper wire . | $\frac{1}{150}$ . | 35 | . Purple brown. |
| Platina wire . | $\frac{1}{150}$ . | 35 | . Black. |
| Silver wire . . | $\frac{1}{150}$ . | 40 | . Black. |
| Gold wire - . | $\frac{1}{150}$ . | 40 | . Brownish purple |

238. Mr. Singer was of opinion that the charges here given by Mr. Cuthbertson were rather high, and attended with considerable risk of fracture to the jars: he repeated the experiments with shorter lengths of wire, and of less diameter; and with more moderate charges obtained the following results:—

| | A. | B. | C. |
|---|---|---|---|
| Gold wire | $\frac{1}{180}$ | 18 | Purple and [illegible]rown. |
| Silver wire | $\frac{1}{100}$ | 18 | Gray, brown, and green. |
| Platina wire | $\frac{1}{180}$ | 13 | Gray and light brown. |
| Copper wire | $\frac{1}{180}$ | 12 | Green, yellow, and brown. |
| Iron wire . | $\frac{1}{180}$ | 12 | Light brown. |
| Tin wire . | $\frac{1}{180}$ | 11 | Yellow and gray. |
| Zinc wire . | $\frac{1}{180}$ | 17 | Dark brown. |
| Lead wire . | $\frac{1}{180}$ | 10 | Brown and blue gray. |
| Brass wire . | $\frac{1}{180}$ | 12 | Purple and brown. |

239. In the above experiments Mr. Singer did not use the receiver; the wires, which were five inches in length, were stretched parallel to the surface of a sheet of paper, and distant from it about one-eighth of an inch. Brass wire is sometimes decomposed by the electrical charge, in which case its component parts, copper and zinc, are separated from each other, and appear in their distinct metallic colors when the explosion is made over a piece of glass. Indeed the figures of all the oxides are most beautiful when impressed on glass, although their colors are certainly less permanent.

240. This most amazing power of the electric matter is not only adequate to the oxidation of metallic substances, but is yet more remarkable in restoring oxides, already formed, to their metallic, or original state, for which purpose a very simple process will be found sufficient.

241. Into a small glass tube introduce a little of the oxide of tin; let it cover about half an inch of the lower internal surface. Place the tube thus prepared on the table of Henley's discharger, and introduce the pointed wires at each end, that the oxide may form part of the circuit. Pass now several strong charges in succession through the tube, taking care to replace the oxide in its proper situation, should it be dispersed. If the charges are strong, the tube will soon become stained with the tin revived from the oxide.

242. In the same way other metallic oxides may be revived; but if vermilion be employed, which consists of sulphur and mercury, the mercury will be separated with such ease as that the charge of a moderately sized jar will be found quite sufficient.

### Decomposition of Water by Electricity.

243. The decomposition of water by electricity was first effected by Van Troostwyk and Deiman, assisted by Mr. Cuthbertson; this they effected by means of a complicated apparatus, and a very tedious process. Their method of procedure was improved on by Dr. Pearson, and after him by Mr. Cuthbertson: but the most simple form of an apparatus for this purpose is that of Dr. Wollaston. This apparatus is thus constructed:—Two finely pointed wires of gold or platina are inserted into capillary tubes; each wire is thrust into the tube till it nearly reaches the end of it, and the glass is softened by heat until it adheres to the wire and covers its point. The glass is then carefully ground away, till the point of the wire can be seen by the help of a magnifying glass. One of these wires is made to communicate with the ground, or with the negative conductor of the machine, and the other with an insulated ball placed near the positive conductor, the two points are placed near each other in a vessel of water; when a current of sparks is discharged through the wires, a series of minute bubbles of gas will rise from the points of the gold wires, and, when collected in an inverted receiver, will explode on the application of a lighted taper. Dr. Wollaston found by experiment, that a point $\frac{1}{700}$ of an inch in diameter, decomposed the water when the spark which passed from the conductor to the insulated ball was $\frac{1}{8}$ of an inch in length; and that a point $\frac{1}{1500}$ of an inch in diameter, produced the same effect when the sparks were only $\frac{1}{20}$ of an inch in length. Hence the rapidity of the decomposition was in proportion to the limited size o the point of the wire.

244. Of the results obtained in some experiments made with this apparatus, Dr. Wollastoi gives the following account. By transmitting a current of sparks by means of two gold point over the surface of a card a little moistened, and tinged with litmus, and placed between the points, a redness was perceived about the positive wire after a few turns of the machine. When the negative wire was placed upon the red spot i was quickly restored to its former color. Hence he infers that the effect of an acid is produced a the positive wire; and that this effect is counteracted by reversing its electricity.

245. Dr. Wollaston next coated two wire with sealing-wax, so that their ends only were exposed: these he inserted into a solution o copper, and found that, on transmitting a curren of sparks between them, the negative wire wa coated with copper: the electricity of the wire being reversed, the copper quickly disappeared

246. When it is wished to decompose oils alcohol, ether, &c., a much more simple, and les expensive apparatus will be found to answe every purpose. This apparatus, which is repre sented by fig. 8, consists of a glass tube having a platina wire projecting from the top inwards an reaching nearly to the lower end. The lowe

extremity is open, and is placed in a metallic dish nearly filled with the fluid which is to be decomposed. The cylinder must be filled with the fluid as receivers are filled with water in the pneumatic trough. When charges are successively sent through the wire, the fluid will be gradually decomposed, and the gaseous product rising to the upper part of the cylinder will displace the liquid. In all experiments of this kind the glass used ought to be very strong to resist the expansion caused by the explosion.

247. Having spoken of the decomposition of water by means of the electric fluid, it may be proper just to notice the process of forming water from the gases that compose it, by the action of the same agency. For this curious experiment Mr. Singer employed the apparatus represented in fig. 9, which consists of a stout globe of glass, with a stop-cock, having a wire passing through its centre to within a short distance of the cap to which the stop-cock is screwed. The globe must be exhausted by means of an air-pump, and then screwed on a receiver containing a mixture of oxygen and hydrogen gases, furnished with a stop-cock. When the cocks are opened, the globe will be filled with the gases; they must then be shut, and a spark passed from the wire in the inside of the globe to the cap. A bright flash follows, and the inside of the globe becomes covered with moisture; the cocks are then to be opened, and more gas will rush into the globe. The cocks being again closed, a second explosion may be made, which will increase the dew on the inside of the globe; and the experiment may be repeated in this way until drops of water may be observed.

248. Such experiments as the preceding naturally led to numerous others on various liquids and also on different gaseous bodies: to detail these would be foreign to our purpose; yet to pass them over in silence would be to do them injustice. We shall, therefore, merely give the results of some remarkably fine experiments by Cavendish, and others, as drawn up in a tabular form by Mr. Singer. The numbers prefixed to some of the gases indicate the proportionate measures employed of each.

| MIXED GASES. | RESULT. |
|---|---|
| Atmospheric air and hydrogen | Water and nitrogen. |
| Oxygen and hydrogen | Water. |
| Chlorine and hydrogen | Muriatic acid. |
| Muriatic acid and oxygen | Chlorine. |
| Carbonic oxide and oxygen | Carbonic acid. |
| Nitrogen and oxygen | Nitric acid. |
| Sulphurous acid and oxygen | Sulphuric acid. |
| Phosphureted hydrogen and oxygen | Water and phosphoric acid. |
| Sulphureted hydrogen and oxygen | Water and sulphurous acid. |
| Oxygen and ammonia | Water and nitrogen.* |
| 100 olefiant gas and 284 oxygen | Carbonic acid and water. |
| 100 olefiant gas and 100 oxygen | Carbonic oxide and hydrogen. |
| 100 carbureted hydrogen and 100 oxygen | Carbonic oxide and hydrogen. |
| 100 carbureted hydrogen and 200 oxygen | Carbonic acid. |

| COMPOUND GASES. | RESULT. |
|---|---|
| Muriatic acid | Hydrogen.* |
| Fluoric acid | Hydrogen.* |
| Nitrous gas | Nitric acid and nitrogen. |
| Carbonic acid | Carbonic oxide and oxygen. |
| Sulphureted hydrogen | Sulphur and hydrogen. |
| Phosphureted hydrogen | Phosphorus and hydrogen. |
| Ammonia | Hydrogen and nitrogen. |
| Olefiant gas | Charcoal and hydrogen. |
| Carbureted hydrogen | Charcoal and hydrogen. |

The results marked with a star are given on the authority of Dr. Henry and Mr. Dalton. In making the above experiments when the mixture consisted of inflammable gases with oxygen, the change was usually effected by a single spark; but in other cases it was found necessary to continue the current of sparks for many hours.

### Electrical Configurations.

249. This is a most interesting and curious branch of mechanical electricity, and one which certainly challenges a more vigorous enquiry than has hitherto been made respecting it. It is thought by some that the experiments which we shall here briefly notice afford satisfactory proof that electricity is the real cause of crystallisation. The subject seems to have been first noticed by professor Lichtenberg, of Gottingen, and afterwards by Mr. Bennet, Cavallo, and others.

250. Excite a plate of any resinous substance, as gum-lac, by friction, and let any metallic body of any shape whatever, a brass ring for instance, be placed upon the plate. Let the ring be then electrified with an electricity opposite to that of the plate, and afterwards removed from the plate by a stick of sealing-wax, or any other non-conductor. Let some powdered resin be now shaken upon the plate, then if the plate has been excited negatively, and the brass ring positively, the powder will fall only on those points of the plate that were touched by the ring, and will form radiating appearances resembling stars, while almost no powder will be found on any other part of the plate. If, on the other hand, the

plate has been electrified positively, while the ring was electrified negatively, the powdered resin will fall only on the parts of the plate which were formerly uncovered, the figures being now indicated by the absence of the powder.

251. Mr. Bennet who repeated with much care the experiments of Lichtenberg, has given the following account of the method which he adopted for rendering figures produced in this way permanent. When it is wished to make the figures red, 'Take a pound of rasped Brasil wood; put it into a kettle with as much water as will cover it, or rather more: also put in about an ounce of gum arabic, and a piece of alum about the size of a large nut; let it boil about two hours, or till the water be strongly colored; strain off the extract into a broad dish, and set it in an iron oven, where it is to remain till all the water be evaporated, which with me was effected in about twelve hours; but this depends on the heat of the oven, which should not be so hot as to endanger its burning. Sometimes I have boiled the strained extract till it was considerably inspissated before it was placed in the oven, that it might be sooner dry.

252. 'When it is quite dry, but not burnt, scrape it out of the dish, and grind it in a mortar till it be finely pulverised. In doing this, it is proper to cover the mortar with a cloth, having a hole through it for the pestle, to prevent the powder from flying away and offending the nose, and also to do it out of doors if the weather be dry and calm, that the air may carry away the powder necessarily escaping, and which otherwise is very disagreeable. When ground, let it be sifted through a fine hair sieve, returning the coarser part into the mortar to be ground again.

253. 'The plate I have mostly used, was composed of five pounds of resin, half a pound of bees'-wax, and two ounces of lamp-black, melted together, and poured upon a board sixteen inches square, edged round with slips of wood, at least half an inch high, to confine the composition whilst fluid: the plate was thus half an inch thick, which is better than a thinner plate, the figures being more distinct. After the composition is cold, it will be found covered with small blisters, which may be taken out by holding the plate before the fire till the surface be a little melted, then let it cool again; and upon holding it a second time to the fire, more blisters will appear; but by thus repeatedly heating and cooling the surface, it will at last become perfectly smooth. Some plates were made smaller, and the resinous composition confined to the form of an ellipsis, a circle, or escutcheon, by a rim of tin half an inch broad, and fixed upon a board.

254. 'The next thing to be done is to prepare the paper, which is to be softened in water, either by laying the pieces upon each other in a vessel of cold water, or first pouring a little hot water upon the bottom of a large dish; then laying upon it a piece of paper, so that one edge of the paper may lie over the edge of the dish, to remain dry, that it may afterwards be more conveniently taken up. Then pour more hot water upon its upper surface. Upon this place another piece in the same manner, again pouring on more water, and thus proceed till all the pieces are laid in. By using hot water, the paper will be softened in a few minutes.

255. 'When the figures are to be made, the resinous plate must lie horizontally, whilst the electricity is communicated, if the experiment requires any thing to be placed upon the plate: but it is convenient afterwards to place it in a vertical position whilst the powder is projected, lest too much powder should fall where it is not required.

256. 'A little of the powder may be taken between a finger and thumb, and projected by drawing it over a brush; or, what is better, a quantity of it may be put into the bellows and blown towards the plate. When the figure is sufficiently covered with powder, let the plate be again laid horizontally upon a table; then take one of the softened papers out of the water by its dry edge, and lay it carefully between the leaves of a book, pressing the book together, and permitting it to lie in this situation about half a minute. Then remove the paper to a dry place in the book, and press it again about the same time, which will generally be sufficient to take off the superfluous moisture. Then take up the paper by the two corners of its dry edge, and place the wet edge a little beyond the figure on the resinous plate, lowering the rest of the piece gradually till it covers the figure without sliding; then lay over it a piece of clean dry paper, and press it gently; let it remain a short time, and then rub it closer to the plate with a cloth; or, which is better, press it down by means of a wooden roller covered with cloth, taking care that the paper be not moved from its first position.

257. 'When the paper is sufficiently pressed, let it be taken up by its dry edge, and laid upon the surface of a vessel of water, with the printed side downwards; by this means the superfluous powder will sink in the water, and the figure will not be so liable afterwards to spread on the paper. After the paper has remained on the water a few minutes, take it up and place it between the leaves of a book, removing it frequently to a dry place. If it be desired that the paper should be speedily dry, let the book-leaves in which it is to be placed be previously warmed, and by removing it to several places it will be dry much sooner than by holding it near a fire. By the above process, it is obvious that leather, calico, or linen, as well as paper, may be printed with these figures, and the effects of the diffusion of electricity upon a resinous plate be exhibited to those who have not leisure or inclination to perform the experiments.'

258. To the above it may be proper to add, that with a resinous plate of the kind now described, a very beautiful exhibition may be made of the different powers of positive and negative electricity. For this purpose prepare equal quantities of red lead and resin, by weight, finely powdered and intimately mixed, by being sifted together through a fine hair sieve. Put this powder into a bottle of India rubber for use. Let now a small jar be charged at the positive conductor of the machine, and, with its knob,

quickly write the letter P on the resinous plate: take the bottle containing the mixed powders, and by gently striking the sides of it between the palms of the hands, the mouth of it being directed towards the plate, which must be placed in a vertical position, project on the electrified part a little of the powder, and the letter will instantly appear, well defined, and covered with the red lead, while the resin will be dispersed. If now the whole be wiped clean off, and, with a jar charged at the negative conductor, the letter N be written on the plate, and the powder projected as before, it will be found that the negative electricity has selected the resinous particles for the formation of the letter, while those of the red lead have been rejected.

### Magnetic Effects of Electricity.

259. The connexion between magnetism and electricity will be fully treated of in a subsequent part of this article; at present we shall merely offer the following general remarks in the way of showing the amount of what was known on the subject previously to the interesting discoveries recently made.

260. Dr. Franklin appears to have been the first who paid any serious attention to this subject. He sent the charge of some large electrical jars through fine sewing-needles; the ends of the needles were rendered blue, and on being carefully laid on water they traversed, evincing evident proofs of polarity. The most remarkable circumstance attending these experiments was, that if the needle lay east and west when the charge was passed through it, the end which was entered by the fluid pointed to the north: but if it lay south and north, the end which lay pointing to the north would continue to do so, whether the charge entered by that end or the other; although the Dr. imagined that a still stronger charge would have reversed the poles, even in that situation, since this effect had been actually produced by lightning. The polarity he also found to be strongest when the needle received the charge while lying north and south, and weakest when it lay so as to point east and west.

261. But the experiments most to be relied on were made by Van Marum with the large machine and battery in the Tylerian museum at Haarlem. He and his assistants tried to give polarity to needles made of watch-springs, of from three to six inches in length; and also to steel bars nine inches long, from a quarter of an inch to half an inch broad, and about a line in thickness. The result was, that when the bar was placed horizontally in the magnetic meridian, whichever way the shock entered, the end of it that stood toward the north acquired the north polarity, and the opposite end acquired the south. If the bar, before it received the shock, had some polarity, and was placed with its poles contrary to the usual direction, its natural polarity was uniformly diminished, and often reversed; so that the extremity of it, which in receiving the shock pointed to the north, became the north pole, &c.

262. When the bar was struck standing perpendicularly, its lowest end became the north pole in any case, even when the bar had previously some magnetism, and was placed with the south pole downwards. Things remaining the same, the bars seemed to acquire an equal degree of magnetic power, whether they were struck whilst standing horizontally in the magnetic meridian, or perpendicular to the horizon. When the needle was placed in the magnetic equator, whichever way the charge entered, it never produced any magnetism; but if it was passed through its width, then the needle acquired a considerable degree of magnetism, and the end which lay towards the west became the north pole, and the other end the south pole. If a needle or bar, already magnetic, or a real magnet, was struck in any direction, its power was always diminished. For this experiment they used considerably large bars, one of which was 7·08 inches long, 0·26 broad, and 0·05 thick. When the shock was so strong in proportion to the size of the needle, as to render it hot, then the needle generally acquired no magnetism at all, or very little. These experiments were made with the power of a battery composed of 135 phials, containing among them about 130 square feet of coated surface.

### Medical Electricity.

263. The very remarkable properties of the electric fluid seem to have occasioned the application of its powers to organised bodies at an early period of its history; and the results, whether real or imaginary, gave rise to various opinions, which are now only viewed as monuments of credulity and imposture. It is not our intention to enter here minutely into an investigation of this department of the science of electricity; yet, although this would be improper on several grounds, we must not pass it over in silence. The application of electricity as a medical agent has recently been much revived; but that application is, we believe, most successfully made in the form of Voltaic electricity; and will therefore fall, with more propriety, under consideration in another place. From the numerous respectable testimonies extant, as to the real utility of electricity in the healing art, we shall make a choice selection, which it is hoped will satisfy the reader, that in the hands of a skilful operator, it may be applied in numerous instances with certainty of success. Let it however be observed that no one ought to attempt its application who is not thoroughly conversant with the use of the apparatus, and capable of forming a correct judgment, as to the strength and duration of the application.

264. Speaking of the power of the apparatus which ought to be used in the application of electricity for medical purposes, Mr. Singer justly remarks, that the machine employed ought to be such as will furnish a constant stream of sparks; if a plate machine, it ought to be two feet in diameter; if a cylinder machine, not less than ten inches, and fourteen if possible. Machines called medical electrical machines, are sometimes made on a very small scale, and hence the application of them only produces trouble, waste of time, and final disappointment.

265. In connexion with a *powerful* electrical

machine, the auxiliary apparatus requisite for medical purposes are the following:—A jar fitted up with Lane's electrometer, by which shocks may be given of any required force. A pair of directors, each consisting of a glass handle, surmounted by a brass cap with a wire of a few inches in length, having a ball screwed on its extremity, which may be occasionally unscrewed and a wooden point substituted for it. When shocks are given by means of these directors, they must be applied at the opposite extremities of the part through which the charge is required to pass; and being respectively connected by conducting wires, the one with the outside of the jar and the other with the receiving ball of the electrometer previously placed at the requisite distance, the jar may be set to the machine, which is then put in motion until any required number of shocks has been given.

266. The insulated director is also employed to give sparks, being held by its glass handle, and its ball previously connected with the conductor by a fine chain being brought near the patient, or rubbed lightly over a piece of flannel or woollen cloth laid on the affected part. When the eye or any delicate organ is electrified, the ball of the insulated director is unscrewed and the wooden point applied, at the distance of about half an inch from the part. The stream of electricity which passes from the point, in such cases, produces rather a pleasant sensation than otherwise.

267. An insulated stool is sometimes employed; it should be of sufficient size to receive a chair upon it, with a resting place in front of the chair for the feet. The patient being placed on the insulated chair, and connected with the conductor of the machine by means of a chain, sparks may be drawn from any part of the body by a person who stands on the ground and presents a brass ball to it.

268. The following enumeration of instances of disease in which electricity has been successfully applied, is given by Mr. Singer as established on good authority:—1. Contractions. Those only that depend on the affection of a nerve; and in many of these it has been employed without effect, whilst in others of long duration immediate relief has been obtained. 2. Rigidity. Very frequently relieved, but usually requiring some perseverance in the application, to complete the cure. 3. Sprains, relaxation, &c. Electricity may be applied in all these cases with good effect, but its application should be deferred until the inflammation has subsided. 4. Indolent tumors. Strong sparks, and slight shocks, are often effectual. The most numerous cases are those of scirrhous testicle; and there are some instances of the successful dispersion of scirrhous induration of the breast. 5. Mr. Carpue states, that electricity is a good preventive against chilblains; and mentions two instances in which they were removed by the action of electrical sparks. 6. Epilepsy. In several instances of persevering application, not one successful case occurred. 7. Deafness. Sparks thrown on the mastoid process, and round the meatus auditorius externus, and drawn from the same parts on the opposite side, usually afford relief; and about one in five are permanently cured. 8. Opacity of the cornea. This is sometimes cured by the long continued action of electricity thrown for ten minutes a day on the eye by a wooden point. When caused by the small-pox, it is said to yield most readily. 9 Gutta serena. The method of electrifying for opacity of the cornea has been successful in some instances of gutta serena; but there are numerous unsuccessful cases. 10. Amenorrhæa. Cases of suppressed menstruation are generally relieved by sparks and slight shocks; but in retention of the menses electricity has been tried without success. 11. Knee cases. In instances of pain and swelling of the knee, the application of sparks has been effectual in about one case in ten. 12. Chronic rheumatism. Very numerous are the instances of success; the usual application is by sparks, for ten or fifteen minutes every day. In recent cases, a few days is sometimes sufficient; but in those of long standing, very considerable perseverance is often required. 13. Acute rheumatism. In one case out of six a cure was effected in about a month by the application of electricity. 14. Palsy. Moderate shocks, with sparks, have been occasionally successful in about one case of paralysis in every fourteen that have been tried. 15. St. Vitus's dance has been frequently relieved by electricity. There are indeed scarcely but few diseases in which some successful instances of its application are not recorded; but we are still in want of a scientific examination of the statements that have been made on this subject.

269. It appears that the nerves are most powerfully affected by electricity, since the effect of a discharge sent through the body is always most conspicuous in their direction. When the charge of a battery is sent through the head of a bird, the optic nerve is generally found to be injured, and often completely destroyed; a like discharge sent through a larger animal is found to produce a universal protraction of strength, with trembling and depression. Mr. Singer says he once accidentally received a considerable charge from a battery, through the head, which produced the sensation of a violent but universal blow, followed by a transient loss of memory and indistinctness of vision, but was unattended by any permanent injury.

270. Mr. Morgan, who paid considerable attention to medical electricity, has remarked, that if the diaphragm be made to form part of the circuit of a coated surface equal to two feet, fully charged, the lungs make a sudden effort, which is followed by a loud shout; but that if the charge be small, it never fails to produce a violent fit of laughter; and that even those whose calmness and solemnity are not easily disturbed by ludicrous occurrences, are seldom able to withstand the powers of electricity. The first effect of a strong charge on the diaphragm is frequently followed by involuntary sighs and tears, and sometimes by a fainting fit If the charge be passed through the spine, it produces a degree of weakness in the lower extremities; so that if a person be standing at the time, he sometimes drops on his knees, or falls prostrate on the floor.

271. Numerous cases of the successful application of electricity as a medical agent have been published by different authors; Mr. Cavallo has related some of a very striking nature, as have also Mr. Carpue, and Mr. Ferguson, whose testimony stands high in consequence of the candor and unaffected simplicity of their narrations. To the above-mentioned names we must add the name of Mr. La Beaume, who has recently published an excellent little work on the Application of Galvanic Electricity in the cure of chronic diseases; to these works the reader is referred for more ample information on the subject than our limits will allow us to give.

## PART IV.

### ATMOSPHERICAL ELECTRICITY.

272. In the preceding parts of this article we have had occasion to make several references to the identity of lightning and the electricity excited by artificial means; we now proceed to show, by a selection of strictly appropriate experiments, that that agent which is ever active in the atmosphere which surrounds our earth, and is occasionally producing some of the most astonishing, and awfully grand phenomena of nature, is nothing more than a vast explosion of accumulated electricity.

273. The discovery of this important fact was by no means an instantaneous thing; even some modern writers on philosophy appear to have formed opinions on the nature of lightning essentially incorrect; and this is the more remarkable when it is considered that, so long ago as the days of the abbé Nollet, such remarks as the following should have been published, and read, and verified by actual experiment soon after. 'If,' said the abbé, 'any should take upon him to prove, from a well-connected comparison of phenomena, that thunder is in the hands of nature what electricity is in ours; that the wonders we now exhibit at pleasure are little imitations of those great effects which frighten us; and that the whole depends on the same mechanism:—if it could be shown, that a cloud prepared by the action of the winds, by heat, by a mixture of exhalations, &c. is, when opposite to a terrestrial object, that which an electrified body is, when at a certain distance from one that is not electrified; I confess this idea, if it were well supported, would afford me much pleasure; and to support it, how many specious reasons present themselves to a man well versed in electricity. The universality of the electric matter, the rapidity of its action, its inflammability, and its activity in inflaming other bodies; its property of striking bodies externally and internally, even to their smallest parts, the remarkable example we have of this effect in the Leyden experiment, the idea we may legitimately form in supposing a greater degree of electric power, &c. All these points of analogy, which I have for some time meditated, begin to make me believe that one might, by taking electricity for a model, form to one's-self, in relation to thunder and lightning, more perfect and probable ideas than any that have been hitherto offered.'

274. This was certainly a bold hypothesis; highly creditable to the judgment of the author, and affording no obscure intimation that electricity was about to make some unprecedented degree of progress; but to Dr. Franklin undoubtedly belongs the honor of accomplishing, by actual experiment, all that the abbé Nollet's penetrating sagacity led him to speak of in the words just quoted. In a series of letters to one of the members of the Royal Society, the Dr. first gave in detail an hypothesis to explain the phenomena of thunder and lightning by the known properties of electricity, which was soon followed by a demonstration of its truth in the most remarkable experiment ever made.

275. The following are the leading points of resemblance which Dr. Franklin observed to obtain between the electricity of the atmosphere and that which is produced by artificial means. (1.) The zig-zag appearance of the lightning is exactly the same as that of a strong electric spark when it passes through a considerable interval of air. (2.) Lightning generally strikes such bodies as are high and prominent, as the summits of high hills, the tops of lofty trees, high towers, spires, masts of ships, points of spears, &c. and the electric fluid always passes through the most prominent parts, when striking from one body to another. (3.) Lightning is observed to strike most frequently into those substances that are good conductors of electricity, such as metals, water, and moist substances; and to avoid those that are non-conductors. (4.) Lightning inflames combustible bodies. The same is effected by electricity. (5.) Metals are melted by a powerful charge of electricity. This phenomenon is one of the most common effects of a stroke of lightning. (6.) The same may be observed of the fracture of brittle bodies, and of other expansive effects common to both causes. (7.) Lightning has been known to strike people blind. Dr. Franklin found, that the same effect is produced on animals when they are subjected to a strong electric charge. (8.) Lightning destroys animal life. Dr. Franklin killed turkeys of about ten pounds weight, by a powerful electric charge. (9.) The magnetic needle is affected in the same manner by lightning and by electricity, and iron may be rendered magnetic by both causes. The phenomena are, therefore, strictly analogous, and differ only in degree; and, if an electrified gun-barrel will give a spark, and produce a loud report at two inches distance, what effect may not be expected from perhaps 10,000 acres of electrified cloud? And is not the different extent of these conductors, equal to the different limit of their effects?

276. Reasoning on these strong resemblances, Franklin formed the design of erecting a conducting rod by which the lightning might be drawn from the clouds, and thus afford an opportunity of ascertaining its identity with the electric fluid. 'The electric fluid,' said he, 'is attracted by points; we do not know whether this property be in lightning; but since they agree in all the particulars in which we can already compare them, it is not improbable that in this they likewise agree. Let the experiment be made.' And doubtless he would himself have made it before

any other person could have anticipated him in it, but waiting for the erection of a spire in Philadelphia, and his opinions becoming known, he was anticipated by the French philosophers D'Alibard and De Loe, who erected a rod such as Franklin had suggested, and succeeded in the experiment. But the honor and merit of the idea were not to be thus rent from Franklin; for in the mean time, and without any knowledge of the attempts of the French electricians, it occurred to him that, by sending up a kite, he could obtain a readier access to the clouds than by the longest rod which he could raise on the highest spire. He made the attempt, and, as we have before shown, was successful; and thus was the identity of lightning with electricity satisfactorily established.

277. In treating of the electricity of the atmosphere it may be proper to begin with the more gentle and silent manifestations of it: thence to proceed to the consideration of its accumulated discharges in meteors and thunder-storms; and then make some remarks on its general influence on the surface of our earth.

278. From long, correct, and patient investigation, it has been proved that the various luminous phenomena that appear in our atmosphere, are to be resolved into the agency of electricity, although it must be allowed that, with all our knowledge of those effects, they are still surrounded with such difficulties, that scientific men are not quite of one mind respecting them. Of this description the aurora borealis, or northern light, must be allowed to be an instance.

279. The aurora borealis, or, as the same appearance is commonly termed, streamers, and in the Shetland Isles, the merry dancers, can seldom be seen in the southern parts of the kingdom; and, even when seen there, the appearance is far less brilliant than in northern latitudes, where this wonderful phenomenon is the constant attendant of clear evenings, affording a great relief to the inhabitants, amid the gloom that would otherwise attend their dreary winter nights.

280. Of this kind of meteor, the late Mr. George Adams has given the following concise account in his valuable lectures:—The appearances of the aurora come under four different scriptions. (1.) A horizontal light, like the aurora, or break of day. (2.) Fine, slender, luminous beams, well defined, and of dense light. These often continue a quarter, a half, or a whole minute, apparently at rest, but oftener with a quick lateral motion. (3.) Flashes pointing upward, or in the same direction with the beams, which they always succeed. These are only momentary, and have no lateral motion; but they are generally repeated many times in a minute. They appear much broader, more diffuse, and of a weaker light than the beams: they grow gradually fainter till they disappear; and sometimes continue for hours, flashing at intervals. (4.) Arches, nearly in the form of a rainbow: these, when complete, go quite across the heavens, from one point of the horizon to the opposite point.

281*. When an aurora happens, these appearances seem to succeed each other in the following order:—(1.) The faint rainbow-like arches; (2.) The beams; and (3.) The flashes. As for the northern horizontal light, it appears to consist of an abundance of flashes of beams, blended together by the situation of the observer.

The beams of the aurora borealis appear at all places to be arches of great circles of the sphere, with the eye in the centre; and these arches, if prolonged upwards, would all meet at one point.

The rainbow-like arches all cross the magnetic meridian at right angles. When two or more appear at once they are concentric, and tend to the east and west; also the broad arch of the horizontal light tends to the magnetic east and west, and is bisected by the magnetic meridian; and when the aurora extends over any part of the hemisphere, whether great or small, the line separating the illuminated part of the hemisphere from the clear part is half the circumference of a great circle crossing the magnetic meridian at right angles, and terminating in the east and west: moreover, the beams perpendicular to the horizon are only those on the magnetic meridian.

That point in the heavens to which the beams of the aurora appear to converge, at any place, is the same as that to which the south pole of the dipping-needle points at that place.

The beams appear to rise above each other in succession; so that, of any two beams, that which has the higher base has also the higher summit.

Every beam appears broadest at or near the base, and to grow narrower as it ascends; so that the continuation of the bounding lines would meet in the common centre to which the beam tends.

281*. Now between these appearances and those of electricity, under certain circumstances, there are several points of close resemblance. For it is found by a simple experiment that, when the electric fluid is made to pass through rarefied air, it exhibits a diffused luminous stream, which has all the characteristic appearances of the northern lights. There are to be seen the same varieties of color and intensity, the same undulating motion and occasional corruscations; the streams exhibit the same diversity of character, at one moment minutely divided into ramifications, and at another beaming forth in one body of light, or passing in well defined flashes; and, when the rarefaction is high, various parts of the stream assume that peculiar glowing color which occasionally appears, and which, on the whole, leaves but little room to doubt that the phenomena are produced by the passage of electricity through the upper regions of the atmosphere, although at the same time it ought to be mentioned that this opinion has been doubted by some since the accomplishment of the recent voyages of discovery to the polar regions.

282. It has been stated above, that this most beautiful phenomenon is seldom witnessed by the inhabitants of the southern parts of the kingdom; to them, therefore, at all events, as well as to those who have witnessed the aurora borealis in a fainter degree, the following extract from

Mr. Dalton's description of one which he witnessed must be acceptable. It is taken from his Meteorological Essays.

283. 'Attention,' says Mr. Dalton, 'was first excited by a remarkably red appearance of the clouds to the south, which afforded sufficient light to read by, at eight o'clock in the evening, though there was no moon, nor light in the north. Some remarkable appearance being expected, a theodolite was placed to observe its altitude, bearing, &c.

'From half past nine to ten o'clock, P. M., there was a large, luminous, horizontal arch to the southward, almost exactly like those which we see in the north; and there were some faint concentric arches northward. It was particularly noticed that all the arches seemed exactly bisected by the plane of the magnetic meridian. At half past ten o'clock streamers appeared very low in the south-east, running to and fro from west to east; they increased in number, and began to approach the zenith apparently with an accelerated velocity; when all on a sudden the whole hemisphere was covered with them, and exhibited such an appearance as surpasses all description. The intensity of the light, the prodigious number and volatility of the beams, the grand intermixture of all the prismatic colors in their utmost splendor, variegating the glowing canopy with the most luxuriant and enchanting scenery, afforded an awful, but at the same time the most pleasing and sublime spectacle. Every one gazed with astonishment; but the uncommon grandeur of the scene only lasted about one minute; the variety of colors disappeared, and the beams lost their lateral motion, and were converted into the usual flashing radiations; but even then it surpassed all other appearances of the aurora, in that the whole hemisphere was covered with it.

284. 'Notwithstanding the suddenness of the effulgence at the breaking out of the aurora, there was a remarkable regularity in the manner. Apparently a ball of fire ran along from east to west, and the contrary, with a velocity so great as to be barely distinguishable from one continued train, which kindled up the several rows of beams one after another: these rows were situated before each other with the most exact order, so that the bases of each row formed a circle crossing the magnetic meridian at right angles; and the several circles rose one above another in such sort, that those near the zenith appeared more distant from each other than those near the horizon, a certain indication that the real distances of the rows were either nearly or exactly the same. And it was further observable that, during the rapid lateral motion of the beams, their direction in every two nearest rows was alternate; so that whilst the motion in one row was from east to west, that in the next was from west to east.

285. 'The point to which all the beams and flashes of light uniformly tended was, in the magnetic meridian, and, as near as could be determined, between 15° and 20° south of the zenith. The aurora continued, though diminishing in splendor, for several hours. There were several meteors seen at the same time; they appeared below the aurora, and unconnected with it.' This brilliant display of the aurora borealis Mr. Dalton witnessed on the 13th of October, 1792.

286. Similar appearances are often seen towards the south pole, but they are said to be unattended with the same variety of color; they are called aurora australis. A very feeble, though certainly a pleasing imitation of this remarkable phenomenon may be thus exhibited:—Take the glass vessel represented in fig. 9, resembling a Florence flask, and fitted with a valve at top by which it may be exhausted of its air: when exhausted, and rubbed in the common manner used to excite electrics, it will appear luminous within, being full of a flashing light which plainly resembles the aurora borealis, or northern light. This phial may also be made luminous, by holding it by either end, and bringing the other end to the prime conductor; in this case all the cavity of the glass will instantly appear full of flashing light, which remains in it for a considerable time after it has been removed from the conductor: instead of the glass phial a glass tube exhausted of air and hermetically sealed may be used, and perhaps with more advantage. The most remarkable circumstance of this experiment is, that if the phial or tube, after it has been removed from the conductor (and even several hours after its flashing light has ceased to appear), be grasped with the hand, strong flashes of light will immediately appear within the glass, which often reach from one end to the other.

287. The next form of atmospherical electricity that claims our attention is that which it assumes in those meteors, to which the vulgar name of falling, or shooting stars, has been given. The aurora borealis, we have said, is caused by streams of the electric fluid passing rapidly through the higher regions of the air; and these phenomena of which we are now speaking, are, in all probability, portions of the same matter moving through a more resisting medium, since they are always observed to be in comparatively small altitudes.

288. These meteors vary considerably in their size and color, and also in the rapidity of their motion; they move in various directions, but chiefly incline towards the earth. They occur in different states of the atmosphere, but prevail most in clear frosty nights, and at other times when the winds are easterly, and the sky clear; in the intervals also of showery weather they are frequent, and on summer evenings, when well defined clouds are seen floating in a clear atmosphere.

289. In favorable states of the atmosphere, Mr. Singer remarks, these appearances are seen to succeed each other so rapidly, that he has often counted thirty of them in the space of an hour, and, on some occasions, twice that number. The frequency of their occurrence, he thinks, indicates that they are produced by some of the usual atmospherical changes, and that the circumstance of their explosion being unattended by the fall of stones, renders it almost certain that their nature is essentially different from that of the large meteors.

290. The same gentleman offers the following as arguments in favor of the electrical origin of

these meteors:—(1.) The light of falling stars is similar to the light of the electric spark. (2.) They occur as frequently and as irregularly as other electrical changes in the atmosphere. (3.) Their motion, like that of electricity, is exceedingly rapid; and the longest interval through which they strike, is traversed in an interval of time too minute to admit of measurement. (4.) They occur most frequently during, or near to those changes of weather, that are known to influence the electrical state of the atmosphere. (5.) Their direction is never constant; they occur in every part of the atmosphere, and move in almost every direction; such is also the case with lightning. (6.) The appearance of falling stars may be accurately imitated by electricity; and the circumstances on which the success of such experiments depend, are such as are likely to occur in the production of the natural phenomena.

291. Hence if electricity be passed gradually through an exhausted receiver, it assumes, as we have already seen, the appearance of the aurora borealis; but if an accumulation of it be suddenly transmitted, it will pass through the receiver with the straightness and brilliance of a shooting star. This appearance also occurs most readily when the receiver is but partially exhausted. The imitation therefore of these two phenomena seems evidently to require the same conditions for its production, as those which obtain in nature; that is to say, the aurora occurs in those regions where the air is highly rarefied; and the most complete imitation of it is effected in a thoroughly exhausted receiver; falling stars take place where the air is much more dense, and the imitation of them requires a medium which offers from its density considerable resistance.

292. Different writers on electricity have proposed different methods of producing an imitation of these meteors, but that of Mr. Singer is undoubtedly the most effectual as well as the most elegant. He used for this purpose a glass tube, five feet in length, and about five-eighths of an inch in diameter, mounted with a brass cap at each end, and fitted at one extremity with a valve to allow of its being exhausted. When this tube was exhausted, no spark would pass through it except in a very diffused state; but when the charge of a very large jar was employed, a brilliant spark was obtained through the whole length of the tube, resembling in appearance a shooting star.

293. There are various other luminous appearances of the electricity of the atmosphere, which might with propriety be described here, such as those frequently observed on the tops of spires, and the masts of ships, and occasionally on the points of spears, &c.; but we must not enlarge, and shall only observe respecting them, that they seem analogous to the light that is observed on the point of any slender and prominent conductor, when placed within an electrical atmosphere, or brought near to an excited electric. These, and similar phenomena observable in the atmosphere, have now been sufficiently treated for this department of our work. 58

294. But the most magnificent display of atmospherical electricity is to be seen during a thunder-storm, the particular phenomena of which we must now proceed to notice. We have already seen the most satisfactory ground for the conclusion that lightning and electricity are identical, and have adverted to most of the known means by which the latter are produced: and if the analogy be correct in the one case we may conclude it to be so in the other, although with some differences perhaps, which have hitherto been, and which may for ever remain inaccessible to human observation.

295. If then, it be asked, whence comes the electricity of the atmosphere? it may in reply be said, that from the sum of our knowledge respecting meteorological phenomena, there appears good reason to conclude that the causes which produce artificial electricity, are all in full operation in the masses of vapor, among which natural electricity appears active.

296. This opinion is maintained by several eminent practical electricians of the present day; it was warmly espoused by the late Mr. Singer, who advanced in support of it the following positions:—(1.) That the electrical phenomena of the atmosphere take place, in all climates, to the greatest extent, about the period of the greatest degree of heat, when the rays of the sun have caused a considerable accumulation of vapor. (2.) Where this cause operates to the greatest extent, as, for instance, within the tropics, natural electricity is produced on the largest scale. (3.) When the natural source of evaporation is assisted by collateral causes, electrical changes occur with astonishing activity, as in the eruption of a volcano, or the heat imparted to the air in its passage over large extents of hot sands, as those of Africa. (4.) By the action of winds, currents of air of different temperatures are often mixed,—so that such as have been heated and charged with moisture, become suddenly cooled, thus occasioning a precipitation of water, and the occurrence of electrical changes. This is often witnessed on the coast of Guinea during the existence of the harmattan. (5.) These electrical changes are every where most frequent when the causes of evaporation and condensation suddenly succeed each other.

297. After advancing several cogent arguments in favor of the above facts, and noticing in a very candid manner some objections urged against the theory they are intended to support, Mr. Singer concludes with the following truly appropriate and judicious observations:—'Although the immediate causes by which the various phenomena of the atmosphere are produced, be still far beyond our comprehension; yet the connexion of their several effects is a sufficient demonstration that they are not purely mechanical, but subservient to the direction of supreme power and intelligence. By this means the most simple arrangement becomes the source of sublime effects. The process of evaporation which modifies the action of the sun's rays, and conveys to every part of the earth's surface a source of fertility, does at the same time diversify the appearance of the atmosphere by an endless variety of imagery, enlivening the horizon with the most brilliant and glowing tints

and in all probability effecting those electrical changes, which are the precursors of the most magnificent phenomena in nature.'

298. The phenomenon of the thunder-storm itself is always one of intense interest to the electrician. Some writers on the subject of electricity have furnished us with very beautiful descriptions of a thunder-storm, but of all these we feel disposed to give the preference to that of Sig. Beccaria, as containing a neat and unvarnished statement of facts, instead of being decorated with the effusions of a poetical imagination.

299. 'Thunder-storms,' says Beccaria, 'generally happen when there is little or no wind; and their first appearance is marked by one dense cloud, or more, increasing very fast in size, and rising into the higher regions of the air; the lower surface black, and nearly level, but the upper finely arched, and well defined. Many of these clouds seem frequently piled one upon another, all arched in the same manner; but they keep continually uniting, swelling, and extending their arches.

300. 'At the time of the rising of this cloud, the atmosphere is generally full of a great number of separate clouds, motionless, and of odd and whimsical shapes. All these, upon the appearance of the thunder-cloud, begin to move towards it, and become more uniform in their shapes as they approach, till, coming very near the thunder cloud, they mutually stretch towards one another, immediately coalesce, and together make one uniform mass. But sometimes the thunder-cloud will swell, and increase very fast, without the conjunction of these adscititious clouds, the vapors of the atmosphere forming themselves into clouds wherever it passes. Some of the adscititious clouds appear like white fringes at the skirts of the thunder-cloud, but these are continually growing darker and darker as they approach or unite with it.

301. 'When the thunder-cloud is grown to a great size, its lower surface is often ragged, particular parts being detached towards the earth, but still connected with the rest. Sometimes the lower surface swells into various large protuberances, bending uniformly towards the earth. When the eye is under the thunder-cloud, after it is grown larger, and well formed, it is seen to sink lower, and to darken prodigiously; at the same time that a number of adscititious clouds (the origin of which can never be perceived) are seen in a rapid motion, driving about in every direction under it. While these clouds are agitated with the most rapid motions, the rain generally falls in the greatest plenty; and, if the agitation is exceedingly great, it commonly hails.

302. 'While the thunder-cloud is swelling, and extending its branches over a large tract of country, the lightning is seen to dart from one part of it to another, and often to illuminate its whole mass. When the cloud has acquired a sufficient extent, the lightning strikes, between the cloud and the earth, in two opposite places, the path of the lightning lying through the whole body of the cloud and its branches. The longer this lightning continues the rarer the cloud grows, and the less dark is its appearance, till at length it breaks in different places, and displays a clear sky.'

303. From the circumstance of almost constant injury attending thunder-storms it is impossible to witness one without some feelings of personal danger; in this case attention to the following observations may often be of service in relieving the mind from unnecessary fear, or in suggesting the necessary steps to be taken for the prevention of accident.

304. *The Place of the Explosion.*—The electrical explosion generally takes place in the air, and at a considerable height; but in many instances it happens between the clouds and the earth. In most instances, perhaps, the lightning descends from the clouds to the earth, and the explosion is then called the descending stroke: but in some cases it is known to pass from the earth to the clouds, and is then termed the ascending stroke: of the latter kind appears to have been the explosion which took place on the Malvern hills, in the summer of 1826, and which was attended with such melancholy consequences. A very curious instance of the ascending stroke is related by G. F. Richter, in his work on thunder. He informs us that in the cellar belonging to the Benedictine monks of Fontigno, while the servants were employed in pouring into a cask some wine which had been just boiled: a fine light flame appeared round the funnel, and they had scarcely finished their operation when a noise like thunder was heard; the cellar was instantly filled with fire; the cask was burst open, although hooped with iron, the staves were thrown with prodigious violence against the wall; and, on examination, a hole of three inches diameter was found in the bottom of the cask.

305. *The Distance of the Thunder Cloud.*—This is a point of some importance to be determined; and the interval between the flash and the commencement of the report furnishes the data necessary for the calculation. Sound travels at the rate of 1142 feet in a second: consequently, by a watch which beats and points the seconds, the distance of the cloud is easily ascertained, for the flash and the sound are really contemporaneous; and the former requires hardly any perceptible lapse of time to travel through any ordinary distance. Thus, for example, suppose the flash to occur five seconds before the sound is heard, then $1142 \times 5 = 5710 = 1$ mile 430 feet, the distance of the explosion from the place of the observer. So far this calculation is very gratifying, but it is no criterion of safety, for it only indicates the distance of a discharge that has taken place: the next may render the observer incapable of observation.

306. *Indications of real danger.*—During a thunder-storm there are certain circumstances which afford strong indications of actual danger. Such, for instance, are a rapid approach of the charged cloud, and the almost perpendicular direction of the lightning. When the cloud seems to be vertical as soon as it is formed, we are exposed to its utmost fury; and, when it increases in darkness as it approaches, it also indicates great danger. When the flashes strike perpen-

dicularly, it is a certain indication that the clouds are at that height from which they may readily strike into the ground. It is also supposed that the appearance of two flashes at once indicates danger; but this is uncertain, as it may arise from an optical illusion, or the interposition of a cloud.

307. The precautions generally offered by writers on electricity, as necessary for the safety of those who are exposed to the action of a thunder-storm, may be thus enumerated. Shelter should not be taken under trees, hedges, &c.; for, should they be struck, such situations are particularly dangerous; at the same time a person is much safer at about thirty or forty feet from such objects than at a greater distance, as they are likely to operate as conductors. Large portions of water also ought to be carefully avoided if possible, and even streamlets that may have resulted from recent rain; these are good conductors, and the height of a human being connected with them, may sometimes determine the course of the lightning. In a house the safest situation is considered to be the middle of the room; and this situation may be rendered still more secure bystanding on a glass-legged stool: but, as such an article is not in the possession of many people, a hair mattress, or a thick woollen hearth rug makes a very good substitute. It is very injudicious to take refuge, as some persons do, in the cellar during a thunder storm, since the discharge is often found to be from the earth to the clouds, and many instances are recorded of buildings that were struck having sustained the greatest injury about the basement story. But, whatever situation is chosen, the greatest care should be taken to avoid going near the fire-place, since the chimneys are most likely to attract the fluid, and even if there be no fire in the grate, at the time, it should be remembered that soot is a powerful conductor. The same caution is necessary with respect to all large metallic surfaces; gilt furniture, bell wires, &c.

308. But the most important and useful application that has ever yet been made of the discoveries of the electrician is in the method of securing buildings, ships, &c., from the effects of lightning. To the ingenuity of Dr. Franklin the world is indebted for this invention, as well as for his discovery of the identity of lightning and common electricity. He first proposed to erect a perfectly continuous metallic rod by the side of any building intended to be secured from injury by lightning: this rod was to be pointed at each extremity; to rise some feet above the highest part of the building, and to extend some feet below the foundation, in moist ground, or water if practicable. By such a precaution, he conceived that the house could never receive any damage; for, whenever the lightning should happen to fall upon it, it is evident that the conductor, being of metal, and higher than any part of the building, would naturally attract it, and, by conducting it to the ground, prevent that building from receiving any damage; it being well known that electricity always strikes the nearest and best conductors.

309. As this subject is of the utmost importance, we shall here quote the very concise and judicious observations of Mr. Cava o respecting it. Speaking of the proposal of Dr. Franklin, which we have just noticed, he proceeds to remark, that the reasonableness and truth of such an assertion has been confirmed by numberless facts, and the practice of raising such conductors has been found exceedingly useful, particularly in hot climates, where thunder storms are very frequent, and the damage occasioned by the same too often experienced.

310. In regard to the construction of such conductors, there have been some controversies among electricians; and the most advantageous manner of using them has not, without a great many experiments, and but very lately, been ascertained. Some philosophers have asserted, that such conductors should terminate in an obtuse end, that they might the less invite the lightning from the clouds; for such an end will not attract electricity from so great a distance as a sharp point. But other philosophers have thought a pointed termination to be much preferable to an obtuse one; and their assertion seems, on the following accounts, to be better founded.

311. 'A sharp-pointed conductor, it is true, will attract electricity from a greater distance than one with an obtuse point, but at the same time will attract and conduct it very gradually, or rather by a continued stream, in which manner a remarkably small conductor is capable of conducting a very great quantity of electricity; whereas an obtusely terminated conductor attracts the electricity in a full separate body, or explosion, by which it is often made red-hot, melted, and even exploded in smoke, and by such a quantity of electricity as perhaps would not have at all affected it, if it had been sharply pointed.

312. 'A sharp-pointed conductor certainly invites the matter of lightning easier than an obtuse one; but to invite, receive, and conduct it in small quantities, never endangers the conductor; and the object of fixing a conductor to a house, is to protect the house from the effects of, and not the conductor from transmitting the lightning.

313. 'It is an observation much in favor of sharp-pointed conductors, that such steeples of churches, and edifices in general, as are terminated by pointed metallic ornaments, have very seldom been known to be struck by lightning; whereas others that have flat terminations and have a great quantity of metal in a manner insulated on the tops, are often struck; and it is but seldom that they escape without great damage.

314. 'Besides these considerations, a sharp-pointed conductor, by the same property of attracting electricity more readily than an obtusely terminated one, may prevent a stroke of lightning, which the latter is incapable of doing.

315. 'A conductor, therefore, to guard a building, as it is now commonly used, should, from several considerations and experiments, consist of one iron rod about three quarters of an inch thick, fastened to the wall of the building, not by iron cramps, but by pieces of wood. If this conductor were quite detached from the building, and supported by wooden posts at

the distance of one or two feet from the wall, it would be much better for common edifices, but it is more particularly advisable for powder-magazines, powder-mills, and all such buildings as contain combustibles ready to take fire. The upper end of the conductor should be terminated in a pyramidal form, with the edges, as well as the point, very sharp: and if the conductor be of iron, it should be gilt, or painted, for two or three feet. This sharp end should be elevated above the highest part of the building (as above a stack of chimneys, to which it may be fastened) at least five or six feet. The lower end should go five or six feet into the ground, and in a direction leading from the foundation; or it would be better to connect it with the nearest piece of water, if any be at hand. If this conductor, on account of the difficulty of adapting it to the form of the building, cannot conveniently be made of one rod, then care should be taken, that where the pieces meet, they be made to come in as perfect a contact with one another as possible; for, as we observed before, electricity finds considerable obstruction where the conductor is interrupted.

316. 'For an edifice of a moderate size, one conductor of the kind already described, is perhaps sufficient; but, in order to secure a large building from sustaining any damage by lightning, there should be two, three, or more conductors, in proportion to the extent of the building.

317. 'In ships a chain has often been used for this purpose, which, on account of its pliableness, has been found very convenient, and easy to be managed among the rigging of the vessel; but, as the electricity finds a great obstruction in going through the several links, so that chains have been actually broken by the lightning, their use is now almost entirely laid aside; and, in their stead, copper wires a little thicker than a goose-quill have been substituted, and found to answer extremely well. One of these wires should be elevated two or three feet above the highest mast in the vessel; this should be continued down the mast, as far as the deck, where, by bending, it should be adapted to the surface of such parts, over which it may most conveniently be placed, and by continuing it down the side of the vessel, it should be always made to communicate with the water.'

318. M. Cavallo gives, with cordial approbation, the following extract from the earl of Stanhope's learned work on electricity:—As requisites for the proper construction of conducting rods for the preservation of buildings from the effects of lightning he directs, (1.) 'That the rods be made of such substances as are the best conductors of electricity. (2.) That the rods be uninterrupted and perfectly continuous. (3.) That they be of a sufficient thickness. (4.) That they be perfectly connected with the common stock. (5.) That the upper extremity of the rods be as acutely pointed as possible. (6.) That it be very finely tapered. (7.) That it be prominent. (8.) That each rod be carried in the shortest convenient direction, from the point at its upper end to the common stock. (9.) That there be neither large nor prominent bodies of metal upon the top of the building proposed to be secured, but such as are connected with the conductor by some proper metallic communication. (10.) That there be a sufficient number of high and pointed rods: and, (11.) That every part of the building be very substantially erected.'

319. For the purpose of illustrating the principle on which the thunder-rod acts, there are some very satisfactory experiments generally employed by lecturers on electricity, which it may be proper here to explain, and before doing which we would just observe, that the charge used on these occasions should be moderate, having found from experience that, in that part of the experiments which is intended to show the effect of interruptions in the conductor, a strong charge has injured the apparatus.

320. The simplest form in which these experiments are made is that known by the name of the *thunder-house*. This is represented by fig 10, where A is a board about three-quarters of an inch thick, and shaped like the gable end of a house. It is fixed perpendicularly upon the bottom board B, upon which the perpendicular glass pillar C D is also fixed, in a hole about eight inches distant from the base of the board A. A square hole, I L M K, about a quarter of an inch deep, and nearly one inch wide, is made in the board A, and is filled with a square piece of wood, nearly of the same dimensions. This board must fit in rather easily, so that the slightest shaking may throw it out. A wire, L K, is fastened diagonally to this square piece of wood. Another wire, I H, of the same thickness, having a brass ball, H, screwed on its pointed extremity, is fastened upon the board A; so also is the wire M N, which is formed into a hook at O. From the upper extremity of the glass pillar, C D, a crooked wire proceeds, having a spring socket F, through which a double-knobbed wire slides perpendicularly, the lower knob G of which falls just above the knob H. The glass pillar D C must not be fixed very tightly into the bottom board; but it must be fixed so as to be pretty easily moved round its own axis, by which means the brass ball G may be brought nearer or farther from the ball H, without touching the part of E F G. When the square piece of wood L M I K, is fixed into the hole so that the wire L K stands in the dotted representation I M, then the metallic communication from H to O is continuous, and the instrument represents a house furnished with a proper metallic conductor; but if the square piece of wood L M I K is fixed so that the wire L K stands in the direction L K, as represented in the figure, then the metallic conductor H O, from the top of the house to its bottom, is interrupted at I M, in which case the house is not properly secured.

320.* Fix the piece of wood, L M I K, so that its wire may be as represented in the figure, in which case the metallic conductor H O is discontinued. Let the ball G be fixed at about half an inch perpendicular distance from the ball H, then, by turning the glass pillar D C, remove the former ball from the latter; by means of a chain connect the wire E F with the wire Q of the jar P, and let another chain, fastened to the hook O, touch the outside coating of the jar. Connect the wire Q with the prime conductor,

and charge the jar; then, by turning the glass pillar D C, let the ball G come gradually near the ball H, and when they are arrived sufficiently near one another, the jar will explode, and the piece of wood, L M I K, will be driven out of the hole to a considerable distance from the thunder-house. In this experiment the ball G represents an electrified cloud; which, when it is arrived sufficiently near the top of the house A, the electricity strikes it; and, as this house is not secured with a proper conductor, the explosion breaks part of it, as is seen by the violent removal of the piece of wood I M.

321. Repeat the experiment with only this variation, viz. that the piece of wood I M is situated so that the wire L K may stand in the direction I M, in which case the conductor H O is not discontinued; and then the explosion will have no effect upon the piece of wood L M, this remaining in the hole unmoved; which shows the usefulness of the metallic conductor.

322. Again, unscrew the brass ball H from the wire H I, so that this may remain pointed. With this difference only in the apparatus, repeat both the above experiments, and it will be found that the piece of wood I M is in neither case moved from its place, nor will any explosion be heard; which not only demonstrates the preference of the conductors with pointed terminations to those with obtuse ends; but also shows that a house furnished with sharp terminations, although not furnished with a regular conductor, is almost sufficiently guarded against the effects of lightning.

323. This apparatus is sometimes made in the shape of a house, as represented by fig. 11; for the sake of distinctness, the side and part of the gable end A C represents that of the thunder-house, and may be used in the same manner with that above described, or more readily by the following method:—Let one ball of the discharging rod touch the ball of the charged jar, and the other knob A of the conductor A C of the thunder-house; the jar will then explode, and the charge will act upon the conductor just mentioned. The conducting wire at the windows *h*, *h*, must be placed in a line. The sides and gable, A C, of the house, are connected with the lower part of the house by hinges, and the building is kept together by a ridge on the roof.

324. To use this model, fill the small tube *a* with gunpowder, and ram the wire *c* a little way into the tube; then connect the tube *c* with a large jar or battery. When the jar is charged, form a communication from the hook at C, on the outside, to the top of the jar, by the discharging rod; the discharge will fire the powder, and the explosion will throw off the roof, with the sides, back, and front, so that they will all fall down together. Fig. 12 represents a small ramrod for the tube *a*, and fig. 13 a pricker for the touch-hole at C. Philosophical and mathematical instrument makers now construct the front of the common thunder-houses as well as the powder-houses above described, with two pieces of wood or windows, which, by being placed in proper situations, the one to conduct and the other to resist the fluid, will illustrate by one discharge the usefulness of good conductors for securing buildings or magazines from the explosion of thunder, as well as the danger of using imperfect ones.

325. The most elegant method of performing this experiment, however, is represented in fig. 14, which exhibits a hollow pyramid of wood, composed of several pieces, having a wire through each, so that their ends may come in contact with each other, as seen at *s*, *s*, *s*. One corner of the pyramid must be made loose as shown at *d*, having the conducting wire passing nearly through it, but not quite so. The wire, passing through the rest of the pyramid, must join (by a chain) the outside coating of a Leyden jar. If the cloud *x* be supported by a wire from the prime conductor, and hang half an inch from the knob *g* of the pyramid; when the jar is charged, a flash will take place between *x* and *g*; the fluid will pass along the wires *s*, *s*, *s*, till it comes to the break at *d*; there an explosion will take place, that will force out the corner piece *d*, and throw down the fabric in separate pieces.

326. The preceding experiments sufficiently illustrate the use of conductors raised on buildings that are much exposed to the effects of thunder-storms; but, that we may not omit any information on the subject that may be deemed useful, we shall just add Mr. Morgan's method of preventing all possible danger in these cases. The plan which Mr. Morgan proposes is that, whilst a house is being built, the foundation of each partition wall should be laid on a strip of lead, or that the strip be fastened to the sides of these partition walls. The strips should be two inches wide, and at least a quarter of an inch thick, and closely connected with each other. A perpendicular strip, on each side of the house, should rise from the conductors to the surface of the ground; whence a strip should be continued round the house, and carefully connected with water-pipes, &c. The strips on the sides of the house should then be continued to the roof, which ought to be guarded in the same manner as the foundation. The top should be surrounded by a strip, which should be connected with every edge and prominence, and be continued to the summit of each separate chimney. It is particularly necessary to guard the chimneys; for Mr. Morgan mentions a case, in which a house that had been guarded in most respects, according to the preceding directions, except that the chimneys were unprotected, was struck with lightning, which entered by one of the chimneys: here it spent its fury; but the chimney falling on the roof, did considerable damage. The principal objection to this method is the expense attending it; but this may be in a great measure avoided, by making proper use of the leaden pipes, gutters, and copings, which belong to most houses.

327. Before leaving the subject of conducting rods, we think it due to the ingenious professor Leslie of the University of Edinburgh, to notice an article on electrical theories, published by him in the Edinburgh Philosophical Journal for July, 1824. In this paper Mr. Leslie endeavours to show that thunder-rods are of no use whatever in the way of protecting buildings against the

effects of lightning. But lest we should in any degree misrepresent the professor's sentiments, by giving an abridged statement of them, we shall quote his own words :—

328. 'But, whatever speculations we may form in regard to electrical light, and the mode in which the point and the knob produce their different effects, we must admit that the electricity is never communicated, in any perceptible degree, to a remote and unconnected body, but by means of a current of air; and this established principle will enable us to estimate the real effects of conductors or thunder-rods.

329. 'When two portions of air, near the point of saturation, and of different temperatures, are mixed, a quantity of the dissolved vapor is precipitated, and resumes its aqueous state. By this conversion the mass acquires electricity; and the consequent repulsion exerted, tends to disperse the minute globules of water, which will float in the atmosphere, or rather, will descend with that slow motion which is sufficient to occasion a resistance on their large surface equal to their gravitation. If the cloud thus generated reach the ground, it will soon communicate its electricity. If it be suspended at some height, the electrified air will stream from it in all directions; and if its formation be gradual, this discharge may suffice to waste its force. But when a vast cloud is suddenly formed, the aërial emission hardly impairs its electricity; and, as it is carried along, it continually approaches, by its attraction, to the surface, which assumes an opposite electricity; the air now rushes with violence, and the cloud bends faster downwards, till at last its lowest verge reaches the ground, and a total discharge is made. The magnitude of the stroke will evidently depend on the extent of the aqueous mass, the suddenness of its precipitation, and the rapidity of its descent.

330. 'The air, which streams in all directions from the cloud, is dissipated among the more remote portions, and thus gradually communicates its electricity. Hence, from the wide dispersion, owing to the distance, the electricity of the air at the surface of the earth must be weak; and, even in the midst of the storm, the electrometer is less affected than if placed only a yard behind the prime conductor. Yet the action of the thunder-rod is confined entirely to the air which immediately surrounds it, and the quantity of aërial current which it can produce, must evidently be inferior to what is directed to the point, when held several feet from the conductor of an electrical machine. But, to avert the stroke, it would be necessary that the whole air between the surface and the cloud should be brought successively in contact with the top of the rod. Nor is this all; for the air will be constantly replaced by other electrified portions emitted from the cloud. The effect of the thunder-rod is therefore, comparatively, but a drop in the ocean. It may be easily shown that, however pointed and tapered, it would require 1000 years to guard at the distance of 100 yards; if terminated with a knob, it may take 10,000 years. Such are the vaunted performances of thunder-rods, and such the advantages of their different forms! Nor can we appeal to experience; it never can be proved that thunder-rods have produced beneficial effects, but several instances may be cited where they have afforded no sort of protection Nay, we shall be convinced, that fully an equal proportion of the buildings armed with such supposed safeguards have been struck with lightning. But if thunder-rods are useless, they are also innocent; and, that they provoke the shaft of heaven, is the suggestion of superstition rather than of science. The cloud exerts an attraction, indeed, upon the surface of the ground, but the force depends solely on the distance, and is not, in the least degree, affected by the shape or quality of the substances below. It rolls towards the nearest and most elevated objects, and strikes indiscriminately a rock, a tree, or a spire.

331. 'If a thunder-rod be then a harmless, though idle, appendage to a house, why awaken uneasy apprehensions? It might at least inspire confidence in the moment of danger; and if happiness consists merely in idea, why not indulge delicious error?—Yet, though the inevitable stroke cannot be turned aside, its destructive effects may be lessened; and an investigation of the real action of thunder will conduct us to the proper principles.'—*Ed. Phil. Jour.* No. XXI. pp. 25. 28.

332. The above theory is certainly ingenious and worthy of attention, but it wants confirmation in another way than that attempted by its author. We would, with all deference to Mr. Leslie's well-known abilities, ask if he would advise large fires to be kept up round powder magazines for the purpose of preventing them from being struck by lightning? We do not know, either, why *he* advises that they should have copper conductors raised near them? nor why, to save ships, ribands of copper should be extended from the masts to the keel, since he affirms that the idea of *diverting* or dissipating the storm is *wholly chimerical.*

### Spontaneous Electricity of the Atmosphere.

333. Very numerous are the observations which have at different times been made by able observers on this branch of atmospherical electricity. We cannot here enter minutely into these, and shall therefore only offer an outline of their general results.

334. The earliest observations of this nature appear to have been those of Monnier; his experiments were made with an apparatus, which consisted of a pole thirty-two feet in height, insulated in a piece of turf, having at its top a strong glass tube, to which a tube of tinned iron was attached, and which terminated in a point. About the middle of this tube there was fastened a fine iron wire about fifty lines long, which, without touching any other body, was connected with a silk cord stretched horizontally. He found although the atmosphere was constantly electrified more or less, yet that in dry weather the electricity increased from sun-rise, when it was weakest, till about four o'clock in the afternoon, at which time it was strongest, gradually diminishing from that time till the dew began to fall, after which it diminished till midnight. The

same results were afterwards obtained by Saussure and Beccaria.

335. The abbé Mazeas made several observations with an atmospherical apparatus, consisting of an iron wire 370 feet long, raised about ninety feet from the ground, and properly insulated. The results of his experiments with this instrument were the following:—In very dry weather the wire readily attracted light bodies, if brought within three or four lines of it; and, if the weather was not stormy, the electricity of the air was about half as great as that of a stick of sealing-wax two inches long. When he grasped the wire in his hand, the signs of electricity disappeared entirely, and did not return till after an interval of three or four minutes. He also found that the electricity of the atmosphere was not increased with storms and hurricanes unattended with rain; for during a violent storm of wind, which continued uninterruptedly for three days, in the month of July, he found it necessary to place the dust within four or five lines of the conductor, before it exhibited a sensible attraction. No change was produced by the different directions of the winds. In the driest nights of summer he never could observe any electricity in the air, but it began to appear in the morning at sunrise, and vanished in the evening at about half an hour after sun-set. In the month of July, in a very dry day, when the sky was serene, and the heat intense, he found the electricity stronger than he had ever observed it. The dust was then attracted at the distance of ten or twelve lines from the conductor.

336. Mr. Kinnersley made several observations on the electricity of the atmosphere in its ordinary state, and informs us that when the air was very dry, he found it always contained some electricity, and that he rendered this electricity visible by electrifying himself negatively, and holding in his hand a long sharp needle, which, in the dark, appeared luminous at the point.

337. Beccaria, who was particularly attentive to this subject, and made numerous experiments both with rods and kites, found that, during the three following states of the atmosphere, it afforded no sensible indications of electricity. (1.) When the weather was clear, but at the same time windy. (2.) When the sky was covered with well defined black clouds, moving slowly. (3.) During moist weather, when not actually raining. The electricity was always perceptible when the sky was clear and the weather calm; in rainy weather, and when it did not lighten, the electricity appeared always a little before the rain fell, continued during the falling of the rain, and disappeared shortly after the rain ceased. The higher he raised his rods, the stronger he found these electrical signs.

338. M. de Saussure, however, has furnished us with the most extensive course of experiments on atmospherical electricity. He informs us that it is constantly varying, according to situation. It is generally strongest in elevated and insulated situations, not to be observed under trees, in streets, in houses, or any enclosed places, though it is sometimes to be found pretty strong on quays and bridges. It is also not so much affected by the absolute height of the places as their situation; thus a projecting angle of a high hill will often exhibit a stronger electricity than the plain at the top of the hill, as there are fewer points than in the former to deprive the air of its electricity. This variation in the intensity of the electricity of the atmosphere, seems influenced by numerous circumstances, some of which it is difficult satisfactorily to account for.

339. When the weather is not serene, it is impossible to assign any rule for their variation, as no regular correspondence can then be perceived with the different hours of the day, nor with the various modifications of the air. The reason is evident; when contrary and variable winds reign at different heights, when clouds are rolling over clouds, these winds and clouds, which we cannot perceive by any exterior sign, do, nevertheless, influence the strata of air in which we make our experiments, and produce these changes of which we only see the result, without being able to assign either the cause or its relation. Thus, in stormy weather, we find the electricity strong, then completely gone, and in a moment after rise to its former force; one instant positive, the next negative, without being able to assign any reason for these changes.

340. M. Saussure says, that he had known these changes succeed with such rapidity, that he had not time to note them down. When rain falls without a storm these changes are not so sudden; they are, however, very irregular, particularly with respect to intensity of force; the quality of them, too, is more constant. Rain or snow almost uniformly gives positive electricity. In cloudy weather, without rain or storms, the electricity follows generally the same laws as in serene weather. Strong winds generally diminish its intensity; they seem to mingle together the different strata of the atmosphere, and make them pass successively towards the ground, and thus distribute the electricity uniformly between the earth and the air. M. Saussure has observed a strong electricity with a strong north wind. The state of the air in which the electricity is strongest is foggy weather; this is also accompanied with electricity, except when the fog is going to resolve into rain.

341. The most interesting observations, and those which throw the greatest light upon the various modifications of electricity in our atmosphere, are those made in serene weather. In winter, and in serene weather, the electricity is generally weakest in the evening, when the dew has fallen, until sun-rising; its intensity afterwards augments by degrees, sometimes sooner and sometimes later; but generally before noon, it attains a certain maximum, whence it again declines, till the fall of the dew, when it will be sometimes stronger than it had been during the whole day; after which, it will again gradually diminish during the whole night; but, it is never quite destroyed, if the weather is perfectly serene. Atmospherical electricity seems, therefore, like the sea, to be subject to a flux and reflux, which causes it to increase and diminish twice in twenty-four hours. The times of its greatest force are some hours after the rising and setting of the sun: those when it is weakest precede these periods.

342. M. Saussure has given an instance of this periodic flux in electricity. On the 22nd of Feb. 1785, one of the coldest days ever remembered at Geneva, the hygrometer and thermometer were suspended in the open air on a terrace exposed to the south-west; the electrometer, from its situation, indicated an electricity equal to what it would have shown if it had been placed on an open plain. The height of the barometer was reduced to what it would have been if the mercury had been constantly at the temperature of 10° of Reaumur's thermometer. The place of observation was elevated sixty feet above the level of the lake. The observations of the day preceding and following this great cold were registered by him. There was a weak south-west wind during the whole three days; and it is rather remarkable, that most of the great colds, which have been observed at Geneva, were preceded by, or at least accompanied with, a little south-west breeze. From the first eighteen observations made during these three days, when the sky was quite serene, we learn that the electricity was pretty strong at nine o'clock A. M.; that from thence it gradually diminished till towards six o'clock P. M., which was its first minimum; after which it increased till eight o'clock, its second maximum; from whence it gradually declined till six the next morning, which was the time of its second minimum; after which, it again increased till ten in the morning, which was the first maximum of the following day; as this was cloudy, the periods were not so regular.

343. As we have hitherto but slightly noticed the method of exploring the atmosphere by the electrical kite, we shall here introduce an account of an experiment of this kind made by Mr. Cavallo, which is, in every respect, most gratifying and satisfactory; at least, it will be viewed in this light by every real lover of the science of electricity; and will, at the same time, read him a most useful lesson on the caution to be observed in making this boldest of all electrical experiments. It must be observed, that this experiment was made when there was no thunder; and that there had been none for three days before, nor did there happen to be any for three days after at the place where the scene occurred.

344. 'After,' says Mr. Cavallo, 'having rained a great deal in the morning and night before, the weather became a little clear in the afternoon, the clouds appearing separated, and pretty well defined. The wind was west, and rather strong, and the atmosphere in a temperate degree of heat. In these circumstances, at 3 P. M., I raised my electrical kite with 360 feet of string. After that the end of the string had been insulated, and a leather ball, covered with tin-foil, had been hung to it, I tried the power and quality of the electricity, which appeared to be positive and pretty strong.

345. 'In a short time, a small cloud passing over, the electricity increased a little; but the cloud being gone, it decreased again to its former degree. The string of the kite was now fastened by the silk lace to a post in the yard of the house in which I lived, which was situated near Islington, and I was repeatedly charging two coated phials, and giving shocks with them. While I was so doing, the electricity, which was still positive, began to decrease, and in two or three minutes' time it became so weak, that it could be hardly perceived with a very sensible cork-ball electrometer. Observing at the same time that a large and black cloud was approaching the zenith (which, no doubt, caused the decrease of the electricity), indicating imminent rain, I introduced the end of the string through a window, in a first-floor room, in which I fastened it by the silk lace to an old chair. The quadrant electrometer was set upon the same window, and was, by means of a wire, connected with the string of the kite.

346. 'It being now three-quarters of an hour after three o'clock, the electricity was absolutely unperceivable; however, in about three minutes time, it became again perceivable, but now upon trial was found to be negative; it is therefore plain, that its stopping was nothing more than a change from positive to negative, which was evidently occasioned by the approach of the cloud, part of which by this time had reached the zenith of the kite, and the rain also had begun to fall in large drops. The cloud came farther on, the rain increased, and, the electricity keeping pace with it, the electrometer soon arrived to 15°. Seeing now that the electricity was pretty strong, I began again to charge the two coated phials, and to give shocks with them; but the phials had not been charged above three or four times, before I perceived that the index of the electrometer was arrived at 35°, and was keeping still increasing. The shocks now being very smart, I desisted from charging the phials any longer; and, considering the rapid advance of the electricity, thought to take off the insulation of the string, in case that if it should increase farther it might be silently conducted to the earth, without causing any accident, by being accumulated in the insulated string.

347. To effect this, as I had no proper apparatus near me, I thought to remove the silk lace, and fasten the string itself to the chair; accordingly I disengaged the wire that connected the electrometer with the string, laid hold of the string, untied it from the silk lace, and fastened it to the chair; but while I effected this, which took up less than half a minute of time, I received about a dozen or fifteen very strong shocks, which I felt all along my arms, in my breast and legs, shaking me in such a manner, that I had hardly power enough to effect my purpose, and to warn the people in the room to keep their distance. As soon as I took my hands off the string, the electricity (in consequence of the chair being a bad conductor) began to snap between the string and the shutter of the window, which was the nearest body to it. The snappings, which were audible at a good distance out of the room, seemed first isochronous with the shocks which I had received, but in about a minute's time oftener; so that the people of the house compared their sound to the rattling noise of a jack going when the fly is off.

348. The cloud now was just over the kite; it was black, and well defined, of almost a cir-

cular form, its diameter appearing to be about 40°; the rain was copious, but not remarkably heavy. As the cloud was going off, the electrical snapping began to weaken, and in a short time became inaudible. I went then near the string, and finding the electricity weak, but still negative, I insulated it again, thinking to keep the kite up some time longer; but observing that another larger and denser cloud was approaching apace towards the zenith, as I had then no proper apparatus at hand, to prevent every possible accident, I resolved to pull the kite in; accordingly a gentleman who was by me began pulling it in, while I was winding up the string. The cloud was now very nearly over the kite, and the gentleman, who was pulling in the string, told me that he had received one or two slight shocks in his arms, and that if he were to feel one more, he would certainly let the string go; upon which I laid hold of the string, and pulled the kite in as fast as I could, without any farther observation, being then ten minutes after four o'clock.'

349. Mr. Cavallo, from the numerous experiments which he made with electrical kites, lays down the following results, which will be found correct in the generality of cases. (1.) 'The air appears to be electrified at all times; its electricity is constantly positive, and much stronger in frosty than in warm weather; but it is by no means less in the night than in the day-time. (2.) The presence of the clouds generally lessens the elasticity of the kite; sometimes it has no effect upon it; and it is very seldom that it increases it a little. To this the above-mentioned instance is a most remarkable exception. (3.) When it rains, the electricity of the kite is generally negative, and very seldom positive. (4.) The aurora borealis seems not to affect the electricity of the kite. (5.) The electric spark taken from the string of the kite, or from any insulated conductor connected with it, especially when it does not rain, is very seldom longer than a quarter of an inch; but it is exceedingly pungent. When the index of the electrometer is not higher than 20° the person who takes the spark will feel the effect of it in his legs; it appearing more like the dischage of an electric jar, than the spark taken from the prime conductor of an electrical machine. (6.) The electricity of the kite is generally stronger or weaker, according as the string is longer or shorter; but it does not keep any exact proportion to it. The electricity, for instance, brought down by a string of 100 yards, may raise the index of the electrometer to twenty, when, with double that length of string, the index of the electrometer will not go higher than twenty-five. (7.) When the weather is damp, and the electricity is pretty strong, the index of the electrometer, after taking a spark from the string, or presenting the knob of a coated phial to it, rises surprisingly quick to its usual place; but in dry and warm weather it rises very slowly. (8.) The principal use of the electrical kite is to show the electricity of the atmosphere; and it is perhaps the only instrument that will do this at all times with certainty, though several others have been invented for that purpose. But another use to which electrical kites have been applied, is to bring down quantities of the electric fluid from the upper regions of the atmosphere, for the purpose of supplying that deficiency of electricity, which is supposed to be hurtful to vegetation.'

350. From numerous experiments on the spontaneous electricity of the atmosphere made by Mr. Read, he has drawn the following conclusions:—(1.) 'That in moderate weather it is uniformly positive, and experiences an increase and a decrease in the degree of its intensity twice in twenty-four hours. (2.) That the electricity is strongest about two or three hours after sun-rise, and some time both before and after sun-set; and is in general in the weakest state between noon and four o'clock. (3.) And that this periodical electricity is obviously influenced by heat and cold.'

351. The latest experiments that have been made on this subject, on a large scale, are those by Andrew Crosse, Esq. of Broomfield, near Taunton. They were made by means of an apparatus the most extensive ever constructed. It consisted of a copper wire, one-sixteenth of an inch in thickness, stretched and insulated between two strong upright poles measuring from 100 to 110 feet in height.

352. No pains was spared to render this apparatus the most extensive and perfect that has been constructed. The insulated wire was one mile and a quarter in length, but having been exposed to various depredations, and liable to injury from other causes, it was shortened to 1800 feet. Every contrivance was tried to insulate this wire, but Mr. Crosse could not succeed in preserving the insulation during a dense fog, or a driving snow. A contrivance was adopted to lower the insulators, for the purpose of freeing them from spiders' webs; and it was necessary to fix the wire very securely, in order that it might be able to resist the weight of the great numbers of swallows that often perched upon it, and of wood-pigeons and owls that flew against it with considerable force. This apparatus has been in use for some years, and has enabled Mr. Crosse to draw the following conclusions, which confirm the observations of preceding authors.

353. (1.) 'The electricity is invariably positive during the usual state of the atmosphere, and subject to a regular increase and decrease, as stated in some of the preceding observations.

354. (2.) 'Fogs, rain, snow, hail, and sleet, produce changes in the electrical state of the wire. The electricity is negative when they first appear. It frequently changes to positive, increasing gradually in strength; and then decreasing in a similar manner, and changing from positive to negative every three or four minutes. Those phenomena have been so constantly observed, that, whenever the wire appears negatively electrified, it is considered as a certain indication, that either rain, snow, hail, mist, or a thunder-cloud, is approaching.

355. (3.) 'The approach of a charged cloud at first is sometimes found to produce positive, and sometimes negative electricity; but, whatever be the kind of the electricity which first appears, its intensity increases to a certain degree, then diminishes, and finally disappears, and is suc-

ceeded by the opposite electricity; which increases to a higher degree than the first had done; it then diminishes, and vanishes, and is again succeeded by the electricity which first appeared. These alternations of positive and negative electricity are often exceedingly numerous, and on different occasions succeed one another with different degrees of rapidity. The electricity, in general, becomes more intense at every repetition, till a copious and dense stream of sparks issues from the atmospherical conductor to the receiving-ball, stopping at intervals, and returning with redoubled force.

356. (4.) 'In this state of things, a strong current of air flows from the wire, and the apparatus with which it is connected. At every flash of lightning an explosive stream, attended by a very peculiar noise, passes between the balls and the apparatus, and brilliantly illuminates the surrounding objects, while the effects on the spectator are heightened by the successive peals of thunder, and the consciousness of being so near their cause.

357. 'When the electricity becomes too powerful to allow the observer to operate in safety, he connects the insulating wire with the ground; along this the whole passes off silently and harmlessly to the ground.

358. (5.) 'During a driving fog, or a smart rain, the wire is electrified almost as powerfully as during a thunder-storm, and the electricity exhibits similar changes.

359. (6.) 'A weak positive electricity generally prevails in cloudy weather. It often changes to negative when rain falls; but the positive electricity re-appears when the rain has ceased to fall.

360. (7.) 'The electricity is always stronger in clear frosty weather than during a fine summer's day.'

361. The following table, drawn up by Mr. Crosse, exhibits the intensity of the electrical appearances of the atmosphere in different states, commencing with those in which it is most powerful:—

(1.) During the occurrence of regular thunder clouds.

(2.) A driving fog, accompanied by small rain.

(3.) A fall of snow, or a brisk hail-storm.

(4.) A smart shower, especially in a hot day.

(5.) Hot weather succeeding a series of wet days.

(6.) Wet weather following a series of dry days.

(7.) Clear frosty weather, either in the night or day.

(8.) Clear warm summer weather.

(9.) A sky obscured by clouds.

(10.) A mackerel back, or mottled sky.

(11.) Sultry weather, the sky covered with light hazy clouds.

(12.) A cold damp night.

362. For common purposes, and occasional observations, Mr. Singer says, very simple contrivances may be employed. A common jointed fishing-rod, having a glass stick covered with sealing-wax substituted for the smallest joint, may be occasionally projected from the upper window of a house. A pair of pith-balls must be attached to a cork, in which the end of the glass stick is thrust; and this part of the apparatus is to be occasionally uninsulated, by placing a pin in the cork, connected with a thin wire held in the hand. In this uninsulated state, the fishing-rod and its attached electrometer are to be held for a few seconds projecting from the window, and, whilst in this position, the pin is to be withdrawn by pulling the thin wire; this insulates the electrometer, which may be then drawn in and examined. Its electricity will be found to be contrary to that of the atmosphere.

363. The last circumstance which we shall notice respecting the electricity of the atmosphere, is its effects on the vegetable kingdom. Much has been said relative to the merits of the question, whether the electricity of the atmosphere has or has not an influence on the process of vegetation. It is remarkable that this should ever for one moment have been matter of doubt with any one, since it is well known that light and heat, and, in one word, the free access of the air of our atmosphere, are all essential to the general process of vegetation. Where difficulties have occurred in the course of experiment on the subject, we are firmly persuaded that they relate entirely to the management of the apparatus employed; we can readily manage the regulations of warming, watering, and airing a small house, in which we wish to accelerate the growth of vegetable substances; but when we attempt to take, as it were, the management of the atmosphere in our own hands, and to regulate the general process of vegetation in our fields or gardens, we must expect to meet that disappointment which is ever attendant on quitting the sphere of action allotted to mortals. No series of experiments, how nicely soever conducted, can ever be expected to equal the silent, the invisible, but unerring operations of nature.

364. The first electrician who seems to have attended to this subject was Mr. Maimbray of Edinburgh, who, in the year 1746, electrified two myrtles, during the whole month of October, for some hours every day. The consequence was, that, in the following summer, these electrified myrtles put forth buds and blossoms sooner than those which had been left to nature.

365. Mr. Maimbray was followed by the abbé Nollet, who made some comparative experiments on the germination of seeds under similar circumstances, except that one plot was electrified three or four hours every day during the space of fifteen days. His experiments were attended with results similar to those obtained by Mr. Maimbray.

366. Experiments of a similar nature were repeated by others, and, as was to be expected, were in general followed by the like results. Hence the effect of electricity in promoting vegetation became universally acknowledged, till a series of well-conducted experiments, made by Dr. Ingenhousz, staggered the faith of philosophers in general on the subject

367. Several electricians, however, labored hard to support the credit of the abbé Nollet's system, although but with little success. Among these, the chief was the abbé Bertholon, who wrote a work which was entirely confined to the subject. The reasoning of this author, however incorrect it may appear to many, has certainly

the recommendation of ingenuity; and, although he carried his notions relative to the effects of electrical influence much farther than most are desirous of doing, we cannot perceive why these circumstances should be considered, as they have been by some, as the ground of ridicule.

368. But that our readers may form their own judgment on this subject, we shall here introduce the abbé's own account of the instrument with which his experiments were chiefly made, and of his method of procedure.

369. M. Bertholon commences his account by observing that there is continually and universally diffused in the atmosphere, and particularly in the higher regions, a considerable quantity of the electric fluid. 'This principle,' says he, 'being granted; in order to remedy the deficiency of electric fluid, which is supposed hurtful to vegetation, we must erect on the spot which we want to fecundate the following new apparatus, which has had all possible success, and which I shall call by the name of the electro-vegetometer. This machine is as simple in its construction as efficacious in its manner of acting; and I doubt not but it will be adopted by all those who are sufficiently instructed in the great principles of nature.'

370. The apparatus which the abbé here denominates his electro-vegetometer, consists of a mast or long pole firmly fixed into the ground to be able to resist the force of the wind; at the upper extremity of this pole is fixed a wire which terminates in one or more points, for the purpose of collecting the electricity of the air, and with which is connected a long insulated conductor, terminating in five or six points directed to the ground.

371. After having described at great length the construction of this apparatus, he proceeds to observe.—'The construction of this electro-vegetometer once well understood, it will be easy for us to conceive its effects. The electricity which prevails in the aërial regions will soon be drawn down by the elevated points of the upper extremity. This effect of the points is proved by the most decisive experiments, and is called by philosophers the power of the points.

372. 'By means of the electro-vegetometer just now described, one may be able to accumulate at pleasure this wonderful fluid, however diffused in the regions above, and conduct it to the surface of the earth, in those seasons when it is either scantily supplied, or its quantity is insufficient for vegetation, or, although it may be in some degree sufficient, yet it can never produce the effects of a multiplied and highly increased vegetation. So that by these means we shall have an excellent vegetable manure or nourishment, brought down as it were, from heaven, and that, too, at an easy expense; for, after the construction of this instrument, it will cost nothing to maintain it: it will be, moreover, the most efficacious you can employ; no other substance being so active, penetrating, or conducive to the germination, growth, multiplication, or reproduction, of vegetables. This heavenly manure is that which nature employs over the whole habitable earth, not excepting even those regions which are esteemed barren, but which, however, are often fecundated by those agents which nature knows so well to employ to the most useful purposes. Perhaps there was nothing wanting to bring to a completion the useful discoveries that have been made in electricity, but to show this so advantageous an art of employing electricity as a manure.

373. 'Consequently, that all the effects which we have already mentioned depend upon electricity alone; and, lastly, that all these effects, viz. acceleration in the germination, the growth, and production of leaves, flowers, fruit, and their multiplication, &c., will be produced even at a time when secondary causes are against it; and all this is brought about by the electric fluid, which we have the art of accumulating over certain portions of the earth, where we want to raise those plants that are most calculated for our use.

374. 'By multiplying these instruments, which are provided at little expense (since iron rods, of the thickness of one's finger, and even less, are sufficient for the purpose), we multiply their beneficial effects, and extend their use ad infinitum.

375. 'This apparatus having been raised with care in the midst of a garden, the happiest effects were perceived, viz. different plants, herbs, and fruits, in greater forwardness than usual, more multiplied, and of better quality. These facts are analogous to an observation which I have often made, viz. that plants grow fast, and are most vigorous, near thunder-rods, where their situation favors their development. They likewise serve to explain why vegetation is so vigorous in lofty forests, and where the trees raise their heads far from the surface of the earth, so that they seek, as it were, the electric fluid at a far greater height than plants less elevated; while the sharp extremities of their leaves, boughs, and branches, serve as so many points granted them by the munificent hand of nature, to draw down from the atmosphere that electric fluid which is so powerful an agent in forwarding vegetation, and in promoting the different functions of plants.'

376. It may be proper here to add, that others who succeeded Bertholon in his experiments, and with all his experience at their service, do not seem to have thrown any light on the subject. M. Achard, of Berlin, tried the effects of electricity on a small quantity of fermented rye, which was intended for distillation. He electrified one-half of it; and after five hours the vinous fermentation had ceased in the electrified portion, while in that which was not so treated it did not cease till after the lapse of eight hours. He then tried the effect of strong sparks upon a quantity of rye; which, excepting in one case, which he notices, he found to accelerate the process of fermentation.

### Miscellaneous Experiments, &c.

377. *Illuminated phosphorus*, or the Bolognian stone. Among the numerous methods devised for exhibiting the effects of electrical light, perhaps the most curious is that made with the real, or more easily with the artificial Bolognian stone, or Canton's phosphorus. This phosphorus

is a calcareous substance, generally used in the form of a powder, which has the property of absorbing light when exposed to it, and afterwards appearing lucid when brought into the dark. Take some of this powder, and, by means of spirits of wine or ether, stick it all over the inside of a clear glass phial, and stop it with a glass stopper, or a cork and sealing-wax. If kept in a room perfectly darkened, it will give no light; but let two or three sparks be drawn from the prime conductor, when the phial is kept at about two inches from the sparks, so that it may be exposed to that light, and this phial will receive that light, and afterwards will appear illuminated for a considerable time. The powder may be stuck upon a board by the white of an egg, so as to represent figures of planets, letters, or any thing else; and these may be illuminated in the dark, in the same manner as the phial. A beautiful method to express geometrical figures with the above phosphorus, is to bend small glass tubes of about the tenth part of an inch diameter, in the shape and figure desired, and then fill them with the phosphoric powder. These may be illuminated in the manner described, and they are not so subject to be spoiled as the figures represented upon the board frequently are. The best method of illuminating this phosphorus, and which Mr. W. Canton generally used, is to discharge a small electric jar near it.

378. *The tourmalin.*—The tourmalin, or the *lapis electricus* of Linnæus, is a hard semi-pellucid fossil, and was first observed to exhibit electrical phenomena, on being heated and cooled. This stone is found in abundance in the East Indies, and is named the electrical stone from its possessing many singular electrical properties. The properties of this stone seem to have been known to the ancients: Theophrastus mentions a stone which he terms the *lyncurium*, and describes it as being very hard; susceptible of a high polish, very useful for making seals, &c.; and possessing the property of attracting light substances. Hence there can be little doubt as to its being the tourmalin of the moderns. The Dutch seem to have discovered the properties of the tourmalin by observing that when placed in the fire it attracted the ashes; hence they gave it the name of aschen-trikker.

379. But by increasing its heat it becomes electrical, and still more so by diminishing it. Its electricity appears, not over its whole surface, but only on two opposite sides, which have been styled its poles, as they are in a line with its centre, and in the same direction with its strata; in which direction it is opaque, though semi-transparent in the other.

380. During the process of heating, the tourmalin has one of its sides electrified positively, and the other negatively; but, while cooling, the former becomes negative and the latter positive. If heated and allowed to cool without either side being touched, the former will be positive and the latter negative, all the time it is heating or cooling. If excited by rubbing, each of its sides, or both at once may be rendered positive. I heated or cooled upon an insulated substance that substance will become possessed of the electricity contrary to that of the side of the tourmalin, which was laid on it. The electricity of both sides, or of either, may be reversed by heating or cooling the stone, in contact with other bodies.

381. If a tourmalin be cut in pieces, each piece will have its positive and negative poles, as well as the whole stone. All the above properties are observable in vacuo. If this stone be covered over with wax, oil, or any similar electric, it will exhibit the same electric signs as without the covering.

382. In making experiments with the tourmalin, Mr. Canton observed a vivid light upon it, while heating in the dark, by which he could determine which end of the tourmalin was positive or negative. When excited, it emits very strong flashes in the dark, from the positive to the negative end. Mr. Canton has also observed the Brasilian emerald emit light while heating in the dark. Mr. Cavallo 'imagines that every other precious stone will show it if its electric power be sufficiently strong; since the light is a consequence of the passage of a sufficient quantity of electricity through the air, or other partly resisting medium.'

383. The electrical power of the tourmalin is sometimes improved, sometimes injured, sometimes not in the least affected by a strong fire. Most of the above properties, which were supposed to be peculiar to the tourmalin, are possessed by several hard precious stones, which are capable of becoming electrical by heating and cooling, and have their positive and negative sides lying in the direction of their strata, &c.

384. *Evaporation produces electricity.*—This appears to have been a discovery of Signor Volta, who observed that the evaporation of water and some other fluids, as well as certain effervescences, generated electricity. His experiments seem to prove that fluids, or other bodies, reduced to vapor, become electrified positively, and leave the bodies from which they evaporated, electrified negatively; and that on the other hand, when the vapors are condensed into a fluid, they become electrified negatively, and leave the bodies with which they were last in contact electrified positively.

385. The common method of illustrating this is the following:—Place on the cap of a gold-leaf electrometer a metallic dish containing a few lighted coals, and project on them a few drops of water, whilst an insulated funnel is held about a foot or eighteen inches above. Under these circumstances the electrometer is found to be negatively electrified, and the insulated funnel positively. On this experiment Mr. Walker observes, that the vapor carries off the latent electricity from the electrometer; the leaves diverge, and fly to the slips of tin-foil to supply their loss. He adds, perhaps the vapor derives its volatility from its union with electricity, for it is observable, that if insulated pith-balls be suspended in a fog or mist, they separate spontaneously with positive electricity.

386. *To electrify the air of a room.*—This is an experiment which may be easily performed with a powerful machine. The room ought to be very clean, and as free as possible from

pointed metallic substances. These things being observed, place a few pointed wires in the prime conductor of the machine; put the machine in action, and after the lapse of a few minutes the air of the room will become so impregnated with electricity as to be very perceptible to the sense of smelling, and will readily affect a delicate electrometer, particularly if brought into the vicinity of the machine. The odor perceived on this occasion very much resembles that of oxygen gas, or of the atmospheric air in a very clear and frosty night.

387. *The charge of a jar is retained in the electric.*—This is proved in a very satisfactory manner by the following experiments, which show that the coating of the Leyden jar has not quite so much to do with the charge as is generally supposed. The first is given by Mr. Walker in his System of Familiar Philosophy, and is in substance as follows:—Lay a plate of tin or brass on your hand, and on it a plate of glass (rather larger than the metallic plate); on the glass lay another metallic plate, and let this communicate with the prime conductor: thus the glass may be charged. By the edge of the glass disengage it from the two plates, and place two other plates in the same situation, upon and under the glass. If now one knob of the discharging-rod be made to touch the under plate, and the other knob the upper plate, a discharge will ensue the same as if the first plates had remained in their place.

388. The same principle is thus illustrated by the Leyden jar; we give the process as directed by Mr. Singer:—Procure a jar with a double set of moveable tin-coatings, either of which may be adapted to it at pleasure; the outer coating being a tin can large enough to admit the jar easily within it; and the inner coating a similar can sufficiently small to pass readily in the inside of the jar. The charging wire of the inner coating should be surrounded by a glass tube covered with sealing-wax, to serve as an insulating handle, by which the inner coating may be lifted from the jar when that is charged, without communicating a shock to the operator. Arrange the jar with its coatings, and charge it; it will act in every respect as an ordinary coated jar. Charge the jar, and, without discharging it, remove the inner coating by its insulating handle; if this coating, when removed, be examined, it will be found not at all, or but slightly electrified: lift the jar carefully from within its outer coating, and examine that; it will evince no signs of electricity.

389. Let the jar be now fitted up with the other pair of moveable coatings; apply the discharger, and an explosion and spark will follow, which clearly proves that the accumulation is retained by the attractive power of the glass, and that the coatings are only useful as conductors to the charge.

390. *Velocity of the electric fluid.*—Although we have already made some passing remarks on this subject, the following detail will, we doubt not, be found interesting to the admirers of the electrical science. Several electricians of distinguished merit have made experiments on the velocity of the electric fluid; those to which we here particularly refer were made under the direction and superintendence of Mr. Watson, who, as an eye-witness of them, drew up the account to lay before the Royal Society.

391. The first attempt of these electricians was to convey electric shocks across the river Thames, availing themselves of the water of the river as one part of the circuit through which the charge was to pass. This they accomplished on the 14th and 18th of July, 1747, by fastening a wire all along Westminster-bridge, at a considerable height above the water. One end of this wire communicated with the coating of a charged phial, the other being held by an observer, who, in his other hand, held an iron rod, which he dipped into the river. On the opposite side of the river stood a gentleman, who likewise dipped an iron rod in the river with one hand; and in the other held a wire, the extremity of which might be brought into contact with the wire of the phial.

392. When the discharge was made, the shock was distinctly felt by the observers on both sides of the river, but more sensibly by those who were stationed on the same side with the machine; part of the electric fire having gone from the wire down the moist stones of the bridge thereby making several shorter circuits to the phial, but still all passing through the gentlemen who were stationed on the same side with the machine. This was, in a manner, demonstrated by some persons feeling a sensible shock in their arms and feet, who only happened to touch the wire at the time of one of the discharges, when they were standing upon the wet steps which led to the river. In one of the discharges made upon this occasion, spirits were kindled by the fire which had gone through the river. The gentlemen made use of wires in preference to chains, as communicating a stronger degree of electricity.

393. Their next attempt was to cause the electrical fluid to make a circuit of two miles, at the New River at Stoke Newington. This they performed on the 24th of July, 1747, at two places; at one of which the distance by land was 800 feet, and by water 2000: in the other, the distance by land was 2800 feet, and by water 8000. The disposition of the apparatus was similar to what they had before used at Westminster-bridge, and the effect answered their utmost expectations. But as, in both cases, the observers at both extremities of the chain, which terminated in the water, felt the shock as well when they stood with their rods fixed into the earth twenty feet from the water, as when they were put into the river; it occasioned a doubt, whether the electric circuit was formed through the windings of the river, or a much shorter way, by the ground of the meadow; for the experiment plainly showed that the meadow-ground, with the grass on it, conducted the electricity very well.

394. From subsequent experiments they were fully convinced that the electricity had not in this case been conveyed by the water of the river, which was two miles in length, but by land where the distance was only one mile; in which space, however, the electric matter must neces-

sarily have passed over the New River twice, and have gone through several gravel-pits, and a large stubble-field.

395. On the 28th of July, they repeated the experiment at the same place, with the following variation of circumstances:—The iron wire was, in its whole length, supported by dry sticks, and the observers stood upon original electrics; the effect was, that they felt the shock much more sensibly than when the conducting-wire had lain upon the ground, and when the observers had likewise stood upon the ground, as in the former experiment. Afterwards, every thing else remaining as before, the observers were directed, instead of dipping their rods into the water, to put them into the ground, each 150 feet from the water. They were both smartly struck, though they were distant from each other above 500 feet.

396. Their next object was to determine whether the electric virtue could be conveyed through dry ground; and, at the same time, to carry it through water to a greater distance than they had done before. For this purpose they pitched upon Highbury Barn, beyond Islington, where they carried it into execution on the 5th of August, 1747. They chose a station for their machine almost equally distant from two other stations, for observers upon the New River, which were somewhat more than a mile asunder by land, and two miles by water.

397. They had found the streets of London, when dry, to conduct very strongly for about forty yards; and the dry road at Newington about the same distance. The event of this trial answered their expectations. The electric fire made the circuit of the water, when both the wires and the observers were supported upon original electrics, and the rods dipped into the river. They also both felt the shock, when one of the observers was placed in a dry gravelly pit, about 300 yards nearer the machine than the former station, and 100 yards distant from the river: from which the gentlemen were satisfied, that the dry gravelly ground had conducted the electricity as strongly as water.

398. From the shocks which the observers received, when the electric power was conducted upon dry sticks, they were of opinion, that, from the difference of distance simply considered, the force of the shock, as far as they had yet experienced, was very little if at all impaired. When they stood upon electrics, and touched the water on the ground with the iron rods, the shock was always felt in their arms or wrists; when they stood upon the ground, with their iron rods, they felt the shock in their elbows, wrists, and ankles; and, when they stood upon the ground without rods, the shock was always felt in the elbow and wrist of that hand which held the conducting wire, and in both ankles.

399. The last investigation which these gentlemen made on this subject, and which required all their sagacity and address in the conduct of it, was to try whether the electric shock was perceptible at twice the distance to which they had before carried it, in ground perfectly dry, and where no water was near; and also to distinguish, if possible, the respective velocity of electricity and sound. For this purpose they fixed upon Shooter's Hill, and made their first experiments on the 14th of August, 1747; a time when, as it happened, but one shower of rain had fallen during five preceding weeks. The wire communicating with the iron rod which made the discharge, was 6732 feet in length, and was supported all the way upon baked sticks: as was also the wire which communicated with the coating of the phial which was 3868 feet long, and the observers were distant from each other two miles.

400. The result of the explosion demonstrated to the satisfaction of the gentlemen present, that the circuit performed by the electric matter was four miles, viz. two miles of wire and two of dry ground, the space between the extremities of the wires; a distance which, without trial, as they justly observed, was too great to be credited. A gun was discharged at the instant of the explosion and the observers had stop-watches in their hands, to note the moment when they felt the shock: but as far as they could distinguish, the time in which the electric matter performed that vast circuit might have been instantaneous. In all the explosions where the circuit was made of considerable length, it was observed that though the phial was very well charged, yet that the snap at the gun barrel, made by the explosion was not near so loud as when the circuit was formed in a room: so that a by-stander, says Dr. Watson, though versed in these operations, would not imagine from seeing the flash, and hearing the report that the stroke at the extremity of the conducting wire could have been considerable; the contrary whereof, when the wires were properly managed, he says, always happened.

401. Still, these philosophers were desirous to ascertain the absolute velocity of electricity at a certain distance; because though in the last experiment, the time of its progress was certainly very small, if any, they were desirous of knowing, small as that time might be, whether it was measurable: and Dr. Watson had contrived an excellent method for that purpose. Accordingly, on the 5th of August, 1748, the gentlemen met once more at Shooter's Hill; when it was agreed to make an electric circuit of two miles, by several turnings of the wire in the same field. The middle of this circuit they contrived to be in the same room with the machine, where an observer took in each hand one of the extremities of the wires, each of which was a mile in length. In this excellent disposition of the apparatus, in which the time between the explosion, and the shock might have been observed to the greatest exactness, the phial was discharged several times; but the observer always felt himself shocked at the very instant of making the explosion. Upon this the gentlemen were fully satisfied, that through the whole length of this wire, which was 12,276 feet, the velocity of the electric matter was instantaneous.

402. Notwithstanding all this surprising velocity, it is certain, that both sides of a charged phial may be touched so quickly, even by the best conductors, that all the electric matter had not time to make the circuit, and the phial will

remain but half discharged. If the upper plate of an electrophorus also is very suddenly touched with the finger, or any other conductor, a very small spark will be obtained on lifting it up; though a very strong one would be got if the finger was kept longer upon it. But how this seeming slowness can be reconciled with the immeasurable velocity above mentioned, does not appear. It is certain, indeed, that this fluid is considerably resisted in its passages through or over every substance. It will even prefer a short passage in the air where it is violently resisted to one along a wire of very great length; but here, as in every other case, it seems to divide its force, and to break through several different passages at once.

403. The amazing velocity of the electric fluid has recently given rise to some speculations on the subject of constructing electrical telegraphs; this idea, however, appears altogether chimerical, as has been proved by some experiments made by professor Barlow, of the Royal Military Academy. By employing wires of different lengths up to 840 feet, and measuring the energy of the electric action by the deflection produced in the magnetic needle, he found that the intensity rapidly diminishes, and very nearly as the inverse square of the distance. Mr. Barlow also ascertained that the effect was greater with a wire of a certain size than with a finer one; but at the same time, that no advantage was gained by increasing the diameter beyond a certain limit.

404. We have thus gone through what we consider as the essentials of electricity in general; we have omitted several things which we consider as being now obsolete, and some also that are of too trifling a nature to deserve a place in any work pretending to respectability. It has been our aim to produce the most useful information on every part of the subject, and to give the whole as much interest and life as the nature of a subject, purely philosophical, would admit. It may, however, be adviseable, prior to closing the present article, to furnish our readers with the latest facts in the science of electricity, and many that follow are discoveries that are due to the period that we are now writing.

### On Paratonnerres, or Conductors of Lightning.

405. A very interesting report on the subject of paratonnerres, has been presented to the Royal Academy of Sciences by M. Gay Lussac. The paper is divided into two parts; one theoretical, and the other practical, and the information contained in it may be regarded as the most perfect we possess on the subject.

406. The theoretical part is introduced with some general observations on electric matter, and of conductors; that its velocity is at the rate of about 1950 feet per second; that it penetrates bodies, and traverses their substance, with unequal degrees of velocity; that the resistance of a conductor increases with its length, and may exceed that which would be offered by a worse but shorter conductor; and that conductors of small diameter conduct worse than those of larger. The electric matter also tends always to spread itself over conductors, and to assume a state of equilibrium in them, and becomes divided among them in proportion to their form, and principally to their extent of surface; and that hence a body that is charged with the fluid being in communication with the immense surface of the earth, will retain no sensible portion of it.

407. Gay Lussac defines a paratonnerre to be a conductor which the electric matter prefers to the surrounding bodies, in order to reach the ground, and expand itself through it; and commonly consists of a bar of iron elevated on the buildings it is intended to protect, and descends without any divisions or breaks in its length, into water or moist ground. When a paratonnerre has any breaks in it, or is not in perfect communication with a moist soil, the lightning, having struck it, flies from it to some neighbouring body, or divides itself between the two, in order to pass more rapidly into the earth.

408. The most advantageous form that can be given to the extremity of a paratonnerre is that of a sharp cone, and the higher it is elevated in the air, other circumstances being equal, the more its efficacy will be increased, as is proved by the experiments of M.M. de Romas and Charles.

409. It has not been accurately ascertained how far the sphere of action of a paratonnerre extends; but, in several instances, the more remote parts of large buildings on which they have been erected, have been struck by lightning at the distance of three or four times the length of the conductor from the rod. According, however, to the opinion of Charles, a paratonnerre will effectually protect from lightning a circular space, whose radius is twice that of the height of the conductor. By increasing, therefore, the altitude of a conductor, the space also which it will protect is augmented in proportion.

410. A current of electric matter, whether luminous or not, is always accompanied by heat, the intensity of which depends on the velocity of the current. This heat is sufficient to make a metallic wire red hot, or to fuse or disperse it, if sufficiently thin; and hence we may perceive the absurdity of some attempts which have been lately made, to protect ships, by thin slips of copper nailed to the masts. The heat of the electric fluid scarcely raises the temperature of a bar of metal, on account of its large mass; and no instance has yet occurred of an iron bar, of rather more than half an inch square, or of a cylinder of the same diameter, having been fused, or even heated red hot by lightning. A rod of this size would, therefore, be sufficient for a paratonnerre; but, as its stem should rise from fifteen to thirty feet above the building, it would not be of sufficient strength at the base to resist the action of the wind, unless it were made much thicker at that part. An iron bar, about three-quarters of an inch. is sufficient for the conductor of the paratonnerre.

411. According to Gay Lussac, a paratonnerre consists of two parts, the stem which projects in the air above the roof, and the conductor,

which descends from the foot of the stem to the ground. The stem he proposes to be a square bar of iron, tapering from its base to the summit, in form of a pyramid, and for a height of from twenty to thirty feet, which is the mean length of the stems placed on large buildings; the base should be about two inches and a half square. Iron being very liable to rust by the action of air and moisture, the point of the stem would soon become blunt; and therefore, to prevent it, a portion of the top, about twenty inches in length, should be composed of a conical stem of brass or copper, gilt at its extremity, or terminated by a small platina needle, two inches long. Instead of the platina needle, one of standard silver may be substituted, composed of nine parts of silver, and one of copper. The platina needle should be soldered with a silver solder to the copper stem; and to prevent its separating from it, which might sometimes happen, notwithstanding the solder, it should be secured by a small collar of copper. The copper stem is united to the iron one, by means of a gudgeon, which screws into each; the gudgeon is first fixed in the copper stem by two steady pins at right angles to each other, and is then screwed into the iron stem, and secured there also by a steady pin.

412. The conductor should be about three-quarters of an inch square, and, as before stated, reach from the foot of the stem to the ground. It should be firmly united to the stem, by being tightly jammed between the two ears of a collar, by means of a bolt. The conductor should be supported parallel to the roof, at about six inches distance from it, by forked stanchions, and after turning over the cornice of the building, without touching it, should be brought down the wall, and to which it should be fastened by means of cramps. At the bottom of the wall, it is bent at right angles, and carried in that direction twelve or fifteen feet, when it turns down into a well.

413. Since iron buried in the ground in immediate contact with moist earth soon becomes covered with rust, and is by degrees destroyed, the conductor should be placed in a trough filled with charcoal, in the following manner. Having made a trench in the earth, about two feet deep, a row of bricks is laid on their broad faces, and on them others on edge; a stratum of bakers' ashes (braise de boulanger) is then strewed over the bottom bricks, about two inches thick, on which the conductor is laid, and the trough then filled up with more ashes, and closed by a row of bricks laid along the top. Iron thus buried in charcoal, will undergo no change in thirty years. After leaving the trough, the conductor passes through the side of the well before alluded to, and descends into the water to the depth of at least two feet below the lowest water line. The extremity of the conductor usually terminates in two or three branches, to give a readier passage to the lightning into the water. If there be no well at hand, a hole must be made in the ground, with a six-inch auger, to the depth of about ten or fifteen feet, and the conductor passed to the bottom of it, placing it carefully in the centre of the hole, which is then to be filled up with bakers' ashes, rammed down as hard as possible, all round the conductor. In a dry soil, or on a rock, the trench to receive the conductor should be at least twice as long as that for a common soil, and even longer, if thereby it be possible to reach moist ground. Should the situation not admit of the trench being much increased in length, others, in a transverse direction, should be made, in which small bars of iron, surrounded by ashes, are placed and connected with the conductor. In general, the trench should be made in the dampest, and consequently lowest spot near the building, and the water gutters made to discharge their waters over it, so as to keep it always moist. Too great precautions cannot be taken to give the lightning a ready passage to the ground, for it is chiefly on this that the efficacy of a paratonnerre depends.

414. As iron bars are difficult to bend according to the projections of a building, it has been proposed to substitute metallic ropes in their stead. Fifteen iron wires are twisted together, to form one strand, and four of these form a rope, about an inch in diameter. To prevent its rusting, each strand is well tarred, separately, and, after they are twisted together, the whole rope is tarred over again with great care. Copper or brass wire is, however, a better material for their construction than iron. If a building contain any large masses of metal, as sheets of copper or lead on the roof, metal pipes and gutters, iron braces, &c., they must all be connected with the paratonnerre, by iron bars of about half an inch square, or something less. Without this precaution, the lightning might strike from the conductor to the metal (especially if there should be any accidental break in the former), and occasion very serious injury to the building, and danger to its inhabitants.

415. *Paratonnerres for Churches.*—For a tower, the stem of the paratonnerre should rise from fifteen to twenty-four feet, according to its area; the domes and steeples of churches, being usually much higher than the surrounding objects, do not require so high a conductor as buildings with extensive flat roofs. For the former, therefore, their stems, rising from three to six feet above the cross or weather-cock, will be sufficient, and being light they may easily be fixed to them without injuring their appearance, or interfering with the motion of the vane.

416. *Paratonnerres for Powder-Magazines.*—These require to be constructed with the greatest care. They should not be placed on the buildings, but on poles at from six to ten feet distance. The stems should be about seven feet long, and the poles of such a height, that the stem may rise from fifteen to twenty feet above the top of the building. It is also advisable to have several paratonnerres round each magazine. If the magazine be in a tower, or other very lofty building, it may be sufficient to defend it by a double copper conductor, without any paratonnerre stem. As the influence of this conductor will not extend beyond the building, it cannot attract the lightning from a distance, and will yet protect the magazine, should it be struck.

417. *Paratonnerres for Ships.*—The stem of a paratonnerre for a ship, consists merely of a

copper point, screwed on a round iron rod, entering the extremity of the top-gallant mast. An iron bar, connected with the foot of the round rod, descends down the pole, and is terminated by a crook or ring, to which the conductor of the paratonnerre is attached, which, in this case, is formed of a metallic rope, connected at its lower extremity with a bar or plate of metal, and which latter is connected to the copper sheathing on the bottom of the vessel. Small vessels require only one paratonnerre; large ships should have one on the main-mast and another on the mizen-mast.

418. The late ingenious Mr. George Singer, in his excellent work on electricity, proposed to have conductors fixed to the surfaces of masts, and the electric fluid conveyed by means of strips of metal, over the deck and the sides of the vessel; but this arrangement on many accounts is highly objectionable, and the mode proposed by Gay Lussac, or perhaps that commonly adopted in the British navy, of conveying the electric fluid from the mast-head to the surface of the water, in a direct line, by means of a series of long copper links, is the best which has hitherto been devised.

419. It is allowed from experiment, that the stem of a paratonnerre effectually defends a circle of which it is the centre, and whose radius is twice its own height. According to this rule, a building sixty-feet square, requires only a stem of fifteen or eighteen feet raised in the centre of the roof. A building of 120 feet, by the same rule, would require a stem of thirty feet, and such are sometimes used; but it is better, instead of one stem of that length, to erect two of fifteen or eighteen feet, one placed at thirty feet from one end of the building, the other at the same distance from the other end, and consequently sixty feet from each other. The same rule should be followed for three or any greater number of paratonnerres. A plate is given in the Annals of Philosophy to illustrate this interesting subject more particularly.

### Electro-motive Action of Water on Metals.

420. M. Becquerel has endeavoured to ascertain experimentally the electrical effects produced by the contact of water and metals. The effect is so small as to be easily mistaken for, or confounded with, those due to electricity produced accidentally during the performance of the experiments, by contact of various parts of the apparatus, or in other ways: but taking every possible precaution, and testing his results in all ways, he arrived at the conclusion that zinc, iron, lead, tin, copper, &c., communicated positive electricity to water; whilst platina, gold, silver, &c., gave it negative electricity. Water is therefore positive with the metals which are most positive, and negative with those which are least positive. It operates, therefore, upon oxidable metals as alkalies do in their conduct with acids, when there is no chemical action. The same phenomena take place even when a little sulphuric acid is present, and the iron and zinc are acted upon, so that chemical action in this case did not prevent the production of electricity by the contact of metals and water

421. By certain changes of the surface, it was found that the intensity of electricity produced was much affected. A plate of gold, plunged in nitric acid for a few moments, and then washed in several fresh portions of water, produced a development of electricity much greater than before, the water still becoming negative. The same plate, plunged into a solution of potassa and then washed, lost in a great measure its power of becoming electrified by contact with water. A plate of platinum offered similar results. It is supposed, that these effects may have a distant analogy with the facts observed by M. M. Thenard and Dulong, that a new platina wire, which would not heat in a current of hydrogen gas and air, acquired this property by being previously plunged for a few minutes in nitric acid, and then washed. The property of the wire continued for above twenty-four hours; and M. Becquerel says, that the plate of gold preserved its power of becoming strongly electrified in contact with water, for several hours.

### On the Electrical Actions produced by the Contact of Flames and Metals.

422. In place of making a complete metallic circuit, as in Seebeck's experiment; or one in which the circuit was by water or acid, as in the Voltaic pile; the metals used were connected by a flame only, and their states ascertained by the electrometer. The flames used were those resulting from the combustion of alcohol, hydrogen gas, or a sheet of paper. When a plate of platina was placed on the cap of the electrometer, and heated by one of the flames before mentioned, if the temperature was a red heat or above, the metal became negative, but below a red heat it became positive. On trying the electricity of the flame, by making it rise from a piece of wet wood on the cap of the instrument, and holding the platina in it, the reverse, as expected, was found to be the case.

423. A copper wire gave the same results, and generally it appeared that all the metals had the property just described; thus any metal, plunged into a flame of hydrogen gas, becomes negative or positive according as the temperature is higher or lower, and communicates the contrary electricity to the flame.

424. If the flame by which the plate of metal on the cap of the instrument is heated, be touched by a piece of wet wood instead of being insulated, the effects are more distinct: but if, instead of touching it with wet wood, it be touched with a plate of the same metal as that on the electrometer, the two portions of metal are found in different states: that heated to redness being negative, and the one heated to a less degree positive. The same effects are obtained if the two plates be of different metals. They are also produced if the flame urged by a blow-pipe be used.

425. These phenomena may be supposed to result either from the friction of the flame on the metals, or from an electro-motive action. M. Becquerel inclines to the latter opinion, conceiving it improbable that the tranquil flame of alcohol can produce friction sufficient to suffice for the

effect; and not being able to account by friction for the circumstance of two pieces of metal acquiring different electricities in the same flame, according to the temperature. That the effect was not due to the difference of temperature existing in various parts of the same piece of metal, was proved by the entire absence of any electrical phenomena, when a plate of platinum was heated to redness in the focus of M. Fresnel's strong burning-glass. These experiments have some relation to that of M. Volta on the combustion of a piece of amadou at the extremity of a rod communicating with the condensing plate of an electrometer. M. Volta found, that when the apparatus was distant from habitations, the amadou became positive by taking electricity from the circumambient air, from which he concluded that the atmosphere had always an excess of positive electricity.

### Electrical Phenomena accompanying Combustion.

426. M. Becquerel found, that on rolling up a sheet of paper, placing it in the electrometer, inflaming it, and touching the flame with a piece of wet wood that the electricity might flow away more rapidly, the paper became positively electrical. If the experiment were inverted, the paper being held in the hand, and the flame made to touch the piece of wet wood placed on the electrometer, it was found that the flame took negative electricity. Hence it may be concluded, that when paper is burnt, the paper becomes positive, and the flame negative.

427. If alcohol be burnt in a copper capsule, it is found by the condenser that the capsule becomes electrified positively.

### On the Electro-motive Force of certain Substances.

428. *Carburet of iron.*—In electro-motive power it yields only to certain oxides of manganese. It is augmented by immersion into acidulated water, if the plate be not wiped when withdrawn. This increase of power is not dissipated spontaneously, but is easily lost by the action of an inferior metal, as zinc. When the latter action diminishes that belonging to the carburet, it is resumed spontaneously in a few minutes. The Passau crucibles contain much plumbago, and possess the same properties if the clay has not been too much vitrified; a crucible having an internal surface of 100 square inches, and a vessel of similar form made of thin lead, produced a very useful apparatus.. A small interval was left between the leaden vessel and the crucible, and the interval filled with a strong acid solution. By heating the crucible, and cooling the interior of the leaden vessel, important effects, dependent upon the difference of temperature, could be observed.

429. *Mercury.*—This metal ranges between sulphuret of lead and silver; when impure it becomes inferior even to brass, but distillation restores it to its place.

430. *Iron.*—Its electro-motive power is changed by oxidation, but not much. Its place is always between tin and brass.

431. *Tin* is superior to lead, but the least degree of oxidation renders it inferior. *Lead,* with zinc, gives greater deviations than tin, iron, brass, or copper. There is no arrangement formed with substances so near to each other, which produces so energetic a current, and it is in this respect opposed to that presented by zinc, with gold or platina.

432. *Charcoal,* heated until it ceases to yield flame and slowly cooled, is equal to the metals in electro-motive and conducting power. It does not retard the feeblest electric current. Its electro-motive power is variable, according to the manner in which it is cooled, and also to its exposure to air.

433. *Oxide of tin,* crystallised, produces currents, with all the metals inferior to it, as zinc, lead, tin, &c.; but none when in communication with bodies having a superior electro-motive force, as gold, silver, carburet of iron, gray manganese, &c.—*Annales de Chimie,* XXXIII., 136.

434. List of good conductors, arranged in the order of their electro-motive power, the most powerful being first.

Charcoal after long exposure to air.
Gray radiated manganese.
Oxide of manganese.
Uncrystallised iron pyrites.
Magnetic iron pyrites.
Crystallised arsenical pyrites
Carburet of iron.
Cubic iron pyrites.
Auriferous tellurium.
Gold.
Platina.
Copper pyrites.
Lamelliform tellurium.
Gray cobalt.
Gray copper ore.
Arsenical nickel.
Charcoal slowly cooled.
Sulphureted protoxide of iron.
Sulphuret of lead.
Red silver ore (bright).
Arsenical silver, and arsenic slightly oxidised.
Mercury.
Silver.
Tarnished antimony.
Arsenic.
Sulphuret of molybdena.
Crystallised oxide of tin.
Tarnished copper.
Antimony (bright).
Charcoal extinguished in water.
Nickel.
Tarnished bismuth.
Brass much oxidised.
Bright copper.
Brass.
Crystallised protoxide of iron.
Iron.
Tarnished lead.
Manganese.
Tin.
Bright lead.
Charcoal, instantly after extinction in water.
Zinc.

### Insulation of Electricity.

435. M. Haüy, in his method of distinguishing precious stones, &c., joins the electric indications given by a gem when rubbed or pressed to its other physical characters. That these indications may be obtained more readily, M. Haüy has invented two small instruments, very portable, and ready to furnish the two kinds of electricity. One of them is a small bar of Iceland spar, fixed to the end of a needle or lever, which is then suspended by the middle so as to be balanced by a thread of silk. When the spar is pressed between the fingers, it becomes positively electric, and then the electricity of another body, however excited, as of a gem by friction, is ascertained by its attraction or repulsion of the spar. The second instrument is formed of a piece of sealing-wax, flattened at one end so that it may stand on a table, and at the other supporting the point of a needle; a needle of silver or copper, terminated at the extremities by beads, moves on this as on a centre. To charge this apparatus, a piece of amber or sealing-wax is to be excited negatively by friction, and then by touching the needle it becomes similarly electrified, and is then ready to indicate by attraction or repulsion the kind of electricity possessed by another body.

436. M. Haüy has also noticed the extreme permanency of the electrical states of these two apparatuses. His attention was drawn to this circumstance, from the perfection of their action during extremely moist weather, and he was induced to make a few experiments on the subject. The permanency of the electricity excited on the spar depends on the difficulty of adhesion between it and water. In damp weather no moisture deposits on it, so that electricity given to it is perfectly retained. Even if it be dipped in water, and afterwards pressed without wiping, it becomes strongly electric, because no water adheres to its surface to conduct the power away; and M. Haüy at last ascertained that immersion in water was not sufficient to remove electricity previously communicated to it. The permanency, therefore, of its electrical state in the atmosphere, and the value of this property may easily be conceived. If the water be rubbed on the surface of the crystal so as actually to wet it, then no electricity is generated by pressure, and what may have previously been generated is of course dissipated.

437. M. Haüy has observed also, that fluate of lime and the euclax also acquired electricity by pressure, though not so powerfully as Iceland spar; and he found them also to possess similar relations to water.

438. During his experiments on the electricity of minerals, M. Haüy found that the second apparatus also had the power of preserving its electric state unimpaired for a long time; a circumstance scarcely to be expected from its construction. In examining the apparatus, this power was found to depend on the sealing-wax foot, for if that were removed and the needle hung by silk, though it readily took electricity from other bodies, yet it also soon lost it; whereas, on its pivot and foot of sealing-wax, it retained it in damp weather for hours. This appears to depend on a portion of electricity, which, when the needle is first charged, passes on to the surface of the sealing-wax, and, remaining there for a while, gradually returns to the needle, as its state is reduced by the action of the moist air, and supports, as it were, its electricity at a higher tension than it otherwise would have. M. Haüy expresses this by saying that the sealing-wax has the power both of conducting and insulating; by the first it receives a part of the electricity given to the needle, by the second it retains it, and then by the first it gives it back again to the needle when the air has taken away its own portion. The evident conclusion from the experiments is, that the apparatus is always ready for use, and will act in any weather.

### Plate Electrical Machines.

439. A variation in the construction of plate electrical machines has been devised and practiced by M. Metzger, of Siblingen, in Schaffhouse, which seems to be a real improvement. Considering that the effect desired in using the machine was first highly to excite the glass, and then to collect the electricity from it, M. Metzger concluded that the distance between the rubber and the points of the conductor, in machines of the common construction, was injurious in its effects, not only by causing the dispersion in part of the electricity excited, but by uselessly wasting the exciting surface. Plates were, therefore, mounted in a very compact and perfect manner, with three pairs of rubbers, placed at equal distances from each other; the conductor also had three arms furnished with points a little in advance of each pair of rubbers, to collect the electricity in the usual manner; and the rubbers were not attached to a surrounding frame, but to brass arms, which, proceeding from a socket through which the axis passes, diverged at equal distances from each other towards the periphery of the plate: the machine has a very compact and neat appearance, and its various smaller parts are contrived with much judgment.

440. In some comparative experiments, made with a plate twenty-two inches in diameter, the superiority of three pairs of cushions over two pairs was very manifest. In the following table the first column expresses the length in inches of the rubbers; the second the length of the spark when two pairs of rubbers were used, and the third the length of the spark when three pairs of rubbers were on the machine.

| Inches. | Inches. | Inches |
|---|---|---|
| 6 | 12 | 18 |
| 7 | 14 | 21 |
| 8 | 16 | 24 |
| 9 | 18 | 27 |
| 10 | 20 | 30 |

### Experiment with a Tourmaline.

441. That the tourmaline possesses electrical properties dependent on its temperature has been long known: the most elegant mode, however, of exhibiting these phenomena has been suggested by Mr. Sivright. If a slice be cut from this mineral, perpendicular to the axis of the prism, and then placed upon a piece of well-polished glass, on being heated to a temperature of 212° it will be

found to adhere so firmly as to support the weight of the slice. The two poles of a tourmaline may also be connected in such a way as to exhibit the effects of attraction and repulsion. To effect which, the oppositely electrified poles are furnished with metallic caps and wires, resembling a horse-shoe magnet; and a light pith-ball, placed between these metallic conductors, is made to vibrate till the electric equilibrium is restored.

### Electricity of a Cat.

442. The electricity, upon rubbing the back of a cat, is well known; and that it is rendered evident by a snapping noise and sparks of light. Mr. Glover, in a letter to the editor of the Philosophical Magazine, describes so intense an action of this kind, as to enable the animal to give a very sensible electric shock. This effect was obtained at pleasure by Mr. Glover, and by some friends. When the cat was sitting on the lap of the person, if the left hand was placed under the throat with the middle finger and the thumb gently pressing the bones of the animal's shoulder, and the right hand was placed along the back, shocks were felt in the left hand; and when the right hand was placed under the throat, whilst the left hand rubbed the back, the shocks were felt in the right hand. When the atmosphere has been favorable, and the cat had lain some time before the fire, the experiment always succeeded.

### Bohnenbergen's Electrometer.

443. This instrument is intended to indicate at once the nature, as well as presence, of electricity. The exterior is formed of a cylinder of glass, about two inches and a half wide: it is closed at the top by a brass plate, from which descend two of De Luc's electric columns, each containing about 400 discs of gilt and silvered paper, about three lines in diameter, and terminated below by brass rings; these tubes are an inch and a half distant from one another, and between them is placed a tube of glass, which, passing through the cover, in the manner of Singer's insulation, supports a wire, terminated below by two gold leaves, and above by a metallic plate. It is easy, from this disposition, to perceive that when the leaves are unelectrified they will hang midway between the tubes; but when affected by the approach of electrified bodies, they will diverge and indicate by the attraction of the leaf on the one side, on the other the nature of the charge.

### Electricity produced by Congelation of Water.

444. When water is frozen rapidly in a Leyden jar, the outside coating not being insulated, the jar receives a feeble electrical charge, the inside being positive, the outside negative. If this ice be rapidly thawed, an inverse result is obtained, the interior becomes negative, and the outside, positive.—*Grothus.*

### Improvement of the Leyden Jar.

445. M. Metzger has varied the construction of Leyden jars, so as to augment their capacity without increasing their apparent volume. For this purpose, having two jars of proper dimensions, he simply places one within the other, so that they shall apply pretty correctly, and thus have a capacity of charge nearly proportional to the whole surface of coating, without increasing the volume of the whole beyond that of the larger jar. Jars made slightly conical would answer well for this purpose.

### Electricity on Separation of Parts.

446. In the water-proof cloths manufactured by M. Mackintosh of Glasgow, where two pieces are cemented together by caoutchouc dissolved in coal, tar, or oil, the adhesion is such, that when the two are torn asunder in the dark, there is a bright flash of electric light, similar to that produced by separating plates of mica, by breaking Rupert's drops, or by breaking barley-sugar, or sugar-candy. Upon trying this experiment with different substances, it was found that flashes of light were distinctly produced by tearing quickly a piece of cotton cloth.

### Electric Light.

447. Having a metallic wire covered with silk, form it into a close flat spiral, taking care that the revolutions touch each other: their number may be arbitrary, more than twenty-four have not been used. The properties of this spiral, when it forms part of the Voltaic circuit, are well known; but pass through it a charge of common electricity, such as may be taken by two square feet of coated surface, moderately charged, and a vivid light, something resembling that of an artificial fire-work, will occur, originating from the centre of the spires: it may be seen very distinctly without darkening the chamber where the experiment is made. M. Leopold de Nobili, who describes this experiment, considers the phenomenon as perfectly new. If the wire be folded backwards and forwards, so as to form a rectangular surface, then the electric discharge only produces a faint light at each corner, and this he considers as the light produced by the escape of the electricity into the atmosphere; but the light from the spiral is said to be so vivid and distinct, that once seen, its dissimilarity from the former must be instantly evident; he has therefore called it electro-magnetic light, because of its relation to the magnetic state of the spiral, thinks that it might be made continuous if a sufficiently powerful Voltaic battery were used, and has little doubt but that the aurora borealis is such a light, elicited by the magnetic state of the earth.

### Electricity excited by the Burning of Paper and Alcohol.

448. M. Becqueral has found, as the result of numerous experiments, that when a roll of paper is set on fire at one end, the flame thereof becomes negatively electrified, and the paper positively. He also found that when alcohol is burned in a copper dish, the latter becomes positively electrified.

### Hare's Single Gold-leaf Electrometer.

449. This instrument consists of a glass vessel, fixed by a foot to a wooden stand, and having an aperture at the top, and also another at one side. The top is closed by a metal cap,

finished externally by a horizontal zinc disc, six inches in diameter, and connected internally with a single leaf of gold, cut into an acute triangular form, and hanging on the centre of the instrument, with the point downwards. Opposite to the lower end of this leaf of gold, is a ball attached to a horizontal wire, and which, passing through a screw cap fixed in the lateral opening of the glass vessel, can be made to approach to, or recede from, the leaf at pleasure, the distance being estimated by a graduation of the screw into $\frac{1}{10}$ of an inch. A plate of copper, six inches in diameter, and furnished with a glass handle, generally accompanies the instrument.

450. The electricity produced by the contact of copper and zinc, is rendered sensible in the following manner:—Place the disc of copper on the disc of zinc; take the micrometer screw in one hand, touch the copper disc with the other, and then lift this disc from the zinc. As soon as the separation is effected, the gold leaf will strike the ball, usually if the one be not more than $\frac{1}{100}$ of an inch apart from the other. 'That the phenomenon arises from the dissimilarity of the metals, is easily shown by repeating the experiment with a zinc disc, in lieu of a disc of copper. The separation of the homogeneous discs will not be found to produce any contact between the leaf and the ball.'

451. 'It is probable that the sensibility of this instrument is dependent on that property of electricity which causes any surcharge of it, which may be created in a conducting surface, to seek an exit at the most projecting termination or point connected with the surface;' this disposition being increased, of course, by the proximity of the ball. These effects are not to be expected in weather unfavorable to electricity; but in favorable circumstances they have been produced by a smaller instrument, the discs being only two inches and a half in diameter.

### Pyro-Electricity of Minerals.

452. M. L'Abbé Haüy has remarked, with regard to the electricity produced in certain crystals by an alteration of temperature, that it is of two kinds. The accidental circumstances which led to the discovery took place whilst he was examining some crystals of the oxide of zinc, from Limbourg, near Aix-la-Chapelle, and fragments of the acicular variety of the same mineral from Brisgau. Having placed a piece of one of these substances in a very cold window for a few moments, it was found, on examination, to be electrical. Its poles were ascertained, and the mineral then placed in a milder temperature, when the electricity soon become null; but, being approached to a fire-place, the power was greatly renewed, but the poles were inverted.

453. These results have been verified by M. Haüy on other crystals, especially those of the tourmaline. In taking them for examples, he has endeavoured to bring under one point of view all that passes with respect to them in the interval comprised between the limits of temperature, beyond which the electric action disappears without return. He has given the name of ordinary electricity to that produced by heat, and extraordinary electricity to that produced by cold. If, therefore, commencing at the point where the excess of heat destroys in the tourmaline the effects of the ordinary electricity, that mineral be left to cool, it will soon give signs of ordinary electricity. The action of the poles at first feebly augments to a certain degree, beyond which it gradually diminishes, and at last disappears. With a temperature a little lower, however, the extraordinary electricity appears, and the poles resume their power, but in an inverted order, so that the pole at first positively electrified becomes negative, and the negative pole becomes positive.

### Electricity of the Atmosphere.

454. M. Bourdet, an ex-captain in the French service, has described in a letter, a very singular electric phenomenon which he witnessed in Poland, December 24th, 1826. The weather, according to the Poles, had never been milder at that season of the year, no snow had been seen, nor had the usual cold weather of the north, which generally set in early in that country, then commenced. Rains and storms, however, were frequent. 'I was,' says M. Bourdet, 'with the advanced guard of light cavalry; the commander gave me an order to halt in the rear and see that my guns were disembarrassed, and then to rejoin, as quickly as possible, the light brigade. In spite of the efforts of my men, the guns were not cleared from the marshy ground in which they were entangled, without great labor. We were advancing across the field about nine o'clock in the evening, when a strong gust of wind suddenly arose, the sun had shone brightly during the day, and, in a few minutes after, the night became so dark that we could not see the heads of our horses. The wind blew so violently that the horses stopped. At that moment the extremity of the hair on their ears became luminous, as well as all the longer hairs on their bodies except the locks on their manes and tails. All the metallic extremities of their harness, and all the metallic sharp points of the carriages of our guns, were studded with luminous points, so that one might have supposed, had it been spring, that a swarm of glow-worms had covered our horses and guns. Our quarter-master observed that the points of my mustachios were luminous. The same phenomenon was seen on some of the cannoneers, but none of us had our eye-lashes or hair rendered luminous. These lights remained as long as the gust of wind lasted, namely, for three or four minutes. Their color was a soft violet, and they terminated in a bright white. The horses held their heads high, their ears were erect and moving, their nostrils open and respiring, their manes and tails erected, their fore legs thrown forward and their hind ones back. Their attitude, in general, was that of animals seized with terror. During the time the wind blew, they remained at a full stop, and, when feeling the spur, some stood stock still, and others kicked, as if they had been reluctant to advance. When the wind ceased the lights disappeared, and a deluge of rain, mingled with hail, fell. But, though the obscurity continued, our horses moved on, shaking themselves at times, panting forcibly, and neighing; but they continued on their march. On arriving at the advanced post, I mentioned

to my comrades the phenomenon we had witnessed, and though they had been only three leagues from us, they felt no wind, but experienced much rain. The wind we encountered had an opposite direction to the rain.

### Relation of a remarkable electrical Phenomenon.

455. The following relation is made by M. Allemand, of Fleuvier Neufchatel, to M. Pictet, and is published in the Bib. Univer. M. Allemand, states that on the 3d of May, about ten o'clock in the evening was caught in a violent storm of wind and rain. The thunder becoming frequent and strong, he thought it proper to close an umbrella he had with him, and hold the upper metallic point in his hand, lest it should attract the lightning. The night, dark of itself, was made more so by the great rain. Suddenly he perceived a light from above, and looking upwards found the edge of his hat luminous. Supposing at the moment the hat was on fire, he, without reflection, passed his hand over the light to extinguish it. It, however, only shone more strongly, a circumstance which caused some confused ideas on the nature of the light. The hand being filled with water from the hat, on shaking it, M. Allemand saw that the interior of it shone as if it were a polished metal reflecting a strong light.

456. Being at this time near the farm of Chaux, about ten or twelve minutes' walk from Fleurin, and fifteen or twenty from Motiers, M. Allemand considered for a moment what he had best do, and concluded on continuing his progress. Having once filled his hand with the electrified water with impunity, he ventured to repeat the experiment, and did it fifteen or twenty times, endeavouring to ascertain whether it had odor, or produced any decrepitation or sound; but nothing of this kind could be perceived; nothing but the bright light, which seemed like a brilliant varnish on the hand. The light remained for an instant only. At a few hundred paces farther on, the light on the hat still continuing, M. Allemand was surprised by the appearance of another light, less bright than the former, on the smooth surface of the umbrella handle, at the place where generally a plate of metal is placed for the name, but which plate had been removed from this umbrella. At first the finger was passed over it to extinguish it, but the phenomena were just as before, and both the rubbing and rubbed surface shone brightly. Afraid of the metal about the umbrella, it was thrown down, and M. Allemand went on his way, rubbing his hat on the sleeve of his coat; but in this way only rendering the light brighter. The thunder was more frequent than before, but still at some little distance. The crown of light continued until M. Allemand arrived near Motiers, and he attributed its cessation to the high poplar trees in the neighbourhood of that place. Stopping at Motiers only a short time, he took a guide with a lantern to find the umbrella. Having done so he sent back the man, and went on himself towards Fleurin. As the tempest had diminished, he used the umbrella; and, as soon as the light of the lantern was sufficiently removed, he again remarked luminous appearances. These occurred at each end of the whalebone ribs, on the metal point which terminates them: the light was not so bright as the electric star, but they were brilliant points like a yellow red metal, highly polished, and would, M. A. remarks, have appeared very beautiful if he had been collected enough to admire them. M. Allemand explains these effects by supposing the atmosphere sursaturated with electricity, and that a portion of it was continually passing to the ground, through his hat, umbrella, and himself.

### Illumination by Electricity.

457. Professor Meinecke of Halle, has, in a late number of Gilbert's Annals, proposed to illuminate halls, houses, and streets, by the electric spark, and expresses his strong persuasion that one day it will afford a more perfect and less expensive light than gas-illumination, and ultimately replace it. His plan is to arrange, what are called in electricity, luminous tubes, glasses, &c., i. e. insulating substances, having a series of metallic spangles at small distances from each other, along the place to be illuminated; and then by a machine send a current of electricity through them: sometimes also partially exhausted glasses, as the luminous receiver, conductor, &c., are used. In this way professor Meinicke obtained from a two feet plate machine a constant light in his apartment, equal to that of the moon, and even surpassing it; and by enclosing his system of sparks in tubes filled with rarefied hydrogen gas, in which gas it is assumed that the electric spark is more than doubled in brilliancy, thinks it will be easy to enlarge the plan to any extent.

# INDEX.

# ELECTRO-GALVANISM.

1. Electro-Galvanism, or Voltaic Electricity, may be said to owe its origin to the discoveries of an ingenious Italian philosopher, named Galvani, who published a Latin treatise on the subject at the close of the last century.

2. In the preceding article we have examined the various phenomena resulting from the friction of dry bodies, which, by their mutual action on each other, tend to destroy their electrical equilibrium; and we now propose to furnish our readers with an outline of that branch of electricity which has led to some of the most important discoveries and splendid triumphs connected with the progress of chemical science.

3. In the year 1790 L. Galvani, professor of anatomy at Bologna, accidentally discovered that the passage of a small quantity of electricity, through the nerve of a frog that had been recently killed, had the property of exciting distinct muscular contractions. He produced the same effect with atmospherical electricity; and afterwards by the mere contact of two different metals. His discoveries were published in 1791: he proved the phenomena to be electrical, and says, 'if you lay bare the sciatic nerve of a frog, and remove the integuments, then place the nerve on a piece of zinc, and a muscle on a plate of gold, and connect these metals by any conducting substance, contractions are produced; but, if nonconductors are used to connect the metals, contractions are not excited.' The experiments of Galvani received considerable attention; they were varied and extended with the greatest perseverance and address by professor Volta, Dr. Valli, Humboldt, Fowler, Monro, Robison, and many others.

4. The effects obtained in the experiments of these naturalists may be illustrated by very simple experiments. The most important facts they establish are, first, that the passage of a small quantity of electricity through the nerve or nerves of any animal, occasions a tremulous motion or contraction of the contiguous muscles, and sometimes an extension of the limbs. This effect takes place both in living animals and such as have been recently killed, and even in the detached limbs of these last. It is produced when the transmitted electricity is too weak to affect the most delicate electrometers, and obtains in all animals for some time after death; their susceptibility being greatest at first, and gradually diminishing as the limbs stiffen. Animals with cold blood, as frogs and fishes, retain the power of action after death longer than others, sometimes for many hours, or even days.

5. Secondly, The same effects that are produced by the passage of electricity, also result from the contact of different metals with the nerves and muscles. If a communication be formed between any nerve and muscle by a single metal, contractions are but rarely produced, and when they appear are very feeble; but if two metals are employed, in contact with each other, motion is always obtained, and the effects are most considerable when the metals are most essentially different; thus zinc and gold or zinc and silver, form a very active combination.

6. Thirdly, By the same means that muscular motion is excited in these trials, some of the senses are remarkably affected, as will be evident when the experiment is made on living animals.

7. The demonstration of these facts is easily effected. For the excitation of muscular motion any small animals may be employed; the most convenient are frogs and fishes. Frogs are peculiarly susceptible. If one of these animals be employed alive, a piece of tin-foil may be pasted on its back, and the frog being then placed on a plate of zinc, spasmodic convulsions will be produced whenever a communication is made by a wire between the zinc and the tin-foil. This experiment will succeed either in the open air or under water.

8. M. Valli, an Italian physician, was one of the earliest to enter on a series of Galvanic experiments, which he began by those that relate more immediately to animal electricity. The results of these experiments he communicated in 1792 to the French Academy of Sciences, by the members of which the experiments themselves were so much approved, that the greater part of them were shortly after repeated in the chemical laboratory of Fourcroy. They were as follows:—

9. Experiment I.—Two metallic coatings, one of lead the other of silver, were placed on a frog fastened to a table, the former on the belly of the animal, the latter on the pelvis. These metallic coatings having been brought into union by the means of an exciting arc of copper, very powerful convulsive movements were produced in the animal.

10. Experiment II.—The small sheet of lead, employed as one of the coatings in the former experiment, having been removed, so as to leave the abdomen bare, and the exciting arc applied in the same way as before, the convulsive movements took place but were not so sensible as in the other case.

11. Experiment III.—In employing two coatings of the same metal, silver or gold for instance, it was found that the effects produced by the exciting arc of copper were much weaker. When these coatings were not only of similar metals, such as copper, lead, tin, zinc, &c., but the exciting arc also, no effect was produced.

12. Experiment IV.—The coating placed on the abdomen having received an horizontal direction, insomuch that the points of contact were less numerous, the effects were proportionably diminished. As soon, however, as the coating was brought into full contact with the surface of the abdomen, they became as powerful as before.

13. Experiment V.—A frog having been skinned, and cut transversely through the middle, the nerves of the thighs were laid bare, united, and placed on a piece of gold, at the same time that the thighs themselves were brought in contact with a piece of silver. On the application of the exciting arc of copper, slight movements

were produced; as they also were when both the coatings were of silver. But when a coating of tin, lead, or copper, was substituted for the one of silver, in which the nerves were enveloped, the movements became very violent. The following gradation was, however, observed in the action of the metals: the lead produced the most powerful movements; next the tin; and, lastly, the copper. In proportion as the vitality of the frog was diminished, the metals also lost the power of governing the direction of the progress of the electric fluid in the animal. The lead, tin, and zinc preserved this property the longest.

14. Experiment VI.—Plumbers' lead, placed on each side as a coating, produced no effect when employed with an exciting arc of the same description of lead; but when different qualities of this metal were selected, such, for instance, as the lead of the assayer, and plumbers' lead, an exciting arc of either of these descriptions of metal produced very singular effects. When these two kinds of lead, in changing the different metals, were no longer productive of any effect in one of these coatings, by substituting for the lead either silver, gold, bismuth, antimony, or zinc, movements of so powerful a nature were obtained, as to enable the animal to be susceptible of slight convulsions, when the above-mentioned pieces of lead, each of them of a distinct kind, were again applied.

15. Experiment VII.—A short interval of repose having been allowed to the frog, it was found to be susceptible of convulsive movements of a forcible nature, when again subjected to the same trials.

16. Experiment VIII.—The electric power being nearly exhausted in this animal, it was found that the different metals, when they produced by their contact new convulsions, did not, on this effect ceasing, leave to the animal the faculty of displaying fresh movements with the coatings of the different kinds of lead.

17. Experiment IX.—Lastly, the electric action disappeared totally in the following order, the plumbers' lead invariably forming one of the coatings: the assayers' lead first ceased to determine the action; next the tin; next the antimony; next the zinc; next the copper; next the gold; and finally, the silver. It ought here to be noticed, that the iron had lost its exciting quality before the antimony; but it was not ascertained whether it had likewise been deprived of that quality before the lead and the tin.

18. Experiment X.—The zinc, in losing the exciting property by which convulsions had been produced on the frog, which had been subjected to the experiment for the space of an hour, was not capable of determining any farther movements when the leaden exciting arc was placed on it. It was however remarked, that movements were still produced by this metal, the moment the person engaged in the experiment removed the exciting arc, and destroyed the communication. This singular experiment was so often repeated, as not to leave any doubt respecting the result.

19. Experiment XI.—The upper part of a frog, skinned and intersected transversely, having its crural nerves armed with a piece of lead, as in the preceding experiments, was placed in a glass filled with water, while the inferior part of the animal was placed in another glass. The different parts displayed very powerful movements when the communication was established, by the means of a chain formed by the persons present, two of the persons present having been selected to touch, each of them, the water in one of the glasses. One of these individuals held in his hand a bit of metal, which he brought in contact with the coating of lead.

20. Experiment XII.—When one of the company withdrew himself in such a way as to interrupt the chain, the movements were no longer perceptible.

21. Experiment XIII.—The parts of the frog having been placed in the two glasses, as in Experiment XI., the operator could not excite any movement by establishing the communication with his two fingers. He was equally unsuccessful when, with one hand armed with a piece of metal, he touched the body of the frog, while he placed a finger of the other hand on the metallic coating of the crural nerves. But when, having a finger placed on the inferior part of the frog, he presented the piece of metal to the coating of the nerves, very powerful movements were excited in the animal.

22. Experiment XIV.—When the frog was touched with a metallic exciting arc, in an insulated state, no sensible effect was produced; but, when the metal ceased to be insulated, the effect was invariably very considerable.

23. Experiment XV.—One of the fore legs of a rabbit having been detached from the body, the brachial nerves were denudated, and armed with a piece of sheet-lead. A piece of silver, which was to act as an exciting arc, was afterwards laid on an adjacent muscle; and the result was, that very violent convulsive motions were produced in the animal. In this experiment on the rabbit, as it was afterwards varied, one of the coatings being of plumbers' lead, and the other of assayers' lead, the movements were no longer excited. When they consisted, the one of lead, and the other of iron, they produced as little effect; but when the lead, as one of the coatings, was tried with another coating, either of silver, gold, copper, zinc, or antimony, convulsive movements were produced. Combined with a coating of bismuth, the coating of lead produced but very slight movements.

24. Experiment XVI.—To ascertain the state of the electricity inherent in the animal subjected to the experiment, it was plunged into a vessel containing one of Coulomb's electrometers, and successively electrified both positively and negatively. In either of these cases the animal influenced the balls of the electrometer, so as not only to evince that the electricity was in a perfect state of rest, as well before as during the experiment, but also, that the system of the body on which it was made, presented in the most marked and striking manner, the phenomenon of a Leyden phial.

25. Experiment XVII.—The left crural nerve of a living frog having been bound by a strong

ligature, the animal lost the faculty of moving, in a natural way, the part beneath the point where the ligature was tied. The nerve, however, having been armed in the same manner as in the preceding experiments, the movements were excited as soon as the communication was established between the muscle and the part above the ligature.

26. Experiment XVIII.—The ligature having been made on the left crural nerve, sufficiently near to the muscle to be in contact with it, and on the right crural nerve in such a way as to render it disengaged and visible, the left part of the animal being in a palsied state, remained perfectly motionless, whilst the convulsive movements excited by the communication were all of them confined to the right side. The above-mentioned left crural nerve having been afterwards more effectually denudated, and separated from the muscular substance by which it was surrounded, recovered its quality as a conductor, and permitted the movements which were communicated to display themselves with considerable energy. When the ligature was forced back against the muscle, the limb again lost the faculty of motion.

27. Experiment XIX.—One of the crural nerves having been armed with a piece of sheet-lead, a communication was established between this nerve and the other crural nerve in an unarmed state. The result was, that very powerful convulsive movements were produced.

28. Experiment XX.—One of the above nerves, coated with two pieces of lead, at different intervals of the muscle, was violently agitated as soon as a communication was established between the two parts by the means of an exciting arc. The same effects were observed, notwithstanding every part of the nerve was laid bare, and separated from the surrounding muscle.

29. The earliest experiments undertaken by M. Humboldt were made in the presence of M. Venturi, professor of natural philosophy at Modena, and several medical students. The brain and spinal marrow of several frogs having been laid bare, and the animals properly armed, powerful contractions were produced, by the application of the galvanic arc, in the muscles of the thorax and abdomen, together with slight contractions of those of the thigh. Violent convulsive movements of the eyes were at the same time perceived. The diaphragm, a muscle which is in all cases extremely sensible to galvanic irritation, was also powerfully contracted. As soon as the femoral and sciatic nerves had been irritated, violent contractions were produced in the thigh. The experiments on the heart and stomach were attended by but little effect. When, however, they were made on the heart of a dog, separated from the animal, and which had ceased to contract, that action was, in a certain degree, renewed; and, in the case of the stomach, a feeble motion was induced in the parts touched by the zinc. These experiments were afterwards repeated with pretty nearly the same results.

30. As the efficacy of the different substances calculated to bring about the galvanic phenomena, and the modifications they induce, had attracted the attention of naturalists much more than the effects of galvanism itself on the animal economy, Humboldt determined to direct his experiments more particularly towards the latter. The cause of galvanism ap earing to him to reside in the body of living animals, and to be merely excited to action by extraneous substances, he was of opinion that the strongest light would be thrown on this subject by observing the phenomena the animal should present. Seeing that the magnetic and electric fluids, which are neither peculiar to the living body, nor secreted in its organs, as the galvanic fluid appears to be, have, notwithstanding, a decisive influence on the human body, as well in a healthy condition as in a diseased state, ought it not, he argued, to be concluded that galvanic researches are equally interestng to the physician and to the naturalist, insomuch that the former has a right to hope that galvanism may one day be usefully employed in the cure of particular diseases? and he adds, 'In the science of galvanism, as well as in every branch of natural philosophy, facts alone are stable and certain.'

31. The following are the conclusions drawn by Humboldt from his early experiments.

32. (1.) That the effects of galvanism are almost invariably different on different parts of animals; and that multiplied and well combined experiments on this subject may furnish a tolerably correct appreciation of the respective forces of the different extensor and flexor muscles.

33. (2.) That in animals with warm blood, the diaphragm is, of all the muscles, if not the most powerfully, at least the most easily irritable, it being the only one which constantly contracts with violence in the experiments without a chain. This may lead to a knowledge of the respective degrees of irritability residing in the different muscles.

34. (3.) That the living nerves and muscles are surrounded by an active and sensible atmosphere; and that the action of the nerve extends beyond the points at which they are distributed.

35. (4.) That galvanism is capable of exciting movements in the organs which are altogether independent of the will, such as the heart and stomach.

36. (5.) That the galvanic fluid, proceeding from an animal with warm blood, may act efficaciously on the human nerves.

37. (6.) That the galvanic phenomena take place without the intervention of any external body, which proves that the cause by which they are produced resides in the living animal economy.

38. (7.) That these phenomena may be made apparent by the means of a chain established between two points of one and the same nerve, as well as in the organs brought in contact with any part of the chain.

39. (8.) and lastly. That by the discovery of galvanism, anatomists are supplied with the means of ascertaining, in small animals, the nervous distributions which are too minute for dissection. From a comparison between many of the phenomena of living bodies with those of dead matter, Humboldt conceived the idea of

instituting a series of experiments by which vitality should be, as it were, subjected to a chemical analysis.

40. M. Humboldt's attention having been directed to other objects for more than two years, he did not think of publishing his experimental observations, until the work of our countryman, Fowler, on the galvanic influence, enlightened him as to the result of his experiments, which he had hitherto apprehended to be peculiar to himself, at the same time that similar ones were made by other naturalists; such, for instance, as the experiment of Mr. G. Hunter of York, which consisted in perceiving the flash of light without any contact of metals with the eyes. Humboldt now began to collect all that had appeared on this subject, from the origin of the discovery, and to compare this information with what he had himself observed. On reading the excellent production of Pfaff on animal electricity and irritability, he found, in the very considerable number of experiments it contains, and in the important observations by which they are accompanied, results exactly similar to those with which his own experiments had supplied him, notwithstanding a very different mode of investigation had been pursued by their author. He was now obliged to renew his labors, and to suppress at least one-half of his experiments.

41. By the observations of Messrs. Jurine, Pictet, Scarpa, Tralles, and Volta, in whose presence they were made, he corrected his ideas; and their reflections conducted him to new researches. After having collected all the observations on irritation, and on the incitability of the sensible and irritable fibre, he began with the history of galvanism, as it led to the other researches. Finding it unnecessary to go into any length of detail, in penning down his observations, the results alone being of importance, he has contented himself with pointing out the principal ones, in a loose way, and in the order in which they presented themselves to him. This work is divided into ten sections, which, after the introductory matter already given in substance, form a kind of table of the subjects they discuss, and of which the following is a brief, but faithful, analysis.

42. In the first section the author expatiates, in general terms, on the relation between galvanic irritation and incitability, and on the different degrees of the former, which, he observes, act exclusively on organic parts provided with sensible fibres. The indirect effects on inanimate matter, connected with incitable bodies, have not, as yet, been experimentally demonstrated. Humboldt, with great care and attention, caused the galvanic fluid to pass through colored liquors, and through other liquors saturated with salt. These experiments he repeated with great assiduity, but could never observe the smallest alteration in the color, temperature, evaporability, or crystallisation of the fluids in question, on the chemical combination of which he could not perceive any change to have been effected. It did not produce any sensible effect either on the electrometer, or on the intermediate rings of the galvanic chain, so as to indicate its strict analogy with the electric fluid.

43. In his investigation of the effects of a metallic stimulus on the irritable and sensible fibre, Humboldt was very solicitous to ascertain the degree of irritability and incitability, which has as powerful an influence on the success or failure of the experiments, as the degree of force of the stimulus itself. In experimenting, he therefore made choice of the most incitable animals, and found that the frogs best calculated for his purpose were young and vigorous females, taken immediately after their winter slumber, and fed, together with other frogs, for some days in a warm room. By the help of art he contrived to carry the incitability to a higher degree than is remarked in the natural state; and this discovery may be considered as one of the most important that he made. By bathing the nerves of animals with a solution of alkaline salts, or with the oxygenated muriatic acid, he not only obtained results which had not previously been known; but also noticed phenomena, the possibility of which had been denied.

44. A short time after the appearance of Humboldt's great work, M. Pfaff published an interesting memoir on the subject. 'It cannot be questioned,' says this writer, 'but that vital chemistry, which appears to be the favorite object of the meditations of the physiologists of the present day, has been elucidated, as well as greatly extended in its limits, by Humboldt's experiments on the excitability of the muscles and nerves. The indefatigable zeal employed by that writer, together with the sagacity and spirit of observation of which he has given so many conspicuous proofs, in a multitude of researches on physiology, must necessarily have led him to very interesting results. The inferences, however, which he draws from his experiments, as well as the explanation he gives of the phenomena he has observed, are not invariably fixed on a solid basis.'

45. The very remarkable effects produced by chemical substances on the sensible and irritable fibre, are, according to M. Pfaff, susceptible of an explanation different from the one adopted by M. Humboldt. It is for this reason that the former proposed another, which he thought more just, and, at the same time, more coincident with the different phenomena of galvanism. The following are his reasonings on this head, together with the experiments on which they are founded.

46. 'A very important circumstance,' he observes, 'to which Humboldt did not pay attention, in his experiments relative to the influence of chemical substances, as exciters of irritability is the effect of them as members of the galvanic chain. Among these substances may be enumerated the different alkaline substances, acids in general, the oxygenated muriatic acid in particular, and liver of sulphur. I have examined them, in the above point of view, in a series of experiments, and have found several of them to be as efficacious links of the chain, and as powerful exciters of galvanism, as metallic substances themselves.

47. 'The table published by M. Humboldt, of the intermediate links of the chain of his boasted exciters and conductors of animal ele

tricity, should be entirely altered, if it be intended to represent the scale of the conducting and exciting forces of these substances, in whatever relates to galvanism. Liver of sulphur, the alkaline solutions, lime-water, and the oxygenated muriatic acid, ought to be ranked before all other substances, metals and charcoal excepted, and immediately after them. The blood also should be considered as possessing a great degree of energy. I have convinced myself, by repeated experiments, made attentively, and with the most scrupulous exactitude, that alkaline solutions, lime-water, the oxygenated muriatic acid, and, more particularly, liver of sulphur, produce, when brought into reciprocal action, effects equally powerful with those of two heterogeneous metals; and that, in all the cases in which the recurrence of the contractions is ascribed to an increase of irritability, produced by a chemical action, it would be much better to ascribe this effect to the irritating property of these substances, as they constitute a part of the galvanic chain.

48. 'They form, in a manner, a series of metallic exciting arcs; and ought to be ranked among those which have the greatest affinity with metallic substances, that is, with zinc and lead. It is on this account that their effects are so obvious, when they are combined with gold, silver, and metallic minerals. They are also very efficacious in the reproduction of the contractions, when, instead of being applied in an immediate way to the nerves, they are simply made to correspond with them by the means of conductors. The blood and the bile ought also to be comprehended in the same class, although their effect may not be equally powerful.

49. 'It is well known that it suffices, for the production of convulsive movements in a very irritable frog, to employ a homogeneous metal, for instance a silver discharger, by which a communication is formed between the muscles and the nerves. These convulsive movements are principally produced by the metals denominated noble; but, more especially, by metallic minerals, such as pyrites and galena, or sulphuric ore of lead. When I had formed a communication between the nerve and the prepared thigh of a frog, by the means of a piece of pyrites, the convulsions were produced, and were more particularly manifested when that substance touched the blood-vessels belonging to the nerves. When a chain was established in the thigh, and the mineral substance and nerve had ceased to produce any effect, the convulsions were reproduced, although feebly, by interposing in the chain a piece of moistened sponge, which formed, in a manner, a coating to the nerves. These effects were not usually, however, of any long duration. By moistening, afterwards, the nerve with a drop of blood taken from the frog subjected to the experiments, or, what amounts to the same thing, from any other, and afterwards touching the blood in question with a metallic exciter of silver or copper, placed on the thigh, very powerful convulsions were instantly produced.

50. 'Here the susceptibility of irritation was evidently augmented by the moistening of the nerve with the blood. It was even so to such a degree, that a galvanic irritation of the feeblest kind became very powerfully augmented. This augmentation of the contractions was not, however, to be ascribed to an immediate influence of the blood on the nerve, or on the irritability seeing that the same phenomena were manifested, precisely in the same way, when the blood, instead of being immediately applied to the nerve, was simply laid on a bit of sponge, or on any other conducting body, placed over it. The success of the above experiments depended entirely on the immediate contact of the blood; since, whenever the nerve, or the sponge, was touched at the parts distant from it, the effect did not ensue. To the presence of the blood ought more particularly to be ascribed the properties of animal substances, considered as members of the galvanic chain.

51. 'In this latter point of view, the heart of the frog, still replete with blood, displayed very singular effects, at a time when the irritability was extinguished to such a degree, that certain heterogeneous metals, such as gold and silver, or silver and copper, no longer produced any effect when brought in contact. I was enabled to reproduce very forcible contractions, by placing the heart of a frog on its nerve, and by forming a communication between it and the thigh of the animal, by the means of a metallic exciting arc either of gold or silver. In this manner I established a galvanic chain, in the composition of which one metallic exciter only was to be found. In another instance, it was very remarkable, that the moment the heart was touched, either by silver or by pyrites, it remained tranquil, notwithstanding the thigh of the animal was in a convulsed state, the regularity of the system of the pulsations not being in any degree interrupted. Other parts of the frog, for instance, portions of its liver, its bowels, &c., which contain a less proportion of blood, did not possess an equal efficacy; but the heart itself was surpassed by the blood presented in substance, and more particularly in a concrete state. It was surprising to see the mode in which I could, by the means of a drop of blood, bestow on the nerve its vital energy; and also to observe that this drop of blood, without undergoing any sensible diminution or change, still continued to render the same service.

52. 'Whatever may be the effect, however, which the blood produces, it is still surpassed by the alkalies, by the oxygenated muriatic acid, and, more particularly, by the liver of sulphur, when metallic exciters of the first class, that is, the minerals and noble metals, together with the other metallic substances, and the regulus of antimony, cease to produce any effect, in conjunction with the blood with which the nerve has been moistened. After having wiped it dry, and substituted for the blood a single drop of the deliquescent oil of tartar, very powerful convulsive movements may be produced, by a recurrence to the above metallic exciting substances. This galvanic chain, consisting of muscles, silver, pyrites, or regulus of antimony, and of an alkali and a nerve, is as efficacious as a chain formed by muscles, silver, iron, or tin, conjointly with a nerve. The deliquescent oil of tartar

may be considered as an active coating of the nerve. These phenomena present themselves agreeably to the same identical laws by which the metallic coatings of the nerves are regulated. In the above process, the deliquescent oil of tartar possesses nearly the same activity, whether the nerve, without being moistened in an immediate way, is made to communicate with the muscles by the means of any conducting body whatever, or is immediately touched by the metallic exciter applied to the thigh of the animal, the exciter in question being a bent silver probe.

53. Professor Pfaff goes on to say that 'the following experiments merit a particular notice. I laid a portion of muscular flesh on the nerve of a frog, on which two heterogeneous metals, silver and copper, had ceased to produce any effect, and having touched the nerve with a silver probe, which was applied to the thigh, was not enabled to produce any contractions. I now poured a drop of the deliquescent oil of tartar on the muscular flesh, and, as soon as the silver probe was brought in contact with this alkaline substance, very strong convulsive movements were displayed. I laid another portion of muscular flesh on the preceding one, and brought the exciter towards it, but without being enabled to produce the contractions. Scarcely, however, had this latter portion of muscle been moistened and touched, as in the former instance, than they were renewed. In this way I was enabled to form several layers of a different nature; and the effect above pointed out took place as often as the silver, or, what was still better, the pyrites and the regulus of antimony, came in immediate contact with the alkali. The nerve having been moistened with the deliquescent oil of tartar, a very feeble galvanic irritation, produced either by gold and silver, or by silver and copper, became highly exalted, even when the convulsions had not been previously excited. It remains, however, to be ascertained, whether, in this case, the deliquescent oil of tartar did not act as the most efficacious coating of the nerve. It is in this way that silver and copper produce fresh contractions, when, after the nerve has been coated with zinc, and the thigh of the animal laid on silver, a communication is formed between them by the means of copper. In such a case, indeed, the effect is not owing to the joint operation of the copper and silver, but, on the other hand, to that of the silver and zinc, by which the humid animal parts are immediately coated. Would not an effect exactly similar be produced, if the nerve were to be moistened with the deliquescent oil of tartar? Does not this alkali, in surrounding the nerve, become a more efficacious coating than the zinc; and, on the application of feeble exciters, such as copper and silver, does not the zinc itself act more powerfully by the means of an alkali, with which it is simply connected by the copper, as an intermediate conductor?

54. 'These doubts are very far from being removed by M. Humboldt's experiments. Supposing the deliquescent oil of tartar to act by producing an augmentation of irritability, this effect ought also to be produced when the nerve has been carefully dried, before the application of a weaker galvanic irritation is made. This, however, is what I have not found in any of my experiments. M. Humboldt constantly applied his weakest exciters, whilst the nerves were still moistened with the deliquescent oil of tartar, or with any other chemical substance calculated to augment the susceptibility of irritation. On this head, let the different parts of his work in which he treats of the increase of this susceptibility by the alkalies, be compared. He sets out by saying: 'I showed the galvanic flashes to several persons who could not perceive them in the experiments made by Mr. G. Hunter, by rubbing their gums, on the upper jaw, with an alkaline solution. Two pieces of gold, applied to wounds on the back, were found to possess great efficacy, when the wounds had been touched with the deliquescent oil of tartar.' A little farther he observes: 'When the principal trunks of the nerves of an organ are carefully prepared, and enveloped in moist bits of bladder, in such a way as that the irritating humidity simply moistens the muscular flesh, and the few fine nervous filaments it contains, an increase of irritability is rarely to be observed, at the same time that it is constantly produced, when the above principal trunks are moistened beneath the muscles.' Again, he says in the following page: 'The vital principle will be restored in the thighs of frogs exhausted by galvanic experiments, by the means of the oxygenated muriatic acid, in such a way as that the irritation of metals will again produce its effect. It is remarkable, that the contractions become more powerful, when a great portion of the nerve is moistened, and touched directly by the silver.' Such are the extracts I have chosen to cite from Humboldt's work. Now, let it be observed, that, in all the above cases, and more particularly in the experiments relative to the influence of chemical substances on the irritability of the animal fibre, the nerves were constantly moistened by these substances. They must consequently, whenever the metals were applied, operate likewise as links, or members, of the galvanic chain. The consequences must therefore be uncertain at the least.

55. 'I could not observe any remarkable difference in the alkalies, considered as links of the galvanic chain. The deliquescent oil of tartar appeared, however, to be somewhat more efficacious than the other substances of this nature. The effects of lime-water were not so powerful: it appeared, as it were, to preserve a medium between the alkalies and the substances to which an inferior rank is assigned. The oxygenated muriatic acid appeared to be pretty nearly as active as the deliquescent oil of tartar. In a few cases only the latter fluid produced spasmodic contractions of a longer duration. I observed likewise, in several instances in which I employed the oxygenated muriatic acid, a phenomenon which the metallic coatings of the nerves had often displayed, namely, that the contractions were manifested at no other time than when the contact of the nerve, moistened with a drop of the oxygenated muriatic acid, ceased. Here, likewise, the effects seemed to depend entirely on the immediate presence and application of

the oxygenated muriatic acid. As soon as a drop of this liquid is poured on a portion of muscular flesh, laid on the nerve, the movements are invariably reproduced.'

56. Having entered into this detail of the objections of M. Pfaff to the theory of Humboldt, we may now proceed to the analysis of a very curious memoir, read by M. Lehot at the French National Institute. Its object is to demonstrate particularly, not only the circulation of a very subtile fluid in the galvanic chain, but likewise that, in the application of the different chains to the animal arcs, there are unequivocal signs of the direction of the motion of that fluid, insomuch that it is possible to determine a priori, in a considerable number of different chains, the direction of the current. Being acquainted with this direction, as well as with the nature of the different parts of the chain, the author of the memoir in question observes, that it is reciprocally possible, in certain cases at least, to determine their respective position; and also, by the interposition of new substances in the chain, or by a change in the disposition of the parts of which it is composed, to give a particular direction to the galvanic fluid, and even to bring it into a state of repose.

57. The comprehension of these phenomena is connected with a fact which seemed to have escaped the notice of the different physiologists, namely, that the galvanic fluid is accumulated in the passage from the organs to the coatings. By a due attention to this fact, the nature of the metallic substances may likewise be distinguished at the distance of several yards. The galvanic influence will be sufficient to determine this. The following are the principal results of the interesting experiments made by M. Lehot.

58. Experiment I.—If the thigh of a frog recently prepared be held in one of the hands, and the nerve be brought in contact with a piece of zinc, the extremity of which is immersed in mercury, the moment the fingers of the other hand are dipped in that fluid powerful contractions will be manifested in the thigh of the animal. The same result will be obtained as often as one of the following substances, namely zinc, lead, tin, mercury, bismuth, copper, silver, or plumbago, is employed as a coating to the fingers; and one of those by which it is preceded, in the foregoing series, as a coating to the nerve. With respect to the precaution of moistening the fingers, it is absolutely indispensable; for which reason, whenever they are described as terminating one of the extremities of the arc, they are to be constantly supposed to be in a humid state.

59. Experiment II.—If, on the other hand, the nerve be brought in contact with the mercury, and if that metal be touched with a piece of zinc, held in the moistened hand, either the contractions will not be produced, or they will be extremely feeble, provided there still be a certain share of susceptibility in the part. By separating, however, the nerve from the mercury, or, in general, by breaking the chain at any given point whatever, the contractile movements will take place. The same results will be obtained, as often as one of the metals belonging to the series pointed out in the preceding experiment, is employed as a coating to the fingers; and one of those by which it is followed in that series, as a coating to the nerve. Thus, if the nerve be coated with lead, and the fingers with zinc, there will not be any contraction when these two metals are brought in contact; but, if the chain be destroyed at any given point, the contractions will be manifested. If, on the other hand, the nerve being still coated with lead, the fingers be coated with silver, when the chain is formed, the galvanic contractions will take place.

60. Experiment III.—If a flat surface of zinc be laid on the tongue, and touched with a piece of silver, held between the moistened fingers, a particular savor will instantly be perceived. Much has been said on the subject of this phenomenon, but it has been nowhere noticed, that it likewise takes place whenever the tongue is coated with any one of the metallic substances pointed out in the first experiment, and the fingers with one of those by which it is followed in the series. If, however, after the chain has been formed, it be interrupted, the savor will be no longer manifest.

61. Experiment IV.—If a piece of silver be laid on the tongue, and a portion of zinc be held between the moistened fingers, as soon as the latter is brought in contact with the silver, there will not be any distinguishable sensation, or, at the least, it will be very slight. As often, however, as the chain is interrupted in any given point whatever, the savor will be perceptible. It will not in this case be so strong as in the preceding experiment, and will be more slowly communicated.

62. The same result will be obtained, as often as one of the metals pointed out in the first experiment is employed as a coating to the tongue, and one of those by which it is preceded in the list, as a coating to the fingers. Thus, by coating the tongue with lead, and the fingers with zinc, and by bringing the two metals in contact, the savor will not ensue; but, by interrupting the chain at any given point, it will be very perceptible. On the contrary, if, the tongue being still coated with the lead, the fingers be coated with silver, instead of zinc, and the chain established, the sensation will be instantly perceived.

63. Experiment V.—If the thigh of a frog be laid on a plate of silver, and the nerve on a surface of zinc or lead, the moment the coatings are brought in contact, powerful contractions will be produced. The same thing will happen whenever the coating of the nerve is made to consist of a metal selected from among those which are pointed out in the first experiment; and that of the muscle, of another metal following it in the series.

64. Experiment VI.—If the muscle be armed with zinc, and the nerve with silver, the contractions will not ensue until the moment the chain is interrupted. When portions of copper, iron, bismuth, and lead are substituted for the silver, the same results are obtained.

65. In the first, third, and fifth, of the preceding experiments, it must have been observed, that

the phenomena were manifested the moment the galvanic circle was formed. The fluid contained in the part of the chain was put in motion, and penetrated instantly either to the tongue or to the nerve. By reversing the chain, a contrary direction must have been given to the current, seeing that the phenomena which were manifested in the second, fourth, and sixth experiments, that is, those in which the galvanic influence was not perceptible until the instant when the chain was interrupted, were to be ascribed to a portion of the fluid, accumulated either in the tongue or in the nerves, at the points of contact of these organs with their coatings. Now, to the end that the fluid should have been thus accumulated, it was necessary that it should have penetrated the above organs in the direction of the muscle towards the nerves, or of the fingers towards the tongue. It is thus demonstrated, that the accumulation of the fluid is a sure characteristic of the direction of the current, by the help of which it may in all cases be determined.

66. In conformity to the experiments which have been detailed above, and to the galvanic facts previously known and established, it would appear that the following principles may be laid down.

67. (1.) That all exciting substances contain the galvanic fluid; but that its quantity is very considerable in humid substances, and in the organs of animals, which have a very small capacity for that fluid, when compared with metallic substances.

68. (2.) That, when two exciting substances are brought together, a new distribution of the galvanic fluid takes place; the substance which has the least capacity losing a portion of the fluid, on which the other substance seizes. Metallic and carbonated substances, disposed in the following order,—zinc, lead, tin, mercury, bismuth, copper, silver, and plumbago, act in such a manner as that any one of them, when brought in contact with one of those by which it is followed, seizes on a portion of the fluid the latter contains.

69. (3.) When the galvanic fluid penetrates the tongue, in directing itself from its extremity towards its root, it causes in the latter part a particular savor, which is more or less strong, according to the greater or less quantity of the fluid, and to the susceptibility of the organ. But when its direction is such, that it tends to flow out of the animal arc by the tongue, it occasions a much weaker savor, which differs from the former in proportion as the quantity of the fluid put in motion is less. As the fluid, however, finds some difficulty in quitting the tongue, it partly accumulates in that organ; and when the cause that has given rise to this accumulation ceases, then the fluid, in returning towards the root of the tongue, occasions there the galvanic savor in question.

70. (4.) When the galvanic fluid, distributed by the nerves, penetrates into the muscular substance of the organs of living animals, recently separated from the animals themselves, contractions are produced in the parts it permeates. The susceptibility being exalted, if the fluid inherent in the organ should, from any cause whatever, be unequally distributed, and accumulated at the particular points, muscular movements will ensue. But if the susceptibility is weakened, the contractions can no longer take place, unless by the aid of a fluid extraneous to the organ.

71. At the earliest stage of the diminution of the susceptibility of the organs, the contractions are displayed, whatever may be the direction of the fluid by which they are permeated. But when the susceptibility is weakened still more, the direction of the current ceases to be indifferent. When the fluid is directed in such a way as to pass from the nervous ramifications to the nerves themselves, the contractile movements are much weaker than when it receives a contrary direction; and in the former case a portion of the fluid becomes accumulated at the point where it has a tendency to flow out from the nerve. This accumulation, and this difference in the effect of the current, by which the organ is penetrated in one direction or in another, are greater in proportion as the susceptibility is less, and as the quantity of the fluid put in motion is smaller. Thus, when the susceptibility is greatly enfeebled, notwithstanding the contractions may ensue, when the fluid penetrates into the organs, in the direction leading from the nerve to the muscle, they cease altogether when it permeates them in a contrary direction, it being then almost completely accumulated in the organ. The cause which has given rise to this accumulation having ceased, the fluid returns into its accustomed channel, and, having penetrated the organs in the most favorable direction, occasions in them the muscular movements.

72. (5.) If a communication be established between two points of an animal organ, with the help of a chain composed of different substances, disposed in such a way as that it may not be symmetrical, relatively to the nature of the parts of which it is composed, the fluid, being unequally solicited on the one hand and on the other, puts itself in motion, and forms a current directed towards the preponderating force.

73. (6.) If all the parts of the chain, by which a communication is established between two points of a system of organs either nervous or muscular, be reversed, a current will be produced having a contrary direction to the former.

74. (7.) When the chain is symmetrical, relatively to the nature of the parts of which it is composed, the fluid, being equally solicited on all sides, will forbear to display any movement.

75. (8.) and lastly. When a chain, which is calculated by its nature to give motion to the galvanic fluid, is destroyed, that is, when an insulating body is interposed, the fluid, which had been accumulated in the organ by the formation of the chain, returns to its original situation, and a current is formed into a contrary direction to the first.

76. These principles, which form the basis of M. Lehot's theory of galvanism, are likewise confirmed by the following experiments:—

77. If the thigh of a frog be held in one of the hands, and the nerve coated with zinc, at the same time that the person who makes the experiment has his tongue armed with silver, the

thigh of the frog will contract as soon as the two metals are brought in contact; but the experimenter will not be sensible of any savor, or of a very slight one at the most. By interrupting, however, the chain, he will perceive a very distinct savor, and the thigh of the frog will cease to contract. If, on the other hand, he coats his tongue with zinc, and the nerve with silver, the peculiar taste will be manifested at the moment of the contact; and the thigh, provided its incitability has been weakened, will preserve a state of perfect immobility.

78. By the interruption of the chain, the muscular movements will be again apparent, without any manifestation of the galvanic taste. It will appear that this ought necessarily to happen when it is considered that, as soon as the chain is formed, the current of the fluid takes a direction from the silver to the zinc, and, having penetrated in a direct and immediate way into the nerve, produces contractions in the muscle, at the same time that it crosses the body of the person by whom the experiment is made, and accumulates on his tongue, without his being sensible of any particular savor. When, however, the chain is interrupted, the accumulated fluid returns to the parts it had quitted, and the savor on the tongue becomes manifest. If the tongue be coated with zinc, and the nerve with silver, the current being impelled in a contrary direction, the phenomena which take place are diametrically opposite.

79. If two persons, holding each other by the hand, arm the tongue, one of them with zinc, and the other with silver, as soon as they bring the two metallic substances in contact, the one who has the tongue coated with zinc is sensible of the savor; but this does not happen to the other. If they afterwards separate the zinc from the silver, the one who felt the savor at the time when the chain was formed, will cease to be sensible of it on its being thus interrupted; at the same time that it will be rendered manifest on the tongue of the other.

80. Finally, the animal arc may be terminated by two nerves. Thus, by placing the two thighs of a frog on a plate of glass, and establishing a communication between their muscles, by the help of a flat piece of metal, coating, at the same time, the nerve of one of them with zinc, and the other with silver; the thigh which is armed with zinc will contract the moment a communication is established between the two coatings, by the means of a rod of zinc or silver; the incitability of the other thigh having been weakened, the limb will remain motionless. By interrupting the chain, however, the muscular movements will be displayed in the latter, and the former will resume a state of repose.

81. The same disposition being made as in the second experiment, and the chain established, if a given point of the muscle be brought in contact with the mercury, without deranging the contact of the nerve; or if a communication be established between the muscle and the mercury, or between the muscle and the zinc, by the means of a metallic substance, the muscular movements will be instantly manifested. These phenomena are occasioned by the fluid accumulated at the point of contact between the nerve and its coating, which fluid returns into the muscle, and there gives rise to the contractions. This is shewn in the following manner:—If, while the communicating metallic substance still touches the muscle and the mercury, or the muscle and the zinc, the latter be detached from the mercury, the contractions will not ensue, as would have happened if the fluid accumulated by the original chain, at the point of contact of the nerve and its coating, had remained there.

82. If the thigh of a frog, prepared in the customary manner, be held in one of the hands, and the nerves, as well as a few points of the muscle, be brought in contact with the mercury, the moment that fluid is touched by a bar of zinc, held in the other hand, previously moistened, violent contractions will be produced in the limb of the animal. This experiment consequently presents phenomena entirely different from those which were the result of the second experiment. The fluid, instead of having been accumulated in the nerve, appears to have flowed out by the muscle, and to have there occasioned the contractions. Such a degree of incitability may be induced, that the contractions may be altogether subdued by the double contact of the nerve and the muscle, as well in forming as in interrupting the chain.

83. If the same disposition having been made as in the sixth experiment, not only the nerve, but likewise the muscle, be made to touch the piece of silver, leaving it, however, in constant contact with the zinc, violent contractions will be manifested as soon as a communication is established between the zinc and the silver, by the means of a conducting substance. By substituting for the silver either copper, plumbago, or lead, the same phenomenon will be obtained.

84. The current which is formed in a chain composed of three metallic substances, is constantly directed towards the extreme metal stationed in front of the metal at the other extremity of the chain. The direction of the current cannot therefore depend, in any degree, on the metal by which the middle space is occupied.

85. In the chain composed of metallic and humid substances, where there are only two or three heterogeneous metals in immediate contact, the current is directed in the same way as it would be if these metals were to be regarded as independent of the rest of the chain.

86. Having placed a thin plate of zinc at the bottom of a vessel filled with water, and brought the tongue in contact with the extremity of a bar of tin, the other extremity of which is made to touch the plate of zinc; if another bar of the same metal, of the same dimensions with the preceding one, be held in one of the hands, and its extremity plunged in the water, there will not be any perceptible savor. In reality, the current is, in this instance, directed in such a way as to pass through the fingers, crossing the body of the person by whom the experiment is made, to accumulate itself on the tongue. But as soon as the second bar of tin is plunged more deeply in the water, so as to touch the zinc, the savor becomes perceptible. This phenomenon, which had not hitherto been noticed, is, according

to M. Lehot, a natural result of the principles he has laid down. By bringing, he observes, the second bar of tin in contact with the zinc, a symmetrical chain is formed, of such a nature, that the fluid it contains must necessarily be in equilibrio. Consequently, the quantity of the fluid which had been accumulated in the preceding disposition, must, unavoidably, have been dispersed, and have occasioned the sensation or flavor which was noticed. On detaching the bar of tin from the plate of zinc, without taking it out of the water, the sensation ceases to be perceptible, on this account, that a current is formed which is directed in such a way as to penetrate the fingers. If the bar of tin be withdrawn from the water, the flavor will be perceptible, in consequence of the dispersion of the accumulated fluid.

87. Thus, to render a chain symmetrical, or to destroy it by the interposition of an insulating substance, will have the same effect relatively to the motion of the galvanic fluid. By the explanation which has just been given, it seems evident that if, after rendering stationary the bar which touches the tongue, and the one which is held in the hand moveable, the operation be performed inversely, the savor will be felt in contrary circumstances; seeing that the current will, in every such case, take an opposite direction.

88. When the extremity of the moveable bar is plunged in water, the one which is held in the moistened hand being fixed, and in contact with the plate of zinc at the bottom of the vessel, the sensation is perceptible on the tongue. But if the former be plunged still deeper, so as to be brought to touch the zinc, the savor will be no longer manifested. On detaching it from the plate of zinc, without, however, withdrawing it from the water, the sensation is again produced; but ceases as soon as the bar is taken out of the water.

89. If the extremity of each of the two bars of tin be laid on a particular point of the tongue, the savor will be felt at the extremity of the moveable bar, the moment its other extremity is plunged in the water, that of the fixed bar being in contact with the plate of zinc. Secondly, by plunging the moveable bar still more deeply in the water, and bringing it in contact with the plate of zinc, the savor will be felt at the point of the tongue where it is touched by the other bar. Thirdly, the instant either of the bars is separated from the plate of zinc, without being, however, taken out of the water, the galvanic savor will be distinguishable at its point. Lastly, the one which was stationary in the first instance, still continuing so, if the moveable one be taken out of the water, the savor will be felt at the extremity of the former.

90. From the principles which have just been laid down, it is not difficult to conclude that, if a metal, taken from the given series, be employed as a bar, and one of those by which it is followed in that series as a communicator plunged in water, the phenomena which take place in the preceding experiments will be entirely changed. Consequently, the cases in which, in the first and second of the above experiments, the sensation was manifested, are precisely those in which there should not be any sensation, under the circumstances above stated, and vice versa. It also follows that, in the third experiment, the cases in which the savor was perceptible at the extremity of the moveable bar, are those in which, under these circumstances, it should be felt at the extremity of the fixed bar, and vice versa; the current then invariably taking a contrary direction.

91. Having placed the nerves of the thigh of a frog on a plate of tin, terminated by a small cavity filled with water, and the muscles on another plate of tin exactly similar, if one of the extremities of an arc of zinc be brought in contact with the bottom of the cavity formed in the coating of the nerve, and if the other extremity of the arc be immersed in the water contained in the cavity of the coating of the muscle, the susceptibility of the organs will be found to be such, that the contractions will not ensue. By plunging the communicator, however, still more deeply in the water, in such a way as that it may touch the bottom of the latter of the above cavities, the contractions will be instantly manifested in the animal arc. Having afterwards detached the arc of zinc from the bottom of the cavity of the coating of the nerve, without, however, withdrawing it from the water, the organ becomes motionless; but, as soon as the arc ceases to be immersed in the water, it being, at the same time, still in contact at its other extremity, the contractions are again produced. This experiment was frequently repeated by our author, and was constantly attended by the same result. In the latter instance, however, the contractions were invariably weaker than in the former.

92. If the arc of zinc be brought in contact with the coating of the muscle, at the same time that its other extremity is plunged in the cavity of the coating of the nerve, the thigh of the frog will be forcibly contracted. By immersing it still deeper, so as that it may reach the bottom of the cavity, the contractions will cease. In detaching it, the muscular movements are usually perceptible; but there are occasions in which the organs remain motionless.

93. The same results will be obtained as often as a more oxydizable metal is employed, to establish a communication between two homogeneous coatings, formed of a weaker metal. If coatings of a metallic substance, possessing a greater capacity, be employed in conjunction with a communicator or arc, which has a less capacity, the effects which will be produced will be diametrically opposite.

94. The experiments which have been thus detailed, lead to a very singular result, namely, that one metal may be distinguished from another without being either directly seen or felt. In reality, by composing a chain in such a way as that it may be terminated by one of the metals described above, a current being formed which takes a particular direction, totally different from the one which it takes when the chain is terminated by another metal, it is easy to recognise any one given metallic substance. In this way M. Lehot was enabled to distinguish a portion of zinc from a piece of silver, at the extremity of metallic threads several yards in length

95 About this period professor Volta took up the subject, and philosophy has to rejoice that his mode of theorizing, although not strictly true, has contributed principally to its rapid advancement. He set out with the idea, contrary to Galvani, that the electricity in question did not belong to the animal, but to the different metals employed. Galvani, therefore, was unlikely to produce any greater effect than what two pieces of metal could effect, because he believed the electricity to be in the animal. Volta was led to the discovery of the battery by combining a number of pieces of metal together, because he was persuaded that the electricity was in the metals and fluids employed.

96. He repeated the experiments of Galvani, and found that when two pieces of metals of different kinds were placed in different parts of an animal at the same time that the metals were brought in contact, or were connected by a metallic arc, as often as the contact was made, convulsions were observed. He found that the greatest effect was produced when the metals were zinc and silver. When several pairs of metals were employed, having pieces of moist cloth between them, the effect appeared to increase as the number of pairs.

97. This important discovery of accumulating the effects of this species of electricity was made by Volta, in 1800, and thence has been denominated the Voltaic pile. The apparatus, as first made by Volta, consisted of a certain number of pairs of zinc and silver plates, separated from each other by pieces of wet cloth. Hence the arrangement was as follows: zinc, silver, wet cloth; zinc, silver, wet cloth, and so on. The silver plates were chiefly silver coins, the plates of zinc and the pieces of cloth being of the same size. He found this pile much more powerful when the pieces of cloth were moistened with a solution of common salt instead of pure water. A pile, consisting of forty pairs of plates, he found to possess the power of giving a very sharp shock, similar to that of a small electric jar; and that this effect took place as often as a communication was made between each end of the pile, and as long as the pieces of cloth remained moist.

98. An account of this discovery was communicated to the Royal Society, and published in the Philosophical Transactions. We do not find that this celebrated philosopher made any considerable discoveries after the invention of the pile.

99. The galvanic pile invented by M. Zamboni, and which he has called a binary pile, is composed only of two elements, namely, a metal and a fluid. The metallic elements of the pile are twenty-nine small squares of tin-foil, about half an inch long on each side, and terminated by a very fine tail, from two to three inches in length; and the fluid element is distilled water, placed in thirty watch glasses, arranged circularly on a table. The water in every two adjoining glasses is connected with one of the elements of tin, by placing the square portion of the tin in one glass, and the tail in the adjoining one in such a manner that the square portion is wholly immersed, while the tail merely touches the fluid. When the metallic elements are all arranged in a similar manner, and when the first and last glasses communicate only by means of all the intermediate ones, it will be found by making a communication between the first glass and the ground, and between the last and a good condenser, that the pile has two poles, one vitreous and the other resinous, the former corresponding to the small squares, and the latter to the long tails.

100. If the pile is constructed with elongated rectangular pieces of tin, no electricity is developed when the two extremities of the rectangles are equally immersed in the distilled water of the watch glasses; but, whenever they are immersed unequally, the electricity exhibits itself at the poles, as in the construction already described; the vitreous pole always corresponding to the larger surface immersed, and the resinous one to the smaller surface, so that the same pole may be rendered alternately vitreous and resinous, by immersing more or less of the nearest ends of the rectangles of tin.

101. When elements of zinc or copper are substituted in place of the tin, the same effects are produced; but no indications of electricity are obtained from oxide of manganese.

102. A pile constructed in the preceding manner does not charge the condenser instantaneously. The electricity does not appear till about the end of half a minute, and often longer, and it then gradually increases. This effect might be ascribed to oxidation, as the pile would then have three elements; but at the end of several days the development of electricity was as powerful as at the moment when the apparatus was arranged, although not the slightest trace of oxidation could be perceived. When zinc was substituted for tin, the electricity diminished as the oxidation increased; it then disappeared and afterwards reappeared, with an opposite character. Hence it would appear that the development of electricity in the binary pile is not owing to the oxidation of the metal.

103. A pile constructed with ten discs of tinned paper, without any other substance, produced, in about half a minute, a deviation of a third of an inch in Bennet's electrometer, furnished with a condenser. The tinned face possessed vitreous, and the paper face resinous, electricity. This effect invariably increased with the number of the discs.

104. Another pile of discs of tinned paper, having the paper face covered with a film of honey, in order to keep up a constant humidity, likewise gave signs of electricity, but it required from forty to fifty discs to produce the same degree of electricity as the preceding pile of ten discs of tinned paper; and the electricity was besides of an opposite character, the honey being vitreously, and the tin resinously, electrified. On the following day the electricity had rapidly diminished, and at last it completely disappeared, the paper having been penetrated throughout with the honey, and the tin being equally in contact by its two surfaces with the latter substance.

105. A pile of discs of tinned paper, in which all the discs had been glued together, gave no electrical indications, because the metal was equally in contact with the paper at each of its faces.

106. When a binary pile, like any of the preceding, has become inactive, its energy may be restored, by simply raising the discs, which, by the action of the air, will diminish the influence of humidity upon one of the faces of each disc. The binary piles, indeed, do not produce any effect, unless the touching surfaces of the metallic and the fluid element are unequal.

107. The energy of the binary piles is much influenced by the conducting power of the fluid which forms the humid element. A few drops of a solution of sal ammoniac added to the distilled water, augments a little the electricity of the pile; but if we continue to add more, a diminution of action takes place, and at last the energy of the pile is destroyed. Hence it follows, that the humid element must be an imperfect conductor.

108. Mr. Singer, in his first experiments, cut a number of thin slips of sheet copper, and bent them into the form of the letter U, so as to form a series of simple springs. He then introduced both legs of one of these springs into each cell of a Voltaic battery, so that it pressed forcibly against the copper surface on one side of the cell, and the zinc surface on the other. Having, in this manner, made a regular metallic communication between every pair of plates in a battery containing fifty of three inches square, Mr. Singer filled the cells with a diluted acid, and found that, notwithstanding the total absence of insulation, water was decomposed with great rapidity, a vivid spark produced by charcoal points, and gunpowder inflamed; and, on applying the condenser, a charge was communicated which occasioned the gold leaves of the electrometer to strike the sides of the glass.

109. This phenomenon appears the more extraordinary at first view, because it is well known that, if the plates are all connected together by a thin wire, the effect is almost totally destroyed; but in such case, the opposite copper and zinc surfaces of each pair of plates are made to communicate with each other, and consequently their electricities circulate individually, instead of being propelled forward from one cell to the other. But, in the arrangement above described, the metallic springs are in contact with the zinc surface of one pair of plates, and the copper surface of another; there is consequently no communication between the opposite surfaces of any individual pair, but what arises from the association of the copper and zinc; and, as their mutual contact produces a motion of the electric fluid from the copper to the zinc, it cannot operate as a conductor in the contrary direction. The effect is therefore only diminished in proportion as the copper spring, by placing part of the zinc plate between two copper surfaces, diminishes its electro-motive energy. This experiment appears a satisfactory proof of the electro-motive power produced by the association of the metals, and of its tendency to produce a current of electricity from one extremity of the battery to the other, and consequently a circulation of electric fluid when the opposite extremities are connected: it also proves that the electro-motive power is influenced by the nature of the substance interposed between the different pairs of metals, and thus accounts in some measure for the different effect produced by different fluids. This last circumstance is an interesting subject of enquiry; some instructive facts respecting it have been detailed by professor Berzelius, in an account of an ingenious experiment made to prove that oxidation is not the cause of the electricity of the Voltaic apparatus. The following is extracted from his description. 'I took twelve tubes of glass, half an inch diameter and three inches in height, and closed at one end. I half filled them with a strong solution of submuriate of lime (such as is obtained from the residue after the preparation of caustic ammonia), and above this fluid I poured diluted nitric acid, with the precaution not to mix the liquids. I arranged these tubes in succession, and then took copper wires, round one of the extremities of each of which I had melted zinc, in order to attach a knob of that metal to that end. I immersed the zinc-coated ends of each into one of the tubes to the bottom of the submuriate, and then bent the upper ends of the respective wires so as to immerse them in the middle of the acid of each nearest tube. This arrangment consequently formed a series in the order following: copper, zinc, submuriate of lime, nitric acid; copper, zinc, &c. It is evident that the chemical affinity which produces oxidation at the common temperature, was here at the surface of that part of the copper which was in contact with the nitric acid; and that, if this oxidation had been the primary cause of the electricity of the apparatus, the pole of copper in this construction, ought to have possessed the same electricity (namely, the positive) as the zinc pole in the common pile. Before the extremities of this small apparatus were connected, the copper continued to be constantly dissolved in the acid, which it turned blue, and the surface of the zinc remained metallic and without any perceptible change. And lastly, I combined the poles, by means of silver wires, passed into a tube filled with a solution of muriate of soda. But I was greatly surprised to find the effect directly contrary to what the theory, which considers oxidation as the cause of the electricity of the pile, had led me to expect. The solution of the copper instantly ceased, and the zinc became covered with a mass of white oxide, vegetating on all sides in the form of wool. The pole of the copper produced hydrogen gas as usual, and the zinc pole caused an abundant precipitate of muriate of silver. The electric state, therefore, produced in this case an affinity, which at the ordinary temperature of the atmosphere is inactive, and caused another very active affinity to cease, which was already in operation; and this could be effected by no other cause than that of the electricity produced by contact, which occasions the electric charge of the pile, and disposes the affinities which shall be put into activity. This little apparatus was very powerful, and disengaged so large a quantity of gas, as would not have been exceeded by 100 pairs of plates. But what could be the cause of this? I exchanged the submuriate for neutral muriate; it then produced a very moderate effect, corresponding with the number of pairs; and, lastly, I substituted neutral muriate

of zinc instead of the muriate of lime, and then the effect was scarcely perceptible, though it continued sufficient to prevent the oxidation of the copper in the nitric acid, and to show that the conductor of the zinc pole continued always to be oxidized.' This experiment demonstrates the influence of the interposed fluid on the chemical effects of the apparatus, which may probably arise from its action on the electro-motive power produced by the association of the metals. It indicates also, that the chemical action of the battery is never exerted but when the electric fluid circulates from one extremity to the other; and corresponds in this respect with an experiment by Sir H. Davy, in which forty compound arcs of zinc and silver were arranged in the usual order, in a series of glasses, filled with a solution of muriate of ammonia rendered slightly acid by muriatic acid; whilst the extreme parts remained unconnected, no gas was disengaged from the silver, and the zinc was scarcely acted upon; but when they were connected all the zinc wires were dissolved more rapidly, and hydrogen was disengaged from every silver wire. In simple Voltaic combinations, it appears essential to the production of chemical effects, that there be a transition of the elements of the interposed fluid; and, as this may be presumed to take place also in each cell of a battery, it is perhaps one cause of the superior action of those fluids which are most readily susceptible of decomposition. When for instance a compound arc of zinc and platina is placed with the platina leg in a solution of silver, and the zinc leg in dilute muriatic acid, no precipitation of silver takes place unless the glasses are connected by some fluid medium, or by a metal which is soluble in the acid of the solution of silver. With arcs of platina, or gold, therefore, no effect is produced; but, with any other metal, a portion of the silver or copper of the solution is revived, and a corresponding portion of the simple connecting arc is dissolved, and occupies the place of the revived metal in the solution. Hence the corrosion of the zinc plates in the Voltaic battery, and the liberation of hydrogen at the copper surfaces. From the phenomena hitherto described, it appears that the primary source of the electric power of the Voltaic apparatus may be considered to be the association of the metals of which it is composed; but the chemical effects, though probably arising from the same cause, are obviously influenced by the nature and action of the interposed fluid. The relation of the various parts of a Voltaic apparatus (as usually constructed), to the various effects it produces, have been developed by the masterly experiments of M. De Luc. The ordinary apparatus consists of three constituent parts, namely, two metals and a fluid, being usually, when arranged in a pile, copper or silver, zinc, and wet cloth, following each other in successive groups. Now, if these be regarded attentively, without any regard to Volta's theory, they may be considered as divided into ternary groups under three different aspects. 1. Zinc and silver, with wet cloth between them. 2. Zinc and silver in mutual contact, with wet cloth on the side of the zinc. 3. Zinc and silver still in mutual contact, but the wet cloth on the side of the silver. Either of these ternary associations may be the cause of the action of the apparatus; but the really efficient groups may be ascertained, if each of the ternary associations are successively mounted as a pile, the different groups being separated from each other by some conductor that does not materially affect their electro-motive power. M. De Luc employed for this purpose small tripods, formed of brass wire, so bent as to touch the plates between which the tripod was placed, only at the three points of support.

110. The first dissection of the pile by this method was to form an arrangement of seventy-six groups of zinc and silver with wetted cloth between them; one group being placed first (suppose with the zinc plate lowest); then upon the silver plate a tripod of brass wire; upon that another group with the zinc plate lowest; again, upon its silver, a tripod, upon that a third group in the same order, and so on until the whole seventy-six groups were arranged.

111. Under these circumstances the same chemical and electrical effects were obtained, as when the apparatus was put together without the brass tripods. It therefore appeared that the efficient groups, for all the effects of the apparatus, were an association of silver and zinc, with wetted cloth between them. To ascertain the truth of this indication, a second dissection was made. In this the two metals were placed in contact with each other, and the wet cloth in contact only with the zinc plate. Suppose a pair of zinc and silver plates in contact with each other, placed on the base of the pile with the silver lowest, then a disk of wetted cloth upon the zinc, and a tripod upon the wetted cloth; then another group of zinc and silver, with wet cloth upon the zinc; then again a tripod, and so on, in regular order, until the seventy-six groups were arranged.

112. With this apparatus the electrical effects were produced as before; but, though these ceased when the usual glass tube for decomposing water was made to connect the opposite poles, not the slightest chemical effect was produced.

113. From this it appears, that the condition for the production of chemical and electrical effects is different; the latter requiring the arrangement of silver and zinc in mutual contact, the successive pairs being separated by a moist conductor, which may be in actual contact with the zinc only; the former requiring the association of silver and zinc, with wetted cloth between them.

114. A third dissection of the pile was thus arranged: silver and zinc in mutual contact, wetted cloth in contact with silver: seventy-six of these groups were placed in regular order, with a tripod upon the wet cloth of each group, as in the former experiment. With this arrangement neither chemical nor electrical effects were produced; the absence of electrical signs M. De Luc ascribed to the zinc plates being in contact on one side with the silver, and on the other with the brass of the tripod, which he regarded as a counteracting effect. The absence of chemical signs arose from the want of the condition for

their production, namely, successive associations of zinc and silver, with a fluid between them and in contact with both.

115. When either the continuous pile, or that composed of the efficient ternary groups, are put together with the pieces of cloth moistened with pure water, although chemical effects are produced, no perceptible shock can be felt; but, when the pieces of cloth are moistened by a solution of common salt, the shock is very distinct. Hence M. De Luc concludes, that for the production of chemical effects in the circuit it is essential that the zinc undergo oxidation, and for the production of the shock it is necessary that oxidation be effected by the action of an acid.

116. M. De Luc conceived the phenomena of the pile might arise from some modification of the electric fluid which pervaded it during the oxidation of the zinc; and as, in his experiments, he obtained more perceptible electrical indications by aid of the condenser, from wires immersed in water, when the chemical effects and the shock were produced, he concluded that this modification of the electric fluid was attended by a retardation of its course, by which a very small quantity was enabled to produce effects which are not obtained by a much larger quantity when set in motion by the electrical machine.

117. This idea, it may be observed, is the very converse of that which, from a very general and extended view of the phenomena of the Voltaic apparatus, Mr. Singer proposed.

It was indeed a natural inference at first view, from the experiment in question, when that alone was considered; but the increased rapidity of decomposition, which always attends the increased operation of that influence, which is here supposed to cause a retardation of the current that occasions decomposition, is very inimical to any such supposition; and the usual phenomena of electrical analysis are equally at variance with it.

118. When any fluid is decomposed by the action of the common electrical apparatus, the effect is always proportioned to the intensity of the current of electricity that passes through it; and in the decomposition of water, when the metallic surface in contact with it is of moderate extent, very strong shocks in rapid succession are required. It is to the acute intelligence of Dr. Wollaston we are indebted for the means of executing this analysis with a more moderate power. He enclosed the metallic conductor in glass, or wax, and exposed only a very small portion of its surface to the fluid. The current of electricity, being thus reduced in volume, was proportionably increased in force; and, by rendering the exposed surface very minute, a sufficient intensity was produced, by a moderate quantity of electricity.

119. When a circuit is made through water, by wires proceeding from the opposite extremities of a Voltaic battery, those wires can impart no charge to the condenser, unless the quantity of electricity evolved by the battery is greater than the water can transmit: therefore any cause that increases the quantity, will produce an augmentation of effect by this test, whilst the column of water remains the same; or if the velocity of the electro-motion of the apparatus be increased, whilst the same imperfect conductor is interposed between its extremities, a similar effect must take place; for the positive wire will receive electricity from the pile faster than it can transmit it to the water, and the negative wire yields electricity to the pile more rapidly than it can receive it from the water; so that a slight positive and negative charge will be given to the condenser by these wires respectively, whenever the electro-motion of the pile supplies electricity faster than the water can conduct it; and the charge will be highest when the supply is most rapid. Now, according to Mr. Singer's principle, the most rapid electro-motion of the apparatus will be produced when the different pairs of plates communicate with each other through the medium of the best conducting fluids: it is therefore obvious, that the result of M. De Luc's experiments, in which a more considerable charge was communicated to the condenser by wires immersed in water, when the pile was excited by a saline solution, than when it was excited by pure water, is conformable to the above principle; and the legitimacy of this inference is confirmed by a variation of the experiments; for if, when the apparatus is excited by a saline fluid, the tube that connects its extremities be filled with the same fluid instead of pure water, no increased charge will be given to the condenser by either of the wires, because the increased electro-motion of the apparatus is then compensated by the increased conducting power of the fluid by which its extremities are connected.

120. When different degrees of chemical action are excited in the Voltaic apparatus, by the introduction of various fluids, the more powerful the action that is produced the more transient is its duration. This circumstance is of importance in the practical application of the instrument, since it offers the means of judiciously applying various methods of experiments, and of continuing the action of the apparatus during any required time. When the battery is charged with water, its chemical action is feeble, but it appears to continue without diminution for any indefinite length of time; by the addition of a minute quantity of muriatic acid, $\frac{1}{300}$th part for instance, its chemical action is greatly augmented, and still continues for a considerable period. When the proportion of acid is increased to a thirtieth or twentieth part, the action is considerable, but comparatively of short duration. Mr. Singer says, he has found no solutions so advantageous as those of acids, and he prefers the muriatic acid to all others; the nitric is indeed rather more powerful in the same proportion, but its cost is four times as great, and it is found that it destroys the copper plates as well as the zinc. The nitrous gas evolved by its action is also much more offensive than hydrogen, which results from the employment of muriatic acid.

121. The experiments of M. De Luc induced him to conclude, with Volta, that the electrical effects of the apparatus result entirely from the successive association of the different metals,

separated into pairs by some conducting substance that does not interfere with their electromotive powers. To ascertain if a liquid was essential to this effect, he mounted a pile with pieces of cloth not moistened, and he found the electric effects were still produced, but somewhat weaker than with the wetted cloth. He then instituted a series of experiments, successively mounting the pile with different animal and vegetable substances, interposed between the pairs of metal, instead of wetted cloth. Of the various substances tried, he preferred writing paper, as the most convenient of those that were efficient. The apparatus constructed in this way was found to have the same electrical indications as the common Voltaic pile, but it produced no chemical effects, however numerous the pairs of plates; nor was any oxidation of the zinc produced by its most protracted action. These circumstances led to the idea, that, by the extension of the number of groups, a kind of perpetual electric machine might be formed; and, as in the previous trials, it had been found that the effect was rather increased by pasting the paper upon the silver or copper. Dutch gilt paper, which consists of thin copper leaf, laid upon paper, was employed instead of the usual silver, or copper plates, and moist conductors: 800 plates of tinned iron being put together with the same number of Dutch gilt paper between them, the copper sides being all turned in one direction, the combination was found to affect the electrometer more powerfully than any Voltaic battery had been ever observed to do; but on the application of the usual glass tube with water, no chemical effect was noticed. The apparatus was left for a considerable time, and its action on the electrometer continued without diminution; and subsequent experience has shown that it does so for any period during which the experiment has been continued. Thus was invented a new and important Voltaic arrangement, highly valuable both in a theoretical and practical view: in the former, as separating the pure electrical effects of the Voltaic battery from its chemical power, and demonstrating the permanence of its electro-motive faculty: in the latter, as providing a spontaneous and permanent electrical machine, in which the opposite electrical states perpetually exist, without any new excitement. Besides these properties, the new apparatus promises to become an important meteorological instrument; for the degrees of its electrical indications have been observed to vary with the different seasons of the year, and are probably influenced by some of the causes by which our atmospherical phenomena are produced.

122. To distinguish this instrument from the usual Voltaic apparatus, from which it differs in many respects, M. De Luc proposed to call it 'the Electric Column,' an appellation sufficiently appropriate, since the effects it produces are purely electrical.

123. Mr. Singer made very numerous experiments, on the constructions of such columns, and varied their combinations most extensively. The materials he preferred, are thin plates of flatted zinc alternated with writing or smooth cartridge paper, and silver leaf. The silver leaf is first laid on paper, so as to form silvered paper, which is afterwards cut into small round plates by means of a hollow punch. In the same way an equal number of plates are cut from thin flatted zinc, and from common writing or cartridge paper. These plates are then arranged in the order of zinc, paper, silvered paper with the silvered side upwards; zinc upon this silver, then paper, and again silvered paper, with the silver side upwards; and so on, the silver being in contact with zinc throughout, and each pair of zinc and silver plates separated by two discs of paper from the next pair. An extensive arrangement of this kind may be placed between three thin glass rods, covered with sealing-wax, and secured in a triangle, by being cemented at each end into three equi-distant holes in a round piece of wood; or the plates may be introduced into a glass tube previously well dried, and having its ends covered with sealing-wax, and capped with brass; one of the brass caps may be cemented on before the plates are introduced into the tube, and the other afterwards; each cap should have a screw pass through its centre, which terminates in a hook outside. This screw serves to press the plates closer together, and to secure a perfect metallic contact with the extremities of the column. To fill the tube with discs, it is necessary to employ a cylindrical rammer of baked wood with flat ends, and when a small number (as about half a dozen discs) are introduced, they should be thrust down, taking care to ensure their perfect contact; and the operation of the apparatus will be ensured.

124. Soon after the invention of the column, Mr. B. M. Forster discovered that, when a sufficiently extensive series was put together, its electric power was sufficient to produce a sort of chime by the motion of a small brass ball between two bells, insulated, and connected with the opposite extremities of the column. He constructed a series of 1500 groups, and by its agency kept a little bell-ringing apparatus in constant activity for a considerable length of time.

125. Mr. Singer contrived an arrangement which is well calculated to form a perpetual motion, by excluding, to a very considerable extent, the operation of extraneous causes of interruption, and it at the same time renders the disposition of the apparatus rather elegant. A series of from 1200 to 1600 groups are arranged in two columns of equal length, which are separately insulated in a vertical position by glass pillars constructed on his principle of insulation; the positive end of one column is placed lowest, and the negative end of the other; and, their upper extremities being connected by a wire, they may be considered as one continuous column. A small bell is situated between each extremity of the column, and its insulating support, and a brass ball is suspended by a thin thread of raw silk, so as to hang midway between the bells, and at a very small distance from each of them. For this purpose the bells are connected, during the adjustment of the pendulum, by a wire, that their attraction may not interfere with it; and, when this wire is removed, the motion of the pendu-

lumn commences. The whole apparatus is placed upon a circular mahogany base, in which a groove is turned to receive the lower edge of a glass shade with which the whole is covered.

126. If a column of about 1000 series is placed horizontally, with each of its extremities resting on a gold leaf electrometer, the electrometers will each diverge; that connected with the zinc extremity of the column will be positive, that connected with the silver extremity will be negative. If the column be very powerful, the gold leaves of the electrometer will alternately strike the sides of the glass, but this motion is soon stopped by their adhering to it. If the simple divergence only is produced, on touching either extremity of the column, the electrometer connected with it closes, and that at the opposite extremity has its divergence increased. This is analogous to the effect of the Voltaic battery when disposed in a similar manner; but the motion in the column is slower, which arises from the more imperfect conductors of which it is composed.

127. There is some cause, not yet perfectly developed, that appears to influence the power of the column to produce the motion of light metallic pendula. In the bell-ringing apparatus, for instance, though the motion always continues, it is much more rapid at one period than another, and the oscillations of the pendulum, though usually as uniform as that produced by mechanism, is on some occasions singularly wild and irregular. The frequency with which the gold leaves of an electrometer strike the sides of the glass, when connected with an electric column, is also different at different times; the variations observed in some experiments of M. De Luc are much more considerable than we have yet noticed, with the more powerful columns of Mr. Singer's construction.

128. De Luc proposed, as an interesting object of enquiry, to make regular observations on the action of the column, and the number of oscillations it would produce in a given time, at each observation. For this purpose a single column of from 1000 to 2000 series may be supported vertically on an insulating pillar. A bent wire, with a ball at its lower end, is to be connected with the upper extremity of the column, so as to hang parallel with, and at some distance from it; the ball at its lower extremity being diametrically opposite to a similar ball that is screwed into the lower cap of the column. To the same cap there is also screwed a brass fork with a fine silver wire stretched between its extremities; this is placed above the ball and projects farther from the column, so that when the pendulum moves towards the ball it strikes this wire first, and receives a kind of jerk, which prevents it from sticking. The pendulum consists of a gilt pith-ball suspended by a very fine silver wire, which hangs parallel to the bent brass wire, to which it is fastened at top; the arrangement is such, that the gilt pith-ball would be always in contact with the brass ball that proceeds from the upper extremity of the column, if the apparatus had no electrical power; it therefore always returns to this situation, when, after being attracted to the lower extremity of the column, it discharges its electricity by striking against the cross silver wire.

129. There appears every reason to believe, that the action of a well-constructed column would be permanent. There is, however, a precaution necessary to their constant and immediate action; the two ends of a column should never be connected by a conducting substance for any length of time; for if, after such continued communication, it be applied to an electrometer, it will scarcely affect it for some time. It is, therefore, necessary, when a column is laid by, that it be placed upon two sticks of sealing-wax so as to keep its brass caps at the distance of about half an inch from the table, or other conducting surface on which it is laid. And if a column, which appears to have lost its action by laying by, be insulated in this way for a few days, it will usually recover its full power.

130. There is another cause of deterioration which is more fatal; it is the presence of too much moisture. If the paper be perfectly dry it is a non-conductor, and will not therefore produce any action in the column; but this perfect dryness can only be obtained by exposing the paper to a heat nearly sufficient to scorch it, and in its dryest natural state the paper will be found sufficiently a conductor, even when, by exposing the paper discs to the heat of the sun, they have been so dried as to warp considerably. When the paper is sufficiently dry, the action of the column continues without diminution; and on taking such an apparatus to pieces after it had been constructed thirty months, no trace of oxidation was evident on the zinc plates.

131. The size of the plates in the column need not be large; Mr. Singer has constructed them of various sizes, and finds no proportionate advantage by extending the diameter beyond five-eighths of an inch; they may even be constructed much smaller, and yet found to act with the greatest precision.

132. By connecting the extremities of a column of at least 1000 series, with the opposite coatings of a Leyden jar, during a period of from one to five minutes, a charge is usually communicated to it capable of affording a small but distinct spark, when the discharge is made by a wire that is not very thick.

133. Mr. Singer observes that the most extensive series he had ever made experiments with, consisted of 20,000 groups of silver, zinc, and double discs of writing paper. Its power was considerable. Pith-ball electrometers, with balls of one-fifth of an inch diameter, and threads of four inches long, diverged to the distance of two inches and upwards, when connected with its opposite extremities. An electrometer in the centre was not affected. When either extremity of the column was connected with the ground, the electrometer attached to that extremity closed, and the central electrometer opened with the same electricity, whilst that connected with the opposite extremity had its original divergence considerably increased; but the electro-motion was so slow, that some minutes were required to produce the full effect.

134. By connecting one extremity of the series with a fine iron wire, and bringing the end of

this near the other extremity, a slight layer of varnish being interposed, a series of minute bright sparks were obtained by drawing the point of the iron wire lightly over the varnished surface.

135. A jar containing fifty square inches of coated surface was charged by ten minutes contact with the column, so as to convey a disagreeable shock, felt distinctly in the elbows and shoulders, and by some individuals across the breast.

136. The charge from this jar could perforate thick drawing paper, but not a card. It had just power to fuse one inch of platina wire, of the $\frac{1}{5000}$th of an inch diameter.

137. Notwithstanding the considerable electric power of this combination, it had not the slightest chemical action; neither the best nor worst conducting media were affected. Saline compounds, tinged with the most delicate vegetable colors, were exposed under the most favorable circumstances to its action, and in some instances for many days, but no chemical effect was produced.

138. It therefore appears indispensably necessary to the chemical power of the Voltaic apparatus, that a liquid be interposed between each pair of its plates, whilst, for the pure electrical effects, the only condition appears to be the association of the two metals, and the connexion of the different pairs, by some conductor that does not interfere with their electro-motive power.

138*. The first experiments made upon the moist pile in this country appear to have been performed by Messrs. Nicholson and Carlisle. After observing the effects then ascribed to the piles on bringing the wires from each end of the column in contact with a drop of water, they observed a disengagement of bubbles of some elastic fluid.

139. On closer examination they found the gas to be hydrogen. They then took a glass tube, about half an inch in diameter, into each end of which a cork was inserted, the tube being filled with water. Through each cork was introduced a brass wire, so that the ends of the wires in the glass were about an inch and three-quarters of an inch. The pile employed consisted of thirty-six half-crowns, and as many similar pieces of zinc, and wet pasteboard. The zinc end of the pile was then connected with one of the wires in the tube, and the silver end with the other, so that the circuit formed by the pile was separated by the water in the tube placed between them. A stream of bubbles was observed at the end of the wire, in the tube connected with the silver end of the pile. No gas was disengaged from the opposite wire, but it speedily became tarnished, first of an orange color, and ultimately black. The tube was then reversed, when it was observed that the wire, which in the first experiment became tarnished, gave out bubbles, while that which had before given out gas, in its turn became tarnished.

140. The emission of gas from the wire connected with the silver end of the pile was constant and uniform, except when a metallic circuit was formed between the ends of the pile, during which no gas whatever appeared. It was observed that, when this metallic conductor was removed, the appearance of the gas was not immediate, since there was an interval of about two seconds between the removal of the wire and the appearance of bubbles. After the process had continued two hours and a half, a bulk of gas was produced equal to two-thirds of a cubic inch. This gas was mixed with an equal bulk of common air, and exploded on the application of a lighted taper.

141. These ingenious experimenters, supposing the phenomena in question to arise from the decomposition of the water, thought it surprising that the hydrogen should make its appearance at a distance of an inch and three-quarters from the point where the oxygen was disposed of.

142. They then made the same experiment with a tube thirty-six inches in length, but no gas was observed. When they introduced an infusion of litmus instead of pure water, they observed that the fluid in the vicinity of the wire connected with the zinc end of the pile became red, and hence were led to suppose that an acid had been produced. The fluid at the other wire was not changed, but gas, as usual, was evolved.

143. It may be proper to state that, in every apparatus constructed for practical purposes, there is a combination of three different substances in contact with each other, in successive groups; in general it is an arrangement of copper, zinc, and some conducting fluid. It is demonstrable that the primary source of the electrical power of the apparatus is the association of the two metals; and, according to Volta, the interposed fluid serves only as a conductor of the effect of one pair of metals to another. As far as electricity is concerned, this opinion appears to be correct, for the electrometer is acted on, whatever be the nature of the interposed fluid, and the degree of divergence is proportioned to the number of the plates. The electrometrical effects prove also, that, the arrangement of a series of zinc and copper plates, with an interposed fluid, forms a conducting column, which, in its insulated state, is positive at one extremity, negative at the other, and neutral in the middle. This may be easily shown by three gold-leaf electrometers, connected at the same time with an apparatus of 300 or 400 pairs of plates. The electrometer, connected with the copper extremity, will diverge with negative electricity; that connected with the zinc end will separate to the same distance positively; while that connected with the central plate of the series will not be affected. But, if either extremity of the battery be connected with the ground by means of a wire, the leaves of the electrometer connected with it will close; and those of the central electrometer will open with the same electricity, and to the same extent, whilst those of the opposite extremity will have their original divergence increased.

144. Hence it appears that there is a real electro-motive property in the apparatus, by which the zinc end constantly tends to become positive, and the copper end negative; and it is also obvious, that the extent of this operation,

at either extremity, is increased by connecting the opposite end with the ground. This last experiment, by which the central plate may be rendered either positive, negative, or neutral, at pleasure, proves also that the interposed fluid never acts as an insulator, for if it did so these changes could not possibly occur.

145. As the contact of either surface of the battery with the ground increases the electrical state of the opposite extremity, the same circumstance may be presumed to take place with every pair of associated metals, when their surfaces are in contact with a conducting fluid. Whilst the apparatus is insulated, the first zinc plate can only act on the electricity of its associate, the first copper plate; but the second zinc plate, through the conducting interposed fluid, can act on both these, besides its companion, the copper, and may therefore become more highly positive; and it is easy to conceive that such a repetition of action would be attended with an increase of effect, proportioned to the number of plates; and that the electrical tension of either end must be increased by connecting the other with the ground.

146. To ascertain if this principle really operated with a single combination, Mr. Singer took a pair of circular plates six inches diameter, very clean and smooth, one being formed of zinc and the other of copper, and each provided with an insulating handle. When both plates were held by their insulating handles, and the zinc was successively applied to the flat surface of the copper, and after each contact made to touch the insulated plate of a condenser of six inches diameter; twenty contacts were required to communicate such a charge to the condenser as would occasion the leaves of a very delicate electrometer to separate to a quarter of an inch. But when the copper plate, instead of being held by its insulating handle, was simply laid on the hand, or on any similar conducting body, ten successive contacts of the insulated zinc plate, communicated a charge to the condenser, which occasioned the gold leaves to separate to the distance of more than half an inch. On repeating these experiments, with the variation of touching the condenser with the copper plate, held by its insulating handle, and brought in contact with the zinc plate, first insulated, and then uninsulated, similar results were obtained, but with the contrary electrical state. Hence the similarity of action in a single pair of metals, and a combined series, is sufficiently proved; and the preceding statement of the manner in which the electrical power is supposed to increase with the number of associated plates, is rendered highly probable.

147. So far the phenomena are sufficiently simple and consistent, for those described are not materially influenced by the nature of the interposed fluid, nor do they occur, but when the extremities of the apparatus are unconnected with each other, and consequently capable of maintaining the opposite electrical states. But the chemical effects, the shock, and the power of ignition, take place only when the extremities of the apparatus are connected by some conductor, and are also materially influenced by the nature of the interposed fluid. If these effects then, are produced by electricity, they can only result from its circulation in the apparatus; and, as there is no reason to suppose that the electro-motive power of the associated metals ceases when there is a conducting communication between their opposite surfaces, but rather that it is accelerated by such a circumstance; that very acceleration may be the cause of the phenomena, and the effects observed correspond very nearly with such an idea; for, if it be admitted that the connexion of the opposite ends of the Voltaic battery by a conductor, occasions a current of electricity from the positive to the negative, that current must be more rapid, in proportion as the conductor is more perfect. Now it is found that the chemical effects are most considerable, and more promptly produced in fluids of the highest conducting power; thus the quantity of gas liberated in a given time from common water, is greater than from distilled water; saline fluids furnish more than common water; solutions of alkali more than saline fluids, and acids more than alkalies: and, as the effects of a simple combination are influenced by the same causes as those that operate with a series, the fluids that are susceptible of the most rapid decomposition are also most active in exciting the chemical effects of the battery, when employed as the connecting medium between its plates.

148. Acids are of all other fluid bodies, excepting metals, the most perfect conductors, and the chemical effect of the battery is more powerfully excited by them than by any other substances; it is possible that their chemical action on the zinc may have some share in modifying the quantity of electricity, or the rapidity of its motion; but it is certain that the effects are not in proportion to the chemical action; sulphuric acid, for instance, acts as powerfully on the zinc as nitric or muriatic acid, but it is not so active in producing the chemical agency of the battery: in like manner the alkalies, which exert a very trifling action on the battery, excite its powers with greater energy than many saline fluids which are more efficient as chemical agents.

149. The ignition of wire, and of charcoal in the Voltaic circuit, is conformable to this view; these substances are the most perfect conductors known, and, when made the medium of communication between the opposite ends of a battery, must accelerate its electro-motive power to the greatest extent. The rapid circulation of electricity, thus obtained, produces ignition, if the conductor be not too large in proportion to the quantity of electricity; but, within this limit, the effect will be greatest with the thickest wire, because the acceleration will be more considerable in proportion to the facility of transmission. There is, perhaps, no other view on which the continued ignition of wire, and the increased action of large plates is so intelligible.

150. The cessation of chemical agency, and igniting power, as the chemical action of the acids or other menstrua declines, may arise from the total change which then occurs in the nature of those fluids; their conducting power is much diminished, and they may possibly, by the change

in their chemical properties, acquire some faculty of electro-motion subversive of the effect of the combined metals.

151. The extensive experiments of Messrs. Hisinger and Berzelius, confirmed by the researches of Sir H. Davy, had demonstrated the constant separation of oxygen, and compounds in which it prevailed, at the wire proceeding from the zinc surface, and of hydrogen and other inflammable matter, at that connected with the copper surface; and, at this latter, alkali was also frequently found, and, from analogy, it was in consequence concluded, that the alkalies probably contained a considerable proportion of some inflammable substance.

152. This conjecture was confirmed by Sir H. Davy in 1807: he found that a thin piece of potassa or soda, slightly moistened by exposure to the air, and placed between two conductors of platina, proceeding from the opposite sides of a powerful Voltaic apparatus, was resolved into a peculiar metallic substance highly inflammable, which appeared at the negative surface; and oxygen gas, which was evolved at the positive surface. By an extensive series of experiments, it was shown that these bodies are, in reality, metallic oxides, and that the proportion of their constituent parts is somewhat different, being in round numbers, for potassa six parts of metallic base to one part of oxygen, nearly; or it may be stated that potassa is composed of eighty-six parts of metal, and fourteen of oxygen in each 100 parts. The proportions in soda are nearly seven parts metal to two of oxygen; or seventy-eight metal and twenty-two oxygen, in each 100.

153. The metal obtained from potassa is called potassium; it is lighter than water in the proportion of eight to ten. At common temperatures it is solid, but soft and plastic. At a temperature of 150° it becomes fluid, and evaporates at a heat rather below redness. In color it nearly resembles silver, but it tarnishes immediately when exposed in the open air, and can only be preserved under naphtha. Its attraction for oxygen is so powerful, that it will detach that substance from almost all its combinations; and the result of this action is its consequent oxidation and reconversion into potassa. If thrown into water it immediately inflames, floats upon the surface, and burns with a mixed flame of white, red, and violet; rendering the water, in which the experiment is made, alkaline. Similar phenomena ensue when it is brought in contact with ice. When moderately heated in oxygen gas it inflames and reproduces potassa. Its action on water is always attended by the decomposition of that fluid; hydrogen is evolved, and the oxygen combines with the potassium to form potassa. By measuring the quantity of hydrogen separated from water, by the action of a given weight of potassium, the quantity of oxygen that metal combines with to form potassa may be readily learnt. Each grain of potassium detaches about 1·06 cubic inch of hydrogen gas, and consequently combines with half that quantity of oxygen.

154. The metal obtained from soda is named sodium; it is rather lighter than water, nearly as 0·9348 to 1000. It has the color of silver; is less fusible than potassium, but tarnishes in air in the same way. It is fluid at the temperature of 200°, and passes into vapor at a strong red heat. At common temperatures it is a soft metal, and a globule of it may be easily spread into a thin leaf by the action of a knife. It decomposes water violently, and floats on its surface, but does not inflame; the water is rendered alkaline, and, when examined, is found to contain pure soda. It acts nearly in the same manner as potassium, but with less energy, on most substances, and must consequently be preserved under naphtha. When thrown on the surface of nitric acid it inflames, and burns with great brilliance; it also occasionally scintillates when thrown upon hot water. The proportion of oxygen with which it combines to form soda, may be learnt by noting the quantity of hydrogen evolved from water by a given weight of the sodium.

155. Both these new metallic substances unite with mercury in various proportions, and form amalgams which decompose water, but more slowly than the metals themselves; these amalgams act upon all other metals, even platina and mercury.

156. The decomposition of the alkalies may, by care and attention, be effected with a battery of fifty pairs of plates of three or four inches square; but the results are rather uncertain: 200 plates form a very efficient arrangement; they should be excited by a weak acid mixture (about one part strong muriatic or nitrous acid, to thirty parts of water). A plate of silver or platina being connected with the negative side of the battery, a thin piece of pure potassa or soda is to be placed upon it, and a platina or silver conductor, proceeding from the positive side of the battery, is to be brought in contact with the upper surface of the alkali, which soon fuses at the points of contact: metallic globules shortly appear near the negative surface, and gradually increase in size, until a crust of alkali begins to form on their surface; at this moment they should be removed by the point of a knife, and instantly plunged under naphtha; or, if the experiment be merely intended to demonstrate their production, they may be brought in contact with the surface of water or nitric acid. It sometimes happens that no globules appear; but if the contact be preserved for some time, and the alkali be afterwards raised, several will be found imbedded in its under surface. If the action of the battery be strong, it also sometimes happens that the globules inflame, and even detonate at the moment of their production; it is therefore advisable not to bring the eyes too near during the experiment, or else to cover them with glasses. These experiments always require great care to insure their success, which a trifling variation in the power of the battery, purity of the potassa, or moisture of the atmosphere, may prevent.—Soda is rather more difficult to decompose than potassa, and therefore requires to be employed in thinner pieces; the pieces of potassa should rarely exceed a quarter of an inch in thickness, and those of soda one-eighth of an inch.

157. To prevent the loss of the alkaline bases during their separation, by the powerful action of the air upon them, it has been proposed to effect

the decomposition under naphtha: the moist potassa being placed between two plates of platina in a proper vessel, which is to be filled with naphtha as soon as the contact with the battery is established; in this way the action of the air is prevented, but the naphtha decomposes, and hydrogen and charcoal are liberated, which renders the result less satisfactory than in the more simple form of the experiment. The most essential precautions are to preserve the alkali as dry as is consistent with a sufficient degree of conducting power, and to employ the battery in a moderate state of action, in which it does not produce a very intense heat, for that would destroy the metallic base at the moment of its production.

158. The amalgam of potassium, or sodium, with mercury, is easily procured; and may be obtained by a very moderate power. A glass tube, one-fourth of an inch diameter and three inches long, having a short platina wire sealed in one end, is to have mercury poured into it until the end of the platina wire is covered; the rest of the tube is to be filled with a concentrated solution of alkali, either pure or carbonated. The platina wire, surrounded by mercury, is then to be connected with the negative end of a Voltaic battery, and the circuit completed by bringing a platina wire from the positive end, in contact with the solution of alkali. Gas will be evolved from this wire, and the surface of the mercury will be greatly agitated; when the action grows weaker, the mercury may be poured into a glass of water, and the presence of the alkaline metal will be immediately indicated by the evolution of a cloud of minute bubbles of hydrogen gas, which may be collected by inverting over the mercury a small closed glass tube filled with water. This result has been frequently obtained with a battery of thirty pairs of plates of only two inches square.

159. The amalgam may be obtained more highly charged with the alkaline metal by employing a solid piece of alkali, with a small cavity on its surface, in which a globule of mercury is to be placed. The alkali is to be connected with the zinc surface of a battery, and the mercury with the copper surface; the mercury soon becomes more tenacious, and sometimes is converted into a soft solid mass, and in this state, if thrown into water, it produces a rapid decomposition.

160. The strong attraction of the metals of the alkalies for oxygen, renders them most active agents of chemical decomposition; by the strongest Voltaic power they can only be obtained in small quantity; and for the purpose of experiment they are now usually procured by another process first devised by the French chemists. A gun-barrel is bent nearly in the form of the letter S. An iron tube of the capacity of two cubic inches, having a small hole at the lower extremity and an iron stopper at the top, is ground into one end of the gun-barrel, and a tube of safety is fitted to the other. The iron tube is to be filled with pure dry potassa, and the bent part of the gun-barrel nearest to it, with clean iron turnings: this part of the barrel is to be luted and placed in a small blast furnace; the iron tube projecting out on one side, and the vacant part of the gun-barrel, with its attached tube of safety, charged with clean oil, or naphtha on the other. A strong heat is then to be raised in the furnace, and, when the iron turnings have attained an intense white heat, a small furnace is to be applied to the tube containing the potassa, which, being readily fused, will flow through the small hole at the bottom of the tube upon the iron turnings. The oxygen of the potassa combines with the heated iron, and the potassium condenses in brilliant laminæ in the vacant part of the gun-barrel, which must be kept cool by ice during the process. As potassa always contains water, that is also decomposed, and hydrogen escapes during the experiment, from the tube of safety; the cessation of this liberation of gas is the sign for removing the small furnace from the tube, and the heat being raised in the blast furnace for a few minutes, as high as possible, to expel the last portions of potassium from the iron, the whole apparatus is suffered to cool. The gun-barrel is then to be cut at the commencement of the part which has been kept cool, for there the greatest portion of potassium is usually found; it must be detached by a chisel in as large pieces as possible, and introduced quickly into naphtha, a portion of which fluid it is expedient to pour into the barrel as soon as it is first opened.

161. This process is attended with some difficulty, but it has been repeated successfully by many chemists in this country: a more detailed account of it may be consulted in the thirty-second volume of the Philosophical Magazine, pp. 89, and 276.

162. The composition of the fixed alkalies was entirely unknown before these experiments, but the volatile alkali, or ammonia, had been shown to consist of hydrogen and nitrogen, in the proportion of three of hydrogen to one of nitrogen by volume. Now it is singular, that of three bodies, whose properties are so analogous, two should be metallic oxides, and a third a compound of two gases; but there are experiments that seem to prove that either one or both of these gases contain a metallic substance, and that consequently ammonia may be, like the other alkalies, a metallic oxide.

163. Messrs. Berzelius and Pontin of Stockholm, discovered that when mercury is placed in a Voltaic circuit with a solution of ammonia, the mercury being connected with the copper-extremity of the battery, and the ammonia with the zinc, the mercury gradually expands to four or five times its original volume, and becomes a soft solid, nearly of the consistence of butter, having its metallic character quite unimpaired. It is very remarkable, that by this change it gains only about $\frac{1}{12000}$ part of its weight; yet has its specific gravity so much diminished, that, from being thirteen or fourteen times heavier than water, it becomes only three times heavier. By a short exposure to the atmosphere, it regains its original size and fluidity, absorbing oxygen and reproducing ammonia. When thrown into water a similar effect is produced, the water being decomposed and hydrogen liberated.

164. These phenomena are very analogous to those observed with the fixed alkalies; some substance combines with the quicksilver and alters its properties materially, without imparing its metallic character; now, according to all existing analogies, this substance must be a metal, and this metal, in returning to the state of alkali, absorbs oxygen, as is seen by its action on water. Hence it appears that ammonia consists of oxygen and a peculiar metal which may be called ammonium; but its analysis by other means evinces only the two gases, hydrogen and nitrogen; the former of these being the lightest of all gravitating bodies, is most probably a simple or elementary substance; and, on such a view, it would seem that nitrogen, though a gaseous body, is a compound of oxygen and a metal.

165. The amalgam of ammonium may be formed most readily by making a cavity in a moistened piece of muriate, or carbonate of ammonia, connected with the positive side of a Voltaic battery, and inserting in it a globule of mercury connected by a platina wire with the negative surface; in a few minutes a soft amalgam is formed; it must be transferred into water as quickly as possible when its action on that fluid is to be observed, as it changes by the shortest possible contact of the air.

166. Sir H. Davy has observed, that the strong attraction of potassium for oxygen, enables it to decompose ammonia even more rapidly than the Voltaic battery; and if an amalgam of potassium and mercury be placed in a cavity in moistened muriate of ammonia, it immediately increases in size, and becomes more consistent.

167. As some of the substances called earths resemble the alkalies in various properties, it was conjectured, that they also were metallic oxides; and this conjecture has been partly verified by the experiments of Messrs. Pontin and Berzelius, and Sir H. Davy. If a paste be formed with water, and either barytes, strontites, lime, or magnesia; and this paste be connected with the positive side of a Voltaic battery, and touched with an iron wire proceeding from the negative surface, the wire obtains the property of decomposing water.

168. If a globule of mercury be placed in a cavity in the earthy body, and touched with a wire proceeding from the copper end of the battery (the paste being connected with the zinc), an amalgam will be soon formed, which has the property of decomposing water, and forming with it a solution of the earth employed. If this amalgam be introduced into a little tube made of glass, and bent in the form of a retort, then filled with the vapor of naphtha and hermetically sealed; on the application of heat to the end of the tube containing the amalgam, the mercury will distil over and leave the pure metal of the earth behind. This process is rather difficult, and requires great care.

169. The amalgam from barytes, strontites, and lime, may be obtained with a battery of from 100 to 200 four-inch plates, in a moderate time; that from magnesia requires a longer continuance of the action of the battery, and the other earths do not readily yield to its powers. These metals are named from the earths of which they appear to be the bases, as follows: namely, that from barytes, barium; strontites, strontium; lime, calcium; magnesia, magnesium; alumine, aluminum; silex, silicum, &c.

170. The decomposition of the alkalies and earths which had previously resisted every attempt at analysis, are a monument of the importance of the Voltaic apparatus as an instrument of chemical research; and a proof of the ability with which it has been employed, which will be regarded with admiration and applause as long as science shall continue to be cultivated.

171. The phenomena that have been described as the consequences of Voltaic decomposition obtain in every variety of experiment. Sulphuric acid introduced into the Voltaic circuit gives off oxygen gas, and sulphur is deposited. Phosphoric acid evolves oxygen gas, and phosphorus combines with the negative wire. Ammonia separates into hydrogen and nitrogen with a small proportion of oxygen. Oils, alcohol, and ether, when acted on by a powerful battery, deposit charcoal, and give off hydrogen, or carborated hydrogen. And professor Brande has shown that when animal fluids containing albumen, are placed in the Voltaic circuit, the albumen is separated in combination with alkali at the negative wire, and in combination with acid at the positive wire; and that, with a powerful battery, it separates at the negative wire in the solid form; and with a less power, in the fluid form, so that it is probable animal secretion may depend on some such power.

Prior to an examination of the Voltaic apparatus there are some simple experiments that should be noticed.

172. If a wire of silver, and another of zinc, be immersed in a glass containing dilute muriatic acid, so as to remain at a little distance from each other, the zinc will give off hydrogen gas rapidly, but the silver will produce no effect. Bring the ends of the wires that are out of the acid in contact, by twisting them together; the quantity of hydrogen given off by the zinc will be diminished, and bubbles will be evolved from the silver.

173. If zinc, iron, or copper, are employed in the same way with gold, in dilute nitric acid, similar phenomena ensue, but the gas produced is nitrous gas.

174. If a wire of iron and another of silver are immersed in a solution of copper, the iron will soon become coated with copper, but the silver will remain unchanged. Bring the wires in contact, by twisting their upper extremities together, and the silver will be soon covered with a coat of copper.

175. Similar experiments may be made with a zinc and a silver wire, in solutions of lead or tin.

176. Dr. Wollaston, to whom we are indebted for the last two experiments, thus accounts for the result:—'We know that when water is placed in the circuit of conductors of electricity, between the two extremities of a pile, if the power is sufficient to oxidate one of the wires of communication, the wire connected with the opposite extremity affords hydrogen gas.

177. 'Since the extrication of hydrogen in this instance is seen to depend on electricity, it is probable, that in other instances, electricity may be also requisite for its conversion into gas. It would appear, therefore, that in the solution of a metal, electricity is evolved during the action of the acid upon it; and that the formation of hydrogen gas, even in that case, depends on a transition of electricity between the fluid and the metal.

178. 'We see moreover, in a former experiment, that the zinc, without contact of any other metal, has the power of decomposing water; and we can have no reason to suppose that the contact of the silver produces any new power, but that it serves merely as a conductor of electricity, and thereby occasions the formation of hydrogen gas.

179. 'In the last experiment, also, the iron by itself has the power of precipitating copper, by means of electricity evolved during its solution; and here likewise the silver, by conducting that electricity, acquires the power of precipitating the copper in its metallic state.'

180. The experiments of this ingenious philosopher, by which the attraction of alkali, and the precipitation of copper on the surface of silver, were produced by the influence of negative electricity, excited by the ordinary machine, were considered by him as favoring the preceding explanation, and proving that oxidation must be the primary cause of electric phenomena. To Mr. Singer, who furnishes the quotation, they did not appear to favor any such supposition, but rather the contrary; for in the experiment with two different wires, touching each other, both produced the same chemical effects, yet, observes Mr. S., 'if they are electrical at all, the one is positive and the other negative, as all experiments on the association of different metals prove; and if two wires that have no chemical action on the fluid in which they are immersed, be rendered respectively positive and negative, they are well known to produce different chemical effects.'

181. But it is said the chemical effect produced by the silver wire, arises from electricity communicated to it by the zinc; and that we have no reason to suppose that any new power is produced by the contact of the metals. Now, if this were the case, the mere conducting communication of the metals would be the only condition necessary to give the silver its chemical power; but the case is widely different, the communication must be not only conducting, but metallic, and even then no chemical effect will be produced, unless the extremities of the wires are immersed in the same liquid, or in two separate portions of liquid that have a conducting communication with each other.

182. Place two glasses filled with a solution of copper near each other. Make a compound arc, by twisting together the end of a wire of zinc, with the end of a similar wire of silver. Connect the two glasses by placing the silver leg of the arc in one, and the zinc in the other. The zinc will immediately attract copper from the solution, but it does not communicate that power to the silver, though they are both closely connected. Whilst the compound arc remains, connect the two glasses by a second arc, formed of a piece of bent wire of any kind, except gold or platina. The silver will be immediately covered with a coating of copper, and will continue to separate copper from the solution as long as the disposition of the apparatus remains the same. Now the only difference in the arrangement, that appears to have operated as a condition to the chemical power of the silver, was the provision of another conducting communication between the glasses, in addition to that established by the compound arc; it therefore appears, that the associated metals cannot serve as conductors to the effect produced; and indeed, if they did, it would be scarcely possible any accumulation of power could result from the increased number of plates in a Voltaic battery.

183. This experiment does not display any of the electric powers of a Voltaic combination; but it shows that the association of three different substances is essential to the chemical agency of such a combination; and the phenomena will be found to correspond with some experiments of M. De Luc, on the efficient groups in the Voltaic pile. This celebrated philosopher found that no chemical effects were produced by any Voltaic arrangements, unless two metals were employed with a liquid between them; and, in the experiment last described, zinc, silver, and a metallic solution were inactive, though in contact with each other, until the fluid was made the medium of conducting communication between the free extremities of the combined metals.

184. The experiment last described will succeed, when the two glasses containing the metallic solution, are connected by any moistened conductor; but the chemical power of the silver wire will be evinced slower, in proportion as the length of the moistened conductor is increased; and in all experiments of the kind, the less the interval between the extremities of the compound arc, the more rapid is its action on the interposed fluid. Hence, in the arrangements of Voltaic apparatus, for the purpose of chemical decomposition, the ends of the conducting wires are placed at a greater or less distance from each other, in proportion as their action is required to be more or less intense.

185. The arrangement of a simple Voltaic combination, by Mr. Sylvester, in which this effect is apparent, may be referred to. It consists of a tall glass jar filled with very dilute muriatic acid. Through a cork, placed in the neck of this jar, two wires are inserted; the one a short straight wire of zinc, the other a long bent wire of platina, or silver; by turning this last round, its upper end may be brought in contact with the zinc, or separated from it at pleasure. When they are separate, the zinc only is acted on; but, as soon as they are brought in contact, the platina or silver becomes covered with bubbles of gas, which appear soonest, and are evolved in the greatest quantity, from the projecting point.

186. Notwithstanding this circumstance, the power of a simple Voltaic combination con-

tinues to exert its effect, when the stratum of interposed fluid is considerable. If a tube of three feet long be filled with dilute muriatic acid, and a wire of platina be inserted through a cork in one of its extremities, and a wire of zinc in the other; on connecting the wires, gas will be soon evolved from the silver. If the tube be bent the effect will take place more slowly. Mr. Singer took two similar tubes of eighteen inches long, and connected them by a short piece of flexible pipe, so as to form together a tube of three feet in length, with a joint in the middle, which admitted of its employment either as a straight tube, or as a siphon with a bend of any required inclination. In the open ends of this tube he placed respectively a zinc, and a platina wire; and found that, whenever their outer ends were connected by a wire, hydrogen was soon evolved from the platina; but this effect took place soonest when the tube was straight, and hence it appears that the power put in motion by these combinations, can pass more readily through any given column of a fluid in a straight line, than in any other direction.

187. It has been seen, that, when any metal is in solution in the interposed fluid, it is revived by the wire which in other cases evolves hydrogen; and it has been shown, by the effect of the silver and the platina wire, that metals which have no chemical action on the interposed fluid alone, may decompose it when combined with another metal. These facts, though far from being perfectly understood, may serve to explain some chemical effects which were before rather obscure. If a zinc wire, for instance, be immersed in a solution of lead, the latter metal will be revived in the form of a metallic vegetation, which increases gradually by additions to its extremities. The first separation of the lead is sufficiently intelligible; the acid in which that metal is dissolved, having a stronger attraction for the zinc, dissolves a portion of it, and deposits on its surface an equal portion of lead. But the lead, so revived, continues to revive more, and to receive additions at its remote extremities, whilst it would have been rather expected these additions would have been made on the zinc, and the vegetation that had been first formed protruded further into the fluid by that means. The contrary result is now understood to be obtained, by the revived particles of lead forming a Voltaic combination with the zinc and the surrounding fluid. This effect is analogous to that which obtains in various other instances.

188. Spread a few drops of a solution of silver upon a pane of glass, and place a small piece of platina, and a similar piece of copper wire upon it, at a little distance from each other. A vegetation will take place about the copper wire; but no effect will be produced by the platina. Bring the wires in contact with each other, and the Voltaic combination thus formed will occasion a beautiful vegetation of metallic silver to surround the platina wire.

189. With a solution of tin, and wires of zinc and platina, similar phenomena occur; but a considerable time elapses, after the contact, before the vegetation appears round the platina. The immediate contact of the oxidable metal with the metallic solution is not absolutely necessary to the success of these experiments; it is only essential that a regular Voltaic circle, consisting of two different metals and a moist conductor be established.

190. If we take a glass tube having a piece of bladder tied over its lower extremity water tight, and a cork inserted in its upper end with a platina wire passing through it; and the tube be filled with acetate of lead, and placed in a small cup of zinc containing dilute muriatic acid; we shall find that, when a metallic communication is formed between this cup and the platina wire, the latter will become studded with brilliant crystals of metallic lead. In this case the oxidable metal has no connexion with the metallic solution but through the medium of the platina wire on the one side and moist bladder on the other.

191. Fill two similar glasses, the one with a solution of silver, the other with dilute muriatic acid; connect them by a compound wire arc of zinc and platina; the zinc being plunged in the muriatic acid, and the platina in the metallic solution. Immerse a second arc, formed of a bent silver wire, in the two glasses, one of its legs being in each; after some time the zinc wire will be entirely dissolved, and the platina will be found covered with minute crystals of metallic silver, displaying a very beautiful appearance under the microscope.

192. Copper and zinc are the metals most usually employed in the construction of Voltaic apparatus, for their effects are greater, in proportion to the value of the metals, than those of any other combination. Silver and zinc, or gold and zinc, would be more powerful, but not so much so as to compensate for the increased expense.

193. As the effects produced by a single pair of metals, of any size, are still exceedingly feeble, attempts were made to combine the action of several pairs. Professor Robinson arranged a series of zinc and silver plates, about the size of a shilling, so as to form a rouleau; and on applying his tongue to the edge of this, the sensation experienced was more manifest than by a simple pair of metals; but its power in other respects did not appear more considerable. In this arrangement every zinc plate was necessarily between two silver plates, and every silver plate between two of zinc, with the exception of the first and last. Now it has been stated, that the contact of zinc with silver, or copper, occasions some electric fluid to flow from either of those metals to it; and, consequently, when a single pair of metals are associated, the outer surface of the zinc appears positive, and that of the silver or copper negative. But if both surfaces of the zinc are in contact with copper or silver, electricity will flow into it in contrary directions, so that neither surface can exhibit the effect; and the same circumstance occurs, in a contrary order, when both surfaces of a silver or copper plate are in contact with zinc. Hence every arrangement of this kind, however numerous the pairs of metal, will exhibit at its opposite extremities the powers of a single pair of metals only.

194. Volta had the penetration to ascertain the cause of this defect in the rouleau of professor Robison; and his ingenuity supplied a means of obviating it. His experiments on the combination of two metals with an imperfect conductor (as water or saline fluids) had taught him that the electro-motive power of these fluids interfered but little with the more powerful energy of the combined metals; and that in fact they acted principally as conductors to that energy. He therefore interposed imperfect conductors of this kind between a series of pairs of metal, and thus combined their power without producing a counteracting current; for the zinc and silver, or zinc and copper, were then in contact with each other at one surface only, but the conducting communication existed throughout.

195. To construct an apparatus of this kind, procure a number of plates of zinc and copper, or zinc and silver, either round or square, of any size; and an equal number of pieces of cloth, leather, or pasteboard, of the same form, but rather smaller. Soak these last in salt water, until they are thoroughly moistened; place a plate of silver, or copper, upon the table, then upon that place a piece of zinc, and on the zinc one of the moistened discs; upon this a second series of silver, zinc, and moistened cloth (or pasteboard) in the same order; and thus consecutively until a series of fifty or sixty repetitions have been placed one upon the other. Particular care must be taken to place the plates in regular order; if in the first group silver is placed lowest, zinc next, and then the moistened disc, the same disposition must be observed throughout.

196. The Voltaic pile being thus formed, let the operator moisten both his hands with brine, and grasp a silver spoon in each. If the top of the pile be then touched with one spoon, and the bottom with the other, a distant but slight shock will be felt at every repetition of the contacts. This shock resembles very nearly the sensation produced by a very large electrical battery weakly charged; it is greater in proportion to the number of groups of which the pile is composed. If the communication is made with any part of the face near the eyes, or with a silver spoon held in the mouth, a vivid flash of light is perceived at the moment of contact, and that whether the eyes be open or shut.

197. The power of an apparatus of this kind continues for some time, but gradually diminishes, the zinc surfaces becoming oxidated by the action of the moisture; it therefore requires to be taken to pieces and cleaned, an operation that is very troublesome when the number of plates is considerable. This inconvenience was diminished by soldering each pair of zinc and copper plates together, instead of simply laying them on each other; and a further improvement was devised by Mr. Cruickshanks, which consisted in cementing the pairs of plates in regular order, in grooves made in the side of a mahogany trough, so as to form water-tight cells between each pair. These cells being filled with water, or any conducting fluid, served as a substitute for the moistened discs used in the pile; and, as the fluid could be easily poured out and replaced, it required considerably less time to keep it in proper order. This form of the apparatus, which is called the Voltaic trough, or battery, has been much used in this country; it is perhaps, on the whole the best arrangement hitherto devised, and its construction is sufficiently simple.

198. The zinc plates are made by casting that metal in an iron or brass mould; they may be about an eighth of an inch thick. The copper need not exceed twelve or fourteen ounces to the square foot, and may be soldered to the zinc at one edge only, the other three being secured by cement in the trough.

199. The trough must have as many grooves in its sides as the number of plates it is intended to contain, which should be fewer in proportion to their size, otherwise the apparatus will be inconvenient from its weight. When the plates are not more than three inches square their number in one trough may be fifty, and the distance of the grooves from three-eighths to half an inch. The trough must be made of very dry wood, and put together with white lead or cement. The plates being placed to the fire, the trough is to be well warmed, and placed horizontally on a level table, with its bottom downwards, very hot cement is then to be poured into it, until the bottom is covered to the depth of a quarter of an inch. During this process the plates will have become warm, and they are then to be quickly slided into the grooves and pushed firmly to the bottom, so as to bed themselves securely in the cement. In this way the plates are very perfectly cemented at the bottom, and, when this cement is sufficiently cool, a slip of thin deal is to be slightly nailed on the top edge of one of the sides of the trough, so as to overhang the inner surface about a quarter of an inch. The trough being about three quarters of an inch deeper than the diameter of the plates, there will be an interval between their top edges and the deal slip; and, when the side of the trough to which the slip is attached is laid flat upon the table, this interval forms a channel into which very hot cement is to be poured, and it will flow between each pair of plates, so as to cement one side of all the cells perfectly. As soon as the channel is quite full of fluid cement, the strip of deal is to be torn off, and the trough inclined so as to admit the superfluous cement to run out. When this is effected, and the cement cool, a slip of deal is to be nailed on the opposite side and the same process pursued with that. The instrument will then be cemented in the most perfect manner, and it may be cleaned off and varnished.

200. We may notice the preparation of electrical cements. The various cements employed in the construction of electrical apparatus are formed principally of resin, with the addition of some substances to render it more adhesive, and less brittle. Five pounds of resin, one pound of bees'-wax, one pound of red ochre, and two table spoonfuls of plaster of Paris, when melted, and well incorporated together, form a very good cement for general purposes. One that is well adapted for cementing large Voltaic batteries, and which is cheaper, may be formed of six pounds of resin, one pound of red ochre, half a

pound of plaster of Paris, and a quarter of a pint of linseed oil. Other cements in great variety, more or less fusible, &c., may be formed by combining the preceding ingredients in various proportions. The ochre and plaster of Paris should be well dried, and added to the other ingredients when they are well melted.

201. It must have occurred to those engaged in a series of Voltaic experiments, to observe the early exhaustion of power and the inequality of the action under the usual construction and management of the apparatus. The lecturer on this subject has more particularly felt such inconvenience; as during the progress of his experiments of elucidation he is obliged frequently to pause for explanation, during which time the power is on the decline.

202. To obviate these difficulties, Mr. Pepys has constructed a table, with drawers containing a suite of troughs, all the plates of which may be either raised out of the acid, or immersed into it, simultaneously. By means of a lever and counterpoise weight, the whole of the plates are as easily elevated as one series; all the communications with the prime conductors being, as in the same gentleman's Voltaic discharger, completed by quicksilver.

203. The troughs being enclosed within the table or chest, prevents the free escape of the acid vapors; and, where an opportunity offers of communication with a chimney or window, a pipe may be usefully added to carry them off.

204. Fig. 1, plate I., Electro-Galvanism, represents the external figure of the case.

205. Fig. 2. The internal arrangement of the whole contents (except the communication), the front being removed.

206. Fig. 3. Side view of the same, the side of the case, and drawers being removed.

207. Fig. 4. One of the drawers, with the spring supports, or props for the plates.

208. Fig. 5. Front view of the communications.

209. Fig. 6. Side view of ditto.

210. The Voltaic series consists of sixty pairs of plates, four inches square, each plate presenting its whole surface to the action of the acid; they are arranged in two drawers A, A, one above the other, each drawer containing three porcelain troughs *a*, *a*, *a*, and each trough ten pair of plates *b*, *b*, *b*; the plates are suspended from rods *c*, *c*, *c*, connecting each set of ten pairs together, and these rods drop into a square frame *d*, *d*, made to the full size of each drawer inside: the action of these frames lowers or raises the whole of the plates together, and is thus contrived.

211. B, B, are two rods passing through the upper board or table, and resting upon the short arm of the levers C, C, fig. 2, which are of wood; these rods have each two pairs of pins *e*, *f*; and which in fig. 2 are represented as employed, the plates being in action; but in fig. 3 the contrary, the lower drawer being open, and the frames, with plates supported by their props D, D. The drawers being first shut, the handles E, E, of the rod B, are to be turned inwards, as in fig. 2, when the pins *e*, *e*, enter the openings cut in the sides of the drawers at *g*, fig. 4, and stop in the grooves *h*, *h*, fig. 2, cut in the square frame *d*, to receive them; in the mean while, the shorter pins *f*, *f*, bearing upon the lower sides of the spring props D, press their upper end or points entirely within the thickness of the drawer on each side, and release the frames *d*, *d*. The whole weight of the plates, now bearing only upon the rods, is counterpoised by the weight *w*, which connects the two levers C, C; they are gradually let down into their several partitions, and the action of the battery commences; at the conclusion of the experiment the rods are again raised by the handles E, E, and when stopped, the pins *e*, having reached the top of the groove *g*, fig. 4, the handles are to be turned back into their former position, as in fig. 3; the props D, being now first released, shoot into the drawers, and support the frames when the pins *e*, *e*, have quitted them.

212. The communications between each trough are effected in the usual manner; but those which conduct the fluid from one drawer to the other, and from the opposite ends of the series to the upper board or table, are capable of being disengaged, and their connexions are effected under mercury, as in the Voltaic discharger.

213. They are thus arranged: *i*, *i*, *i*, are ivory cups containing mercury, and fixed to the drawers; *j*, *j*, *j*, are platina wires depending from them, and entering the troughs; *k* is a ring and wire, which effects the communication between the two drawers; and *l*, *l*, are the two wires which conduct the fluid from the opposite ends of the battery to the table, C being the copper, and Z the zinc end of the series.

214. We have stated that when the opposite extremities of a powerful Voltaic apparatus are connected by a wire, at the moment of contact a distinct spark is perceived, which occurs every time the contact is alternately broken and renewed. If the contact is made with a wire terminated at the end by a piece of well-burnt charcoal, the spark is considerably more vivid. And if two wires proceeding from the opposite ends of the battery are armed with charcoal points, and brought in contact with each other, the light evolved is more brilliant and intense than any that has been procured by other artificial arrangements. When the battery is powerful, the emission of light may be kept up for a considerable time; it is so dazzling as to fatigue the eye even by a temporary glance, and, when it ceases, leaves the most brilliantly illuminated room in apparent darkness.

215. This light appears to be principally derived from the immediate action of the Voltaic apparatus, and not from the combustion of the charcoal; for, though that is partly ignited, it suffers but comparatively little waste, and the light is evolved with equal splendor when the experiment is made in gases which contain no oxygen; and will even take place, though with diminished energy, under water, alcohol, ether oils, and other fluids whose conducting power is not too great.

216. The influence of the Voltaic spark on various gases may be ascertained by the apparatus represented at fig. 1, plate II., Electro-Galvanism, the wires within the globe being ter-

minated by pointed pieces of charcoal, instead of balls. When a globe of this kind has been exhausted and filled with sulphureted hydrogen, on taking the Voltaic spark in it, the sulphur is separated, and deposited on the interior of the globe, and produces, during its separation, a very beautiful appearance.

217. Some other compound gases are similarly affected; phosphorus separates from phosphureted hydrogen, and arsenic from arsenureted hydrogen.

218. With the most powerful Voltaic batteries the striking distance of the spark, or interval at which it passes from one conductor to another, is very considerable. Mr. Children measured this effect by means of a micrometer, attached to two polished points of platina, which were inserted in a receiver containing very dry air. With 1250 pairs of plates the points were brought within one-fifteenth of an inch of each other before the spark took place. With a large apparatus employed at the London Institution, which extends to 2000 pairs of four-inch plates, points of charcoal were brought within a thirtieth or fortieth of an inch of each other before any light was evolved; but, when the points of charcoal had become intensely ignited, a stream of light continued to play between them when they were gradually withdrawn even to the distance of nearly four inches. The stream of light was in the form of an arch, broad in the middle and tapering towards the charcoal points; it was accompanied by intense heat, and immediately ignited any substance introduced into it; fragments of diamond, and points of plumbago disappeared, and seemed to evaporate, even when the experiment was made in an exhausted receiver; though they did not appear to have been fused. Thick platina wire melted rapidly, and fell in large globules; the sapphire, quartz, magnesia, and lime, were distinctly fused.

219 In rarefied air, the discharge took place at a greater distance, and the beam of light was made to pass through an interval of six or seven inches.

220. These phenomena may be exhibited on a smaller scale by means of 100 pairs of plates, of six inches square, an apparatus which is well suited for all experiments of fusion and ignition.

221. The arched form of the stream of light, passing between two charcoal points, is often very perceptible when the distance of the points does not exceed half an inch.

222. From the low intensity of the most powerful Voltaic apparatus, but little attention to insulation is required in the transmission of its effects. The conductors employed for this purpose consist of copper wires passed through a short piece of glass tube, which serves as an insulator to hold them by. Such conductors are represented attached to the battery, and placed on a glass plate to inflame gunpowder, at fig. 2.

223. As the charcoal points usually become ignited when the battery has moderate power, almost any combustible substance may be inflamed, if placed between them. Oils, alcohol, ether, and naphtha, are decomposed when the points are plunged into them, and inflamed when they are brought near each other upon the surface.

224. Some of the most pleasing effects of the Voltaic apparatus result from its action on metals; if these substances, in thin leaves, are made the medium of communication between the opposite ends of a powerful battery, they inflame, and by continuing the contact may be made to burn with great brilliance. The best method of performing these experiments, is to suspend the metallic leaves to a bent wire proceeding from one extremity of the battery, and to bring in contact with them a broad metal plate connected with the opposite extremity; the brilliancy of the effect may be increased by covering the plate with gilt foil. Gold leaf burns with a vivid white light tinged with blue, and produces a dark brown oxide. Silver leaf emits a brilliant emerald-green light, and leaves an oxide of a dark gray color. Copper produces a bluish-white light attended by red sparks; its oxide is dark brown. Tin exhibits nearly similar phenomena; its oxide is of a lighter color. Lead burns with a beautiful purple light; and zinc with a brilliant white light, inclining to blue, and fringed with red. For the distinct appearance of these colors it is essential to make the contacts with the metal; for, if charcoal be used, the brilliant white light it evolves absorbs the colors produced by the combustion of the metals.

225. If a fine iron wire be connected with one extremity of a powerful battery, and its end be brought to touch the surface of some quicksilver connected with the other extremity, a vivid combustion both of the wire and the quicksilver results, and a very brilliant effect is produced.

226. If a fine iron wire of moderate length be made the medium of connexion between the extremities of the battery, it becomes ignited, and may be fused into balls; or if a platina wire is employed, it may be kept at a red, or even white, heat, for a considerable length of time; which seems to prove that some power is continually circulating through it; but however powerful the battery, wires are never dispersed by it, as they are by the action of a charged surface.

227. If the slender wire be inserted in any fluid, and then introduced into the Voltaic circuit, the fluid may be made to boil.

228. It has been noticed, that, if any two wires of different thicknesses are taken, on either of which a certain battery can produce ignition, a greater length of the thickest wire will be ignited than of that which is thinner. This effect may probably arise from the cooling influence of the air, for the surface of the thin wire is most extensive in proportion to its quantity of metal; and that the surrounding medium has an influence on the degree of ignition may be proved by another experiment.

229. Stretch a fine wire of platina, withinside a glass receiver, placed upon an air-pump, so that the air surrounding the wire may be removed or restored at pleasure. Ignite the wire to a dull red heat, by connecting its opposite extremities with the wires from a Voltaic battery, of sufficient power for that purpose

Rarefy the air by the action of the pump; and as the rarefaction proceeds, the ignition of the wire will become more vivid, until at length it obtains a glowing white heat. Admit air into the receiver, and the wire will lose its intense heat, and appear more dull than at first. Rarefy the air again, the ignition will increase. Restore it to its original density, it will again diminish. These effects may be repeated many times, and will maintain the same proportion to each other, though they are less intense at each repetition.

230. The power of a Voltaic apparatus increases with the number of plates it contains, within certain limits, but the limit is different for the various effects it produces, and varies also with the manner of employing the apparatus.

231. The effects have been stated by Volta to be in the simple ratio of the numbers, but very limited series only had been put together at the time this statement was made, and there appears to be a loss of power when very extensive arrangements are employed. The pure electrical effects, and the force of the shock, are found to increase with the number, and an arrangement of 1500 may be employed. The power of chemical decomposition, and transfer, also continues to increase with the number when the battery is excited by dilute acid; but, if it be charged with river water, the power does not increase after 400 or 500 plates. The powers of ignition have increased in exact proportion to the numbers within the limit of 100 plates, beyond that limit there appears to be a loss of power; for Sir H. Davy found that 100 plates ignited three inches of platina wire, one-seventieth of an inch diameter, and 1000 similar plates, charged in the same way, ignited only thirteen inches.

232. The French chemists have investigated the ratio of increase for different numbers of plates, as indicated by the quantity of gas liberated by the decomposition of water; and they announce that the increase is as the cube root of the number of plates. The apparatus they employed, was arranged in the form of troughs of a particular construction, being part of a large apparatus constructed by order of the French government. Sir H. Davy states, that he has made similar experiments with the large combination of porcelain troughs, employed in the Royal Institution, and the results he obtained indicate an increase nearly as the squares of the numbers.

233. The result of every experiment of the kind must be uncertain if a series of minute attentions are not observed, which appear to have been overlooked in those already instituted. The vessels employed for the decomposition should be of the same size and form; the wires of the same length and thickness, and placed at equal distances from each other, in a fluid of uniform conducting power.

234. When the size of the plates is increased, their effects on perfect conductors, such as metals, charcoal, and strong acid solutions, are greatly augmented; but their action on imperfect conductors, as water, and various weak saline solutions, remains unaltered. If a battery, for instance, of thirty pairs of plates of two inches square, be compared with another battery of thirty plates, of six inches square, charged with diluted acid of the same strength; there will be no material difference in the shock they produce, or the quantity of water they decompose in a given time; but the small battery will not melt wire, or burn metals, and will scarcely produce a spark between two points of charcoal; whilst the large battery will evolve a brilliant light between the charcoal points, deflagrate metallic leaves with rapidity, and ignite several inches of wire.

235. This remarkable fact, which appears to have been first noticed by the French chemists, is susceptible of some explanation (on the supposition that the phenomena are electrical). If a Leyden jar, for instance, having a square foot of coated surface, be applied to an electrical machine with another jar, whose coated surface is equal to four square feet; after a certain number of turns of the machine, they will both be charged, and to the same intensity, for they will equally affect an electrometer. But the large jar will contain four times the quantity of electricity that the small one does, and will fuse sixteen times the quantity of wire.

236. Now, suppose an imperfect conductor, capable of transmitting only such a quantity of electricity as is adequate to the charge of half a square foot; and it is obvious either of the jars before mentioned would produce the same effect on such a substance; for they both contain more than it can transmit, and its conducting power, which remains the same in both cases, limits the effect that can be produced by either. It is consequently found, that, if several different sized jars are charged to the same degree, the shock is nearly equally painful when received from either of them.

237. Mr. Cavendish has stated, that 'iron wire conducts 400,000,000 times better than rain or distilled water; that is, the electricity meets with no more resistance in passing through a piece of iron wire 400,000,000 inches long, than through a column of water of the same diameter only one inch long. Sea water, or a solution of one part of salt in thirty of water, conducts 100 times, and a saturated solution of sea salt about 720 times better than rain water.' It is therefore probable, that the power excited by a Voltaic apparatus, with plates of two inches square, is in quantity equal or superior to the conducting capacity of most aqueous fluids, and consequently no increased effect can be produced on such fluids by larger plates, which increase the quantity of that power, but not its intensity. But if a conductor be presented to the large plates, which is capable of receiving the increased quantity furnished, the effect must necessarily be greater on such conductors, in proportion to the increased impulse it may be supposed to receive. These facts are capable of easy illustration.

238. Let two wires, proceeding from the extremities of a battery of fifty or 100 plates of two inches square, be plunged in separate glasses of water, if the glasses are connected by putting a finger into each of them, a shock will be felt at the moment of contact. Connect the water

in the glasses by some fibres of moistened cotton, or by an inverted syphon filled with water; on repeating the contact with this arrangement, either no shock, or a very slight one will be felt. Make a similar experiment with another battery of the same extent, but with plates of six inches square. The shock will be nearly as great when the glasses are connected by moistened fibres, as when no connexion exists between them; and whilst the circuit exists through the moistened fibres, and the human body, if a third circuit be formed through a fine wire, several inches of it may be ignited. The imperfect conductors being incapable of conducting more than a small portion of the power excited by the large plates.

239. Whatever be the cause of the power of the Voltaic apparatus, the quantity of that power excited by any given number of plates under similar circumstances, will be in direct proportion to the size of the plates; and if the power be electricity, or should obey the same law that operates with charged surfaces, the comparative action of different sized batteries, containing the same number of plates, should be, with regard to their power of igniting wire, in the proportion of the square of the increased surface; thus if two batteries are taken, one containing fifty plates of twenty square inches surface, and the other fifty plates of forty square inches, the latter ought to ignite four times the length of wire the former can ignite. From some experiments with plates of four inches square, and others with plates of eight inches square, made many years since, it has been stated by Dr. Wilkinson, 'that the power of ignition, in batteries of the same total surface, but with plates of different sizes, increases in the proportion of the squares of the surfaces of the elementary plates, singly taken in each.' It was afterwards shown by Mr. Harrison of Kendal, that when the total surfaces are not equal, the rate of ignition must be as the sixth power of the diameters of the elementary plates, or as the cubes of their respective surfaces.

240. It appears also from some experiments with large plates, mentioned by Sir H. Davy, that the power of ignition, for equal number of plates, probably increases in a higher proportion than the squares of their surfaces; for twenty double plates, each exposing a surface of eight square feet, ignited more than sixteen times as much wire as twenty double plates, having each a surface of two square feet.

241. Several curious galvanic experiments and observations have been published by M. Bichat, author of a very celebrated work on anatomy. In speaking of the influence of the destruction of the brain on that of the heart, after having proved, conformably to observation and experience, that it is not immediately by the interruption of the cerebral action that the heart ceases to act, he confirms this fundamental datum of physiology and pathology, by a series of galvanic experiments, which demonstrate that the heart is in all cases independent of the brain.

242. 'These experiments,' he observes, 'were made by me with the most scrupulous attention, because several very respectable authors have recently advanced an opinion contrary to mine and have endeavoured to prove that the heart, together with the other muscles of organic life, do not differ, as to their susceptibility to the galvanic influence, from the different muscles of animal life. I shall begin by a detail of the observations I have made on animals with red and cold blood.

243. (1.) 'In several experiments made on frogs, I coated the brain, on the one hand with lead, and the heart and muscles of the inferior extremities, on the other, with a long lamina of zinc, the upper end of which touched the heart, and the lower end the muscles. Having, by the means of silver, established a communication between the coatings of the muscles and those of the brain, the movements of the limbs constantly followed; but I could not perceive any acceleration in the contractions of the heart, when it still continued to beat; and, when its action had entirely ceased, it did not display the smallest movement. Whichever may be the voluntary muscle that is coated at the same time with the heart, with a view to a comparison of the phenomena they exhibit at the moment of the metallic communication, there is constantly a marked and decided difference.

244. (2.) 'In the case of other frogs, I coated, with a common metallic wire, on the one hand, the cervical part of the spinal marrow, in the upper region of the heart, to the end that the coating might be above the part where the nerves which proceed from the great intercostal nerve, and thence to the heart, originate; and, on the other hand, the heart, and any one of the voluntary muscles. I constantly noticed a result similar to the one which attended the preceding experiment, whenever the communication was established. There were invariably violent agitations in the voluntary muscles, without any visible alteration in the contractile movements of the heart.

245. (3.) 'I endeavoured to denudate the nerves which lead to the heart of frogs. Several grayish filaments, scarcely perceptible, with the nature of which I must acknowledge I am not positively acquainted, were coated with a metallic substance, at the same time that the heart was made to rest on a substance of a similar nature. When the communication was established by the means of a third metal, not the smallest sensible effect was to be perceived.'

246 Dr. Wilson Philip has made some curious experiments on the influence of the Voltaic battery in obviating the effects of the division of the eight pairs of nerves. In some experiments in which the nerves of the eighth pair were divided in the neck of a rabbit, and the ends not displaced, and the animal was allowed to live some hours, it was found that food swallowed immediately before the division of the nerves, was considerably digested, even when the divided ends of the nerves had separated to the distance of a quarter of an inch from each other.

247. In other experiments in which, after the division of the nerves, the divided ends had been turned completely away from each other, little or no perfectly digested food, when the animal

was allowed to live some hours, was found in the stomach: and the longer the animal lived, the smaller was the proportion of digested food in the stomach, the great mass having the appearance of masticated food, which was not sensibly lessened in quantity, however long the animal lived. In an experiment in which, under some circumstances, the stomach was exposed, from the time of the division of the nerves, to the influence of a Voltaic battery sent through the lower portion of the divided nerves, its contents were apparently as much changed as they would have been in the same time in the healthy animal. The change was also of the same kind, the contents of the stomach assuming a dark color, and those of the pyloric end being more uniform, and of a firmer consistence than those of the central and cardiac portions of the stomach, while the whole contents became less in quantity.

248. The division of the nerves, in both ways, produced difficulty of breathing and efforts to vomit; neither of which occurred, when the stomach and lungs were brought under the influence of a Voltaic battery, sent through the lower portion of the divided nerves.

249. When, under the foregoing circumstances, the lungs had not been exposed to the Voltaic influence, and the animal had been allowed to live for five or six hours, they were found much affected: in the rabbit which had been submitted to this influence, they seemed quite healthy.

250. An account of some very interesting experiments performed by Dr. Ure, on the body of a criminal executed in the north, was read before the Glasgow Literary Society. The paper commences with some appropriate general physiological views relating to the application of galvanism, in which the author notices particularly the researches of Dr. Wilson Philip on the relation between Voltaic electricity and the phenomena of life. The author gives the following detail of his experiments.

251. 'The subject of these experiments was a middle-sized, athletic, and extremely muscular man, about thirty years of age. He was suspended from the gallows nearly an hour, and made no convulsive struggle after he dropped; while a thief executed along with him, was violently agitated for a considerable time. He was brought to the anatomical theatre of the University of Glasgow in about ten minutes after he was cut down. His face had a perfectly natural aspect, being neither livid nor tumefied; and there was no dislocation of his neck.

252. 'Dr. Jeffrey, the distinguished professor of anatomy, having on the preceding day requested me to perform the galvanic experiments, I sent to his theatre with this view, next morning, my minor Voltaic battery, consisting of 270 pairs of four-inch plates, with wires of communication, and pointed metallic rods with insulating handles, for the more commodious application of the electric power. About five minutes before the police officers arrived with the body, the battery was charged with a dilute nitro-sulphuric acid, which speedily brought it into a state of intense action. The dissections were skilfully executed by Mr. Marshall, under the superintendence of the professor.

253. 'Experiment I.—A large incision was made into the nape of the neck, close below the occiput. The posterior half of the atlas vertebra was then removed by bone forceps, when the spinal marrow was brought into view. A considerable incision was at the same time made in the left hip, through the great gluteal muscle, so as to bring the sciatic nerve into sight; and a small cut was made in the heel. From neither of these did any blood flow. The pointed rod connected with one end of the battery was now placed in contact with the spinal marrow, while the other rod was applied to the sciatic nerve. Every muscle of the body was immediately agitated with convulsive movements, resembling a violent shuddering from cold. The left side was most powerfully convulsed at each renewal of the electric current. On moving the second rod from the hip to the heel, the knee being previously bent, the leg was thrown out with such violence as nearly to overturn one of the assistants, who in vain attempted to prevent its extension.

254. 'Experiment II.—The left phrenic nerve was now laid bare at the outer edge of the sterno-thyroideus muscle, from three to four inches above the clavicle; the cutaneous incision having been made by the side of the sterno cleido-mastoideus. Since this nerve is distributed to the diaphragm, and since it communicates with the heart through the eighth pair, it was expected by transmitting the galvanic power along it, that the respiratory process would be renewed. Accordingly, a small incision having been made under the cartilage of the seventh rib, the point of the one insulating rod was brought into contact with the great head of the diaphragm, while the other point was applied to the phrenic nerve in the neck. This muscle, the main agent of respiration, was instantly contracted, but with less force than was expected. Satisfied, from ample experience on the living body, that more powerful effects can be produced in galvanic excitation, by leaving the extreme communicating rods in close contact with the parts to be operated on, while the electric chain or circuit is completed, by running the end of the wires along the top of the plates in the last trough of either pole, the other wire being steadily immersed in the last cell of the opposite pole, I had immediate recourse to this method. The success of it was truly wonderful. Full, nay laborious breathing instantly commenced. The chest heaved, and fell; the belly was protruded, and again collapsed, with the relaxing and retiring diaphragm. This process was continued, without interruption, as long as I continued the electric discharges.

255. 'In the judgment of many scientific gentlemen who witnessed the scene, this respiratory experiment was perhaps the most striking ever made with a philosophical apparatus. Let it also be remembered, that, for full half an hour before this period, the body had been well nigh drained of its blood, and the spinal marrow severely lacerated. No pulsation could be perceived meanwhile at the heart or wrist; but it may be supposed that, but for the evacuation of the blood, the essential stimulus of that organ, this phenomenon might also have occurred.

256. 'Experiment III.—The supra-orbital nerve

was laid bare in the forehead, as it issues through the supra-ciliary foramen, in the eye-brow: the one conducting rod being applied to it, and the other to the heel, most extraordinary grimaces were exhibited every time that the electric discharges were made, by running the wire in my hand along the edges of the last trough, from the 220th to the 227th pair of plates; thus fifty shocks, each greater than the preceding one, were given in two seconds: every muscle in his countenance was simultaneously thrown into a fearful action; rage, horror, despair, anguish, and ghastly smiles, united their hideous expression in the murderer's face, surpassing far the wildest representations of a Fuseli or a Kean. At this period several of the spectators were forced to leave the apartment from terror or sickness, and one gentleman fainted.

257. 'Experiment IV.—The last galvanic experiment consisted in transmitting the electric power from the spinal marrow to the ulnar nerve, as it passes by the internal condyle at the elbow; the fingers now moved nimbly, like those of a violin performer; an assistant, who tried to close the fist, found the hand to open forcibly, in spite of his efforts. When the one rod was applied to a slight incision at the tip of the fore-finger, the fist being previously clenched, that finger extended instantly; and, from the convulsive agitation of the arm, he seemed to point to the different spectators, some of whom thought he had come to life!'

258. An hour was spent in these experiments, when an experiment was made with the view of determining the quantity of residual air in the lungs; after the detail of which, the author proceeds as follows.

259. 'In deliberating on the above galvanic phenomena, we are almost willing to imagine, that if, without cutting into and wounding the spinal marrow and blood-vessels in the neck, the pulmonary organs had been set a-playing at first (as I proposed), by electrifying the phrenic nerve (which may be done without any dangerous incision), there is a probability that life might have been restored. This event, however little desirable with a murderer, and perhaps contrary to law, would yet have been pardonable in one instance, as it would have been highly honorable and useful to science. From the accurate experiments of Dr. Philip, it appears that the action of the diaphragm and lungs is indispensable towards restoring the suspended action of the heart and great vessels, subservient to the circulation of the blood.

260. 'It is known that cases of death-like lethargy, or suspended animation from disease and accidents have occurred, where life has returned, after longer interruption of its functions than in the subject of the preceding experiments. It is probable, when apparent death supervenes from suffocation with noxious gases, &c., and when there is no organic defect, that a judiciously directed galvanic experiment will, if any thing will, restore the activity of the vital functions. The plans of administering Voltaic electricity hitherto pursued in such case, are, in my humble apprehension, very defective. No advantage, we perceive, is likely to accrue from passing electric discharges across the breast, directly through the heart and lungs. On the principles so well developed by Dr. Philip, and now illustrated on Clydsdale's body, we should transmit along the channel of the nerves, that substitute for nervous influence, or that power which may perchance awaken its dormant faculties. Then, indeed, fair hopes may be formed of deriving extensive benefit from galvanism; and of raising this wonderful agent to its expected rank, among the ministers of health and life to man.

261. 'I would, however, beg leave to suggest another nervous channel, which I conceive to be a still readier and more powerful one to the action of the heart and lungs than the phrenic nerve. If a longitudinal incision be made, as is frequently done for aneurism, through the integuments of the neck at the outer edge of the sterno-mastoideus muscle, about half way between the clavicle and angle of the lower jaw; then, on turning over the edge of this muscle, we bring into view the throbbing carotid, on the outside of which the par vagum and great sympathetic nerve lie together in one sheath. Here, therefore, they may both be directly touched and pressed by a blunt metallic conductor. These nerves communicate directly or indirectly with the phrenic, and the superficial nerve of the heart is sent off from the sympathetic.

262. 'Should, however, the phrenic nerve be taken, that of the left side is the preferable of the two. From the position of the heart, the left phrenic differs a little in its course from the right. It passes over the pericardium, covering the apex of the heart.

263. 'While the point of one metallic conductor is applied to the nervous cords above described, the other knob ought to be firmly pressed against the side of the person, immediately under the cartilage of the seventh rib. The skin should be moistened with a solution of common salt, or, what is better, a hot saturated solution of sal ammoniac, by which means the electric energy will be more effectually conveyed through the cuticle, so as to complete the Voltaic chain.

264. 'To lay bare the nerves above described, requires, as I have stated, no formidable incision, nor does it demand more anatomical skill, or surgical dexterity, than every practitioner of the healing art ought to possess. We should always bear in mind that the subject of experiment is at least insensible to pain; and that life is at a stake, perhaps irrecoverably gone. And assuredly, if we place the risk and difficulty of the operations in competition with the blessings and glory consequent on success, they will weigh as nothing with the intelligent and humane.' It is possible, indeed, that two small brass knobs, covered with cloth moistened with solution of sal ammoniac, pressed above and below on the place of the nerve and the diaphragmatic region, may suffice, without any surgical operation. It may first be tried.

265. 'Immersion of the body in cold water accelerates greatly the extinction of life arising from suffocation; and hence less hopes need be entertained of recovering drowned persons after a considerable interval, than when the vital heat has been suffered to continue with little abate-

ment. None of the ordinary practices judiciously enjoined by the Humane Society, should ever, on such occasions, be neglected. For it is surely criminal to spare any pains which may contribute, in the slightest degree, to recall the fleeting breath of man to its cherished mansion.'

266. We have hitherto confined ourselves to the effects of small batteries, but we must not omit to notice the powerful Voltaic apparatus constructed by Mr. Children, as well as the results obtained by it, or the more portable as well as powerful arrangement by Mr. Pepys. In the first of these arrangements, the copper and zinc plates of the apparatus were connected together, in the usual order, by leaden straps, six feet long by two feet eight inches broad, each plate presenting thirty-two square feet of surface. All the plates being attached to a strong wooden frame suspended by ropes and pulleys, which, being balanced by counterpoises, was easily lowered and elevated, so as to immerse the plates in the acid, or raise them out of it at pleasure. The cells of the battery were twenty-one in number, and their united capacities amounted to 945 gallons. To each pole of the battery a leaden pipe, about three-fourths of an inch in diameter, was attached by solder, and the opposite end of each pipe immersed in a basin of mercury (a separate basin for each pipe), by means of which the circuit was completed, and a perfect contact ensured. The battery was afterwards improved at the suggestion of Dr. Wollaston, and the copper coiled completely round each zinc surface. See fig. 3, plate II. The first experiments we shall mention were made on the comparative facility with which different metals are ignited when placed in the electrical circuit. For this purpose, in each experiment, two wires of dissimilar metals were taken, of equal diameter and length; one end of each was in contact with one of the basins of mercury communicating with the poles of the battery, and the other end bent to an angle, and the wires connected continuously by hooking them together. The length of each wire was eight inches, and the diameter one-thirtieth of an inch. The battery was moderately excited by a charge of one part acid diluted with forty parts of water.

267. Experiment I.—A platina and a gold wire being thus connected, and introduced into the electrical circuit, the platina was instantly ignited, the gold remained unaffected.

268. Experiment II.—A similar arrangement of gold and silver wires. The gold was ignited, the silver not.

269 Experiment III.—The same with gold and copper. No perceptible difference in the state of ignition; both metals were heated red.

270. Experiment IV.—Gold and iron. The iron was ignited; the gold unchanged.

271. Experiment V.—Platina and iron. The iron ignited instantly at the point of contact next the pole of the battery. Then the platina became ignited through its whole extent. After this the iron became more intensely heated than the platina, and the ignition of the latter decreased.

272. Experiment VI.—Platina and zinc. The platina was ignited: the zinc was not; but melted at the point of contact. In a subsequent experiment, the zinc did not melt; but the platina ignited as before.

273. Experiment VII.—Zinc and iron. The iron was ignited: the zinc bore the heat without fusing.

274. Experiment VIII.—Lead and platina. The lead fused at the point of contact.

275. Experiment IX.—Tin and platina. The tin fused at the point of contact. No ignition of either wire took place in the two last experiments.

276. Experiment X.—Zinc and silver. The zinc was ignited before it melted: the silver was not ignited.

277. The results in every case were the same to whichever pole of the battery either wire was presented. These experiments were varied by introducing several alternations of different wires continuously connected, into the circuit, and obtained in every instance analogous results. Thus,

278. Experiment XI.—Alternations of platina and silver, three times repeated: all the platina wires were ignited, and none of the silver.

279. Experiment XII.—One zinc wire between two platina: both the platina wires were ignited, the zinc not.

280. Experiment XIII.—One iron between two platina. Both the latter first ignited; then the iron, which soon became fully heated, and fused.

281. It is unnecessary to enter into a farther detail of these experiments; it will be sufficient to say generally, that when wires of several different metals were introduced at once into the circuit, the order of their ignition was precisely that of the former experiments. In one experiment the copper was decidedly most heated.

282. To explain these phenomena, Mr. Children supposes that when a perfect communication is established between the poles of the battery, the electricity circulates without producing any visible effect; but, if it meet with resistance in its passage, it manifests itself by chemical action, by the evolution of heat, or both. Thus, if a bar of metal be connected with one pole of the battery, and its extremity immersed in a basin of mercury connected with the other pole, at the instant the surfaces come in contact, heat and light are evolved, which cease as soon as the bar, if it be of sufficient size, is fairly plunged beneath the surface of the quicksilver. If the circuit be completed by two pieces of charcoal, the evolution of heat and light is permanent, as long as their surfaces remain in contact, because that contact can never be so perfect, as to oppose no resistance to the electricity; whereas, in the case of the bar of metal and the mercury, it soon becomes complete, and the current is then uninterrupted. Resistance, therefore, appears to occasion the development of heat (whatever be the ultimate cause of the phenomenon), and as this must be inversely as the conducting power, when any two of the wires connected continuously are placed in the circuit, that which is the worst conductor must be most heated; and thus platina, having the lowest conducting power, is ignited before all

the rest; and silver, which conducts best, is not heated red when connected with any of the other metals.

283. The following experiments were made with the battery in a high state of excitation; and Mr. Children considers them as representing nearly the maximum of effect which it is capable of producing. As the quantity of acid was increased from time to time, and that previously added often almost spent before fresh was put in, it is not easy to say exactly what proportion it bore to the water; perhaps the largest may be stated at about $\frac{1}{30}$th. On this, as on former occasions, he found a mixture of nitrous and sulphuric acids, to produce the most powerful and permanent effects.

284. Experiment I.—Five feet six inches of platina wire, $\frac{11}{100}$ of an inch in diameter, were heated red throughout, visible in full daylight.

285. Experiment II.—Eight feet six inches of platina wire, $\frac{11}{100}$ of an inch in diameter, were heated red.

286. Experiment III.—A bar of platina $\frac{1}{6}$ of an inch square, and $2\frac{1}{4}$ inches long, was also heated red, and fused at the end; and,

287. Experiment IV.—A round bar of the same metal, $\frac{275}{1000}$ of an inch in diameter, and $2\frac{1}{4}$ inches long, was heated bright red throughout.

288. Experiment V.—Fine points of boxwood charcoal intensely ignited in chlorine, neither suffered any change, nor produced any in the gas. The result was similar when heated in azote.

289. Mr. C. next tried the power of the battery to fuse several refractory substances. The subject of experiment was placed in a small cavity, made in a piece of well burnt boxwood charcoal, floating on the surface of the mercury in one of the basins before mentioned, and the circuit completed by another piece of charcoal, communicating by stout copper wire with the other basin.

290. Experiment I.—Oxide of tungsten, which (as well as other metallic oxides operated on) had been previously intensely ignited in a charcoal crucible, in a powerful furnace, fused, and was partially reduced. The metal grayish white, heavy, brilliant, and very brittle.

291. Experiment II.—Oxide of tantalum. A very small portion fused. The grains have a reddish-yellow color, and extremely brittle.

292. Experiment III.—Oxide of uranium; fused, but not reduced.

293. Experiment IV.—Oxide of titanium; fused, not reduced. When intensely heated, it burnt, throwing off brilliant sparks like iron.

294. Experiment V.—Oxide of cerium; fused, and when intensely heated it burnt with a large, vivid white flame, and was partly volatilised, but not reduced. The fused oxide, on exposure for a few hours to the air, fell into a light brown powder, containing numerous shining particles of a silvery lustre interspersed amongst it, and exhaled an odor, similar to that of phosphureted hydrogen.

295. Experiment VI.—Oxide of molybdena; readily fused and reduced. The metal is very brittle, of a steel gray color, and soon becomes covered with a thin coat of purple oxide.

296. Experiment VII.—Compound ore of iridium and osmium; fused into a globule.

297. Experiment VIII.—Pure iridium; fused into an imperfect globule, not quite free from small cavities, and weighing 7·1 grains. The metal is white, very brilliant, and in its present state its specific gravity is 18·68, which must be much too low, on account of the porous state of the globule. In the Minutes of the Experiments, in July 1813, mention is made of the fusion of a small portion of pure iridium into a globule weighing $\frac{93}{100}$ of a grain, which had been previously submitted to the action of a battery of 2000 plates, of four inches square, without melting.

298. Experiment IX.—Ruby and sapphire, were not fused.

299. Experiment X.—Blue spinal ran into a slag.

300. Experiment XI.—Gadolinite, fused into globules.

301. Experiment XII.—Magnesia was agglutinated.

302. Experiment XIII.—Zircon from Norway was imperfectly fused.

303. Experiment XIV.—Quartz, silex, and plumbago, were not affected.

304. In the year 1796 M. Clouet converted iron into steel, by cementation with the diamond, with the view of confirming the nature of that substance, and of ascertaining the exact state in which carbon exists in steel. Clouet had also previously formed steel by cementation with carbonate of lime. Mr. Mushet repeated this experiment, using, instead of the carbonate, caustic lime, and obtained also what he considered to be cast steel; whence he concluded that the carbon necessary to convert the iron into steel had not been furnished, as Clout supposed, by decomposition of the carbonic acid, but that it had found its way from the ignited gas of the furnace to the iron. This result occasioned suspicions of the accuracy of the deductions from the experiment with the diamond; and Mr. Mushet accordingly, at the suggestion of the editor of the Philosophical Magazine, repeated the experiment made at the Polytechnic School, only keeping out the diamond. The results (for he made several experiments), uniformly gave him good cast steel, whence he concludes that we are still without any satisfactory or conclusive proof of the steelification of iron solely by means of the diamond; and adds that he doubts whether the diamond afforded even one particle of carbon to the iron. The details of both Clouet's and Mushet's experiments, may be found in the fifth volume of the Philosophical Magazine. Sir George M'Kenzie repeated both results confirming the conclusions of the French chemist. The labors of this gentleman would at first view appear conclusive; but, if a doubt should remain, it occurred to Mr. Pepys, that the battery would afford an experimentum crusis on the subject; and his ingenuity readily suggested a mode of making it, every way unobjectionable. He bent a wire of pure soft iron, so as to form an angle in the middle, in which part he divided it longitudinally, by a fine saw. In the opening, so formed, he placed diamond powder, securing it in its situa-

tion by two finer wires, laid above and below it, and kept from shifting, by another small wire, bound firmly and closely round them. All the wires were of pure soft iron, and the part containing the diamond powder was enveloped by thin leaves of talc. Thus arranged, the apparatus was placed in the electrical circuit, when it soon became red hot, and was kept so for six minutes. The ignition was so far from intense, that few who witnessed the experiment expected any decisive result. On opening the wire, however, Mr. Pepys found that the whole of the diamond had disappeared; the interior surface of the iron had fused into numerous cavities, notwithstanding the very moderate heat to which it had been exposed; and all that part which had been in contact with the diamond was converted into perfect blistered steel. A portion of it being heated red, and plunged into water, became so hard as to resist the file, and to scratch glass. This result is conclusive; for as the contact of any carbonaceous substance, except the included diamond, was effectually guarded, to that alone can the change produced in the iron be referred. This experiment will also probably be deemed fatal to the opinion of those mineralogists (if any do still maintain that opinion), who class the diamond with substances of the siliceous genus.

305. When dry caustic potassa was exposed to the intense heat between the two pieces of charcoal, it fused, and appeared to decompose, throwing off a large flame of the peculiar purple color, that attends the combustion of potassium. When moist caustic potassa was placed in the circuit, the water only was decomposed.

307. The second apparatus was constructed under the immediate direction of Mr. Pepys for the London Institution, and the great portability of this gigantic galvanic spiral gives it an especial claim to the notice of the scientific world. The apparatus is shown at fig. 4.

308. The two tubs, T, T, are somewhat larger than the metallic coil. The one beneath the weight is intended as a receptacle for water, while the other is charged with dilute acid.

309. The spiral M is suspended by a cord, and balanced by the weight W; the beam over which the cord passes being moveable on a central axis at the top of the upright piece of timber.

310. The coil consists of two plates, each fifty feet in length and two feet in width; the one copper, and the other zinc, making a superficial surface of 400 feet. They are rolled or wrapped round a cylinder of wood, with three strands or ropes of horse-hair between each plate, to prevent contact of the metals; and, to maintain these in their situation, notched sticks are occasionally introduced in the rolling. Two conductors of copper, near three-fourths of an inch in thickness, are firmly attached to the end of each plate, from which the power is dispensed upon immersion in the acid.

311. Rather more than fifty gallons of dilute acid are requisite to charge the receptacle intended for the metallic spiral; and, to put the apparatus in operation, the coil is gradually lowered into the tub beneath. The immersion of the spiral, however, displaces a certain portion of water; so that it is necessary to restore the equilibrium by withdrawing one of the balance-weights. In the apparatus actually employed in the theatre of the London Institution, there is but one tub employed; but in the improved form, represented in the diagram, it may be removed to a vessel of water, and its maximum effect produced by a subsequent immersion in the dilute acid.

312. As a mere electrical battery, the effect to be derived from this pair of plates is comparatively small; but its powers as an agent for illustrating the connexion between magnetism and electricity are truly astonishing.

313. Magnetic needles, placed at a distance of several feet from the apparatus, were readily put into motion, and deflected from their previous position. The most singular phenomenon, however, which resulted from the series of experiments with this extraordinary instrument, remains to be noticed:—A spiral of wire was connected with the two poles of the battery shown at C, C, and, being placed in a perpendicular direction, a steel cylinder was dropped from the upper end, and this, instead of obeying the ordinary laws of gravitation, was found, after a few oscillations, to take a position somewhere midway between the two extremities of the tube.

# ELECTRO-MAGNETISM.

314. The connexion between galvanism and magnetism must now be examined. The term electro-magnetism has been employed to designate a science which has originated since the commencement of the present century, and which has received no ordinary attention from the continental philosophers, as well as from those of our own country. Amongst those who have done most towards the development of electro-magnetism, we may especially enumerate M. Oersted, Sir Humphry Davy, and professor Barlow, and the latter of these gentlemen has published a very valuable work illustrative of the science.

315. M. Oersted, professor of natural philosophy, and secretary to the Royal Society of Copenhagen, was for many years engaged in enquiries respecting the identity of chemical, electrical, and magnetic forces; and, as early as 1807, proposed to try 'whether electricity the most latent had any action on the magnet.' At that time no experimental proofs of the peculiar opinions he entertained were known; but his constancy in the pursuit of his object, both by reasoning and experiment, was well rewarded in the winter of 1819, by the discovery of a fact of which no previous notice had been taken; but which, when once known, instantly drew the attention of all those who were at all able to appreciate its importance and value.

316. M. Oersted's own account of this discovery has been published in volume xvi. of the

first series of the Annals of Philosophy. It is full of important matter, and contains in few words the results of a great number of observations; and, with his second paper, comprises a very large part of the facts that are as yet known relating to this subject.

317. Upon the excitation of the Voltaic apparatus, by the proper arrangement of its plates and fluid, it is known that certain powers are given to its poles or extremities which enable them, when attached to an electrometer, to show by their divergence a certain tension of electricity; or when connected together by fluids, wires, or other conducting substances, to decompose or heat them. These effects have been known for several years, and are generally attributed to electricity produced by the apparatus; the effects of tension belonging to the insulated state of the poles; those of decomposition and heating to their connected state.

318. When the two poles of such a battery or apparatus are connected by conductors of electricity, the battery is discharged; that is, the tension of the electricity at the poles is lessened, and that, according as the conducting power of the substance is more or less powerful. Good conductors, discharge it entirely and instantly; bad conductors with more or less difficulty; but as the instrument has within itself the power of renewing its first state of tension on the removal of the conducting medium, and that in a very short space of time, it is evident that the connecting substance is continually performing the same office during the whole time of its contact that it did at the first moment, and this whether it be a good or a bad conductor; and it is also evident that it must be in a different state in this situation than when separated from the apparatus. It is important at present rather to consider the action of a good conductor in discharging the battery, as the phenomena to be considered are in that case more energetic. A metallic wire, therefore, may be used to connect the two poles; it will discharge a powerful apparatus; and, consequently, whatever takes place in the connecting medium is here compressed into a very small place. Those who consider electricity as a fluid, or as two fluids, conceive that a current or currents of electricity are passing through the wire, during the whole time it forms the connexion between the poles of an active apparatus. There are many arguments in favor of the materiality of electricity, and but few against it: but still it is only a supposition; and it will be as well to remember, while pursuing the subject of electro-magnetism, that we have no proof of the materiality of electricity, or of the existence of any current through the wire.

319. Whatever be the cause which is active within the connecting wire, whether it be the passage of matter through it, or the induction of a particular state of its parts, it produces certain very extraordinary effects. If small, it becomes heated; and as the size of the wire is diminished, or that of the apparatus increased, the heat rises to an intense degree apparently without any limitation, except from the influence of external circumstances, or the alteration of the wire. Another effect, and it is that to which M. Oersted, here calls attention is, that, if brought towards a magnetic needle, it has the power of attracting and repelling it in a constant manner, and in obedience to certain simple laws.

320. If a magnetic needle be left to take its natural direction, and then a straight portion of the connecting wire be brought above it, and parallel to it, that end of the needle next the negative pole of the battery moves towards the west; and that whether the wire be on the one or the other side of the needle, so that it be above and parallel to it. If the connecting wire be sunk on either side the needle, so as to come into the horizontal plane in which the needle is allowed to move, there is no motion of the needle in that plane; but the needle attempts to move in a vertical circle; and but for the imperfect suspension, and the influence of the earth's magnetism, would do so. When the wire is on the east of the needle, the pole of the needle next the negative end of the battery is elevated; and when on the west of the needle it is depressed. If the connecting wire be now sunk below the level of the needle, similar attractions and repulsions take place, but in opposite directions to those followed when it is above. The pole of the needle opposite the negative end of the battery now moves eastwards, whatever the position of the wire, so that it be restricted as above.

321. That these positions of the magnetic needle may be retained with more facility in the memory, professor Oersted proposed the following formula: 'The pole above which the negative electricity enters is turned to the west; under which, to the east.'

322. M. Oersted subsequently pointed out, what it is easy to see from the above experiments, that the movement of the needle took place in a circle round the connecting wire; and though, in the description of his first experiments, the quantity of declination given to the needle from the wire is expressed by an angle of so many degrees, yet it is afterwards stated to vary with the power of the battery. Whenever the needle is moved in a horizontal or any other circle from the position it naturally assumes, the power of the earth over it tends to restore that position, and is consequently an active force in the present instance opposed to the power of the connecting wire; it therefore lessens the declination the needle would otherwise have. Also when the wire is brought into the same horizontal circle with the needle, its effect over it is shown by the elevation and depression of its opposite ends; and it is the mode of suspension combined with the earth's magnetic power that prevents it from traversing in a vertical circle. But if those interfering circumstances be removed, viz. if the suspension be such as to allow of free motion to the needle in every direction, and the earth's magnetism be rendered null, or counteracted either by the position of the needle, or by the vicinity of another magnet, then a much simpler idea of the relative movements of the wire and needle may be obtained.

323. It is not, perhaps, easy to obtain this perfect state of apparatus, but it is not difficult so to arrange it as to examine the movements first

in one direction, and then in another. It will then be found, if the connecting wires of a sufficiently powerful apparatus be placed near a magnetic needle so as to pass near its centre, that the needle will arrange itself directly across the wire, whatever the previous position of the two; that if the wire be carried round the centre of the needle, or the centre of the needle round the wire, the same relative position of the two will continue; and that the direction of the needle across the wire is not indifferent, but has its poles always in a constant position to the poles of the battery. If the positive pole of a battery be on the right hand, and the negative pole on the left, and a wire be stretched between, connecting them, then a needle above the wire will point the north pole from, and the south towards us; or if below, the south pole from, and the north towards the experimenter. See fig. 5, plate II.

324. If the connecting wire and the needle be represented by two small rods named accordingly, and fastened permanently together, then they will represent the wire and the needle in all positions; for, however one be placed, the other will correspond with it: or if, on the under side of a small square piece of glass, a line be drawn from top to bottom, the upper end being called negative, and the lower positive; and on the upper surface a line be drawn from left to right, the left termination being named south, the right north; then the lower line will always represent the connecting wire, and the upper the needle. Fig. 6.

325. The needle and wire being in this position, if the wire be moved along the needle towards either extremity, strong attractions will take place between it and the pole, notwithstanding the same part of the wire be employed; and the poles in the two positions are contrary to each other. In this case it appears that the same point in the wire has the power of attracting both the north and south pole of the needle. If while the wire is thus situated near the end of the needle, the latter be turned round, so that the pole before there be replaced by the opposite pole, strong repulsions will take place; and that to whichever pole the wire has in the first instance been carried, so that the same point which before attracted both poles will now repel them both. If, when the wire is near the extremity of the needle where the attraction is strongest, it be moved round the end so as to go from one side to the other, keeping the same point constantly towards the needle, its attractive power over the needle will be found to increase as it approaches the end, but remains on one side of it; will diminish as it turns the end; will become null when exactly opposed to the pole; and, as it passes on the other side, will resume repulsive powers, which will be strongest at the extremity of the pole on the opposite side to where the wire was situated at first. Fig. 7.

326. In all these cases the positions assumed by the wire and needle, whether the result of attraction or repulsion, are the same as those before described, except that the wire is now near the end of the needle instead of the middle; and it will be found that all the attractions and repulsions may be reduced to four positions of the needle to the wire, in which it forms tangents with it. In fig. 8, the north pole; in fig. 9, the south pole; if in either of them the poles of the needle be reversed, the tangents remaining in the same direction, repulsion will take place. Hence it is easy to see how any individual part of the wire may be made attractive or repulsive of either pole of the magnetic needle by mere change of position.

327. The magnetic property does not depend upon the metal employed or its form, but is exerted by any of them which forms the circuit between the poles: even a tube filled with mercury is effectual: the only difference is in the quantity of effect produced. It continues also, though the conductor be interrupted by water, unless the interruption be of great extent.

328. The magnetic influence of the wire extends through all sorts of substances, and acts on the needle beyond, just as in common magnetism. It does not act on needles of brass, glass, or gum lac.

329. In a second paper on this subject, M. Oersted shows that not intensity, but quantity, is wanting in the Voltaic apparatus, to produce this effect most eminently. A single galvanic arc is sufficient for the purpose. A plate of zinc, six inches square, placed in a trough of copper, filled with diluted acid, enabled the wire which connected the two metals to act powerfully; and, with a similar arrangement, the zinc plate having a surface of 100 square inches, an effect was produced on the needle at the distance of three feet. He also, in this paper, describes the construction of a Voltaic combination so light, that being suspended, it moved on the approach of a magnet: the motions were in accordance with what has been said, and may easily be conceived.

330. The results obtained by M. Oersted were immediately repeated and confirmed by a great number of philosophers in various places. Of these no one was more active than M. Ampere, in varying experiments, making new ones, and applying to them the most judicious theory.

331. The facts discovered by M. Ampere, though not numerous, are of great importance. He described an experiment, proving that the Voltaic pile itself acted in the same manner as the wire, connecting its two poles; and constructed an instrument which, at the same time that it proved this action, was found to be of great use in experiments on currents of electricity. This was merely a magnetic needle, but from the uses to which it was applied was called a galvanometer. When placed near a pile, or trough, in action, having its poles connected either by a wire, or by introducing them into one cell, it immediately moved, becoming obedient to the battery in the same manner as to the connecting wire; and the motions were such as if the battery were simply a continuation or part of the wire. In consequence of this action, the needle becomes an instrument competent to indicate that state of an active Voltaic pile, and the wire connecting it, which is supposed to be occasioned by currents of electricity, and in which only, magnetism has yet been most perfectly discovered.

332. M. Ampere also announced the fact of the attraction and repulsion of two wires connecting the poles of a battery; and showed, that the magnetic needle, which had previously been used to prove the magnetic attractions and repulsions of the wire, could be replaced by another connecting wire like the first. This discovery seemed to liberate the phenomena of magnetism from any peculiar power resident in the magnet, and to prove its production by electricity alone. When by Oersted's discovery it had been shown that a wire connecting the poles of a Voltaic battery would act on a magnet, attracting and repelling it, just as another magnet would do, it was fair to assume that the wire possessed the powers of the magnet it supplied; and when the second magnet was replaced by another connecting wire, as in Ampere's experiment, and the powers and actions still remained as before, it was perfectly correct to consider these powers and actions as magnetical; so that it became evident that magnetism could be exerted independent of magnets, as they are usually called, and of any of the means of excitation usually employed, but wholly by electricity, and in any good electrically conducting medium.

333. The phenomena with two conductors situate between the poles of the battery are as follows:—When they are parallel to each other, and the same ends of them are similarly related to the battery; viz. when the supposed currents existing in them are in the same direction, then they attract each other; but if the opposite ends be connected with the battery, so that the currents conceived to exist in them are in opposite directions, they repel each other. If also, the one being fixed the other moveable, the currents be sent, or the connexions be made, in opposite directions, then the moveable one will turn round until they are in the same direction. The contrast between these attractions and repulsions, and those usually called electrical, are very striking. The one take place only when the circuit is completed: the other only when it is incomplete. The attractions take place between the similar ends of the wires, and the repulsions between the dissimilar ends; but the electrical attractions take place between dissimilar ends, and the repulsions between similar ends. These take place in vacuo, but those do not. When the magnetic attraction brings the two wires together, they remain in contact; but when electrical attraction brings two bodies together, they separate after the contact.

334. These experiments were varied in several ways by M. Ampere; and the apparatus with which they were made appears, from the plates and description published, to be very delicate, ingenious, and effectual. The general results drawn up by M. Ampere himself from them are, (1.) That two electrical currents attract when they move parallel to each other, and in the same direction; and repel when they move parallel to each other in a contrary direction. (2.) That when the metallic wires, traversed by these currents can only turn in parallel planes, each of the currents tends to direct the other into a situation in which it shall be parallel, and in the same direction. (3.) That these attractions and repulsions are entirely different from the ordinary electrical attractions and repulsions.

335. M. Arago stated to the Royal Academy of Sciences that he had ascertained the attraction of iron filings by the connecting wire of the battery exactly as by a magnet. This fact proved not only that the wire had the power of acting on those bodies already magnetised, but that it was itself capable of developing magnetism in iron that had not previously been magnetised. When the wire in connexion with the poles of the battery was dipped into a heap of filings, it become covered with it, increasing its diameter to the size of a goose-quill; the instant the communication was broken at either pole, the filings dropped off; and when it was re-established, they were re-attracted. This attraction took place with wires of brass, silver, platina, &c., and was so strong as to act on the filings when the wire was brought near them without actual contact. It was shown not to belong to any permanent magnetism in the wire or filings by the inactivity of both when the connexion was not made with the battery; and it was proved not to be electrical attraction by the connecting wire having no power over filings of copper, or brass, or over saw-dust. When soft iron was fused, the magnetism given was only momentary; but on repeating the experiment, with some modification, M. Arago succeeded completely in magnetising a sewing-needle permanently.

336. The theory which M. Ampere had formed, to account for the magnetic phenomena of magnets by electrical powers only, assumed that magnets were only masses of matter, around the axes of which electrical currents were moving in closed curves. This theory led him, when informed by M. Arago of his experiments, to expect a much greater effect if the connecting wire were put into the form of a spiral, and the piece to be magnetised were placed in its axis. According to the theory, in a needle or magnet, pointing to the north, the currents were in the upper part from east to west. In consequence of these expectations, M.M. Ampere and Arago made experiments with spirals or helices, and the results are mentioned in M. Arago's paper, on the communication of magnetism to iron filings in the fifteenth volume of the Annales de Chimie.

337. On twisting a wire round a rod, it may be made to pass either in one direction or the other, giving rise to two distinct but symmetrical helices, which have been named by botanists dextrorsum and sinistrorsum. Though their diameters be equal, and the spirals which compose them have equal inclinations, yet they can never be superposed; for, however they are turned about, their direction is the same. The dextrorsum, or, as we may call it, the right helix, proceeds from the right hand downwards towards the left above the axis; the tendrils of many plants exhibit instances of it, and it is almost exclusively used in the arts: the sinistrorsum, or left helix, proceeds from the left hand downwards towards the right above the axis.

338. Having made some of these helices, one

was connected by its extremities with the poles of a Voltaic battery, and then a needle wrapped in paper placed within it; after remaining there a few minutes, it was taken out, and found to be strongly magnetised; and the effect of a helix above that of a straight connecting wire was found to be very great.

339. Then, with regard to the position of the poles in the magnetised needle, it was found that, whenever a right helix was used, that end of the needle towards the negative end of the battery pointed to the north, and that towards the positive end toward the south; but that with a left helix, that end of the needle towards the positive, pointed north; and the other end south.

340. In order to establish this point, the connecting wire was sometimes formed into one helix, sometimes into two or three, which was readily done by twisting it round a glass tube, or rod, first in one direction, then in another; and when needles previously enclosed in glass tubes were then placed in these helices, the magnetic poles they received were always in accordance with the statement just given. In one case, also, where the connecting wire had been formed into three consecutive helices, the middle one being of course different to the other two, a single piece of steel wire sufficiently long to pass through all three of them being enclosed in a glass tube was placed within them. On being again removed and examined, it was found to have six poles; first, a north pole, a little further on a south pole, then another south pole, a north pole, another north pole, and at the further end a south pole.

341. M. Boisgeraud read a paper to the Royal Academy of Sciences, containing the detail of numerous experiments, most of which, however, are variations of Oersted's first experiments. He remarked, that connecting wires, or arcs, placed any where in the battery, would affect the needle, a result that follows as a consequence from Oersted's and Ampere's experiments. He notices the difference of intensity in the effects produced when bad electrical conductors were employed to complete the circuit, a difference which Oersted himself had pointed out in the case of water. M. Boisgeraud, however, proposed to ascertain the conducting power of different substances by placing them in one of the arcs, cells, or divisions of the battery, and bringing the magnetic needle, or Ampere's galvanometer, towards another arc, viz. to the wire, or other connecting body, used to complete the circuit in the battery. With regard to the positions, M. Boisgeraud's notices of the needle and wire, they are all confirmatory of Oersted's statements.

342. M. Ampere read another memoir on the phenomena of the Voltaic pile, and on the method he intended to pursue in calculating the action of two electrical currents. He also showed the mutual action of two rectilinear electrical currents; viz. of two straight portions of the connecting wires; for it appears that the phenomena of attraction, repulsion, &c., were first observed with spiral wires. These actions, however, are exactly similar; and the view already given of them, as it relates to straight wires, is consequently more simple than the description of the effects with spiral wires can be; viz. considering it as a matter of experiment only, and not of theory.

343. In consequence of the view which M. Ampere had taken of the nature of magnetism as dependent simply upon currents of electricity, it became an important object with him to ascertain the action of the earth upon such currents excited by the Voltaic battery; for, from his theory, he expected that it would be equally efficient in directing these currents as in directing those supposed to exist in the magnetic needle. After some trials, he succeeded in overcoming the obstacles to delicate suspension, contact, &c., and constructed an apparatus in which a part of the wire connecting the two poles of a battery was rendered so light and mobile as to move immediately; the connexion was completed with the pole, and took a direction which, with regard to the earth, was always constant, and in accordance with M. Ampere's theory. An account of these experiments, with the apparatus used in them, was read to the Royal Academy. The first consisted of a wire bent so as to form almost a complete circle of about sixteen inches in diameter; the two extremities were made to approach, and were placed one just beneath the other; and being attached to two steel points, were connected by them with two little basins of platina containing mercury, fixed so as to receive them; only one of the points touched the bottom of the cup in which it was placed; so that the friction was scarcely any, and the mercury secured a good contact. The cups were connected with other wires that passed off to the Voltaic battery; so that it was easy to make this moveable circle connect either one way or the other between the poles; and being enclosed in a glass case, any movement it might receive was readily observed without danger of its resulting from any other cause than the electric action.

344. When the extremities of this apparatus were connected with the poles of a battery, the circle immediately moved, and after some oscillations placed itself in a plane perpendicular to the magnetic meridian of the earth; and, on every repetition of the experiments, the same effect took place. The direction in which it moved depended upon the way in which the connexion had been made with the battery; and if it be assumed that there is a current passing through the wire, from the positive to the negative end, the curve so arranged itself that that current always passed downwards on the eastern side, and upwards on the west. This circle moved round a perpendicular, and, therefore, only represented the direction of the magnetic needle: in order to represent the dip, a wire was formed into a parallelogram, and being fixed to a glass axis was suspended by fine points, and connected as before, so as to move round a horizontal axis, then this axis being placed perpendicular to the magnetic meridian, and the wires being connected with the poles of a battery, the parallelogram immediately moved towards a position in the plane perpendicular to the dipping-needle; when the communication was broken, it returned towards its first position; and when renewed, it resumed the second, evidently indicating the

magnetic influence of the earth over it. In consequence of the difficulty of placing the centre of gravity in the centre of suspension, and keeping it there, this conductor did not take its position exactly in a plane perpendicular to the dipping needle, but approached towards it till in equilibrium between the magnetic and the gravitating power of the earth.

345. M.M. Biot and Savart read a memoir to the Academy of Sciences, the object of which was to determine the law by which a connecting wire acted on magnetised bodies. Small rectangular plates, or cylindrical wires, of tempered steel, were made magnetical by the double touch, and being then suspended by silk-worm threads were placed in differed positions with, and at different distances from, the wire connecting the poles of the battery. The terrestrial magnetism was sometimes combined with that of the wire, sometimes opposed to it, and sometimes neutralised by the vicinity of another magnet. The different positions of equilibrium, and the number of oscillations of the needles, were then observed, and data gained, by which M.M. Biot and Savart were conducted to the following result, which expresses the action exerted by a molecule of austral or boreal magnetism, placed at any distance from a very fine and indefinite cylindrical wire, rendered magnetic by the Voltaic current. Let a line pass from this molecule perpendicularly to the axis of the wire, the force which draws the molecule is perpendicular to this line and to the axis of the wire; its intensity is reciprocal to the distance. The nature of the action is the same as that of a magnetised needle placed on the surface of the wire in a direction determinate and constant in its relation to the direction of the Voltaic current; so that a molecule of boreal magnetism, and a molecule of austral magnetism, would be drawn in different directions, though constantly according to the preceding expression.

346. M. Ampere noticed an effect produced by the connecting wire bent into a helix. This may be easily understood from considering that the direction of the magnetic power is always perpendicular to the conducting wire. When, therefore, the conducting wire is parallel to the axis of the helix, the power is perpendicular to that axis; when the wire forms a circle round the axis, in a plane perpendicular to it, the power is in the direction of the axis; but when, as in the helix, it passes round the axis in a direction intermediate between parallelism and perpendicularity, the direction of the power is of course inclined accordingly. In this case the power may be considered as composed of two portions, one perpendicular to the axis, the other parallel to it. As M. Ampere considered magnets to be assemblages of currents perpendicular to their axes, he wished, in his imitation of them, to do away with that effect due to the extension of the wire in the direction of the axis of the helix, and succeeded in this by making the wire at one end return through the helix so as not to touch it in any part; for, in this position, its magnetic effects being contrary to those belonging to the length of the helix, and also near to them, they neutralised and void each other. An imitation of a magnet was made by forming a helix, and making the wires at the two extremities return through the centre of the helix half way, and then pass out upwards and downwards, so as to form a perpendicular axis on which the whole might move. The extremity of a battery being connected with these two ends of the wire, the helix became magnetical, and was attracted and repelled by a magnet precisely as a real magnet would have been.

347. M. Biot's examination of the effects of magnetism, as impressed by electricity in motion, is too excellent to be passed unnoticed in our chronological account of discoveries in this science.

348. 'When the electric current, evolved from a Voltaic battery, is transmitted through any metallic bodies whatsoever, it gives them instantaneously a magnetic virtue; they become then capable of attracting soft and unmagnetised iron. This curious fact was discovered by M. Oersted. If we expose to these metallic bodies, a magnetic needle, they attract one of its poles, and repel the other, but only relative to the parts of their surface to which the needle is presented. Needles of silver or copper are not affected, but merely those susceptible of being magnetised. These effects subsist only under the influence of the electrical current. If we suspend the circulation of the electricity, by breaking off the communications established between the opposite poles of the Voltaic apparatus, or even if we retard considerably its velocity, by joining its poles with bad conductors, the magnetic power instantly ceases, and the bodies which had received it return to their usual state of indifference.

349. 'This simple sketch already displays many new properties. All the processes hitherto employed to magnetise bodies had produced an effect on only three pure metals, iron, nickel, and cobalt, and on some of their compounds, steel for example, which is merely a carburet of iron. Till now it was never possible to render silver, copper, or the rest of the metals magnetic. But the electric current gives all of them this property; it bestows it transiently by its presence; and, as we shall presently see, it diffuses it through the whole mass, in a manner equally singular, and which has no resemblance to what is produced, when we develope magnetism by our ordinary processes, which consist in longitudinal friction with magnetic bars.

350. 'To produce these novel phenomena in the simplest manner, we must, with M. Oersted, establish a communication between the two extremities of the Voltaic apparatus, by a simple metallic wire, which may be easily directed and bent in all directions. We place afterwards, in the neighbourhood of the battery, a very sensible magnetic needle, horizontally suspended. As soon as this is settled in the direction due to the magnetic force of the terrestrial globe, we take a flexible portion of the conducting, or conjunctive wire, as M. Oersted calls it, and having stretched it parallel to the needle, we bring it gently near it, either from above, from below, from the right, or from the left. We shall see an immediate deviation of the needle; but, what is not the least remarkable circumstance, the direction of this

deviation differs according to the side by which the conjunctive wire approaches it. Duly to comprehend this astonishing phenomenon, and to fix its peculiarities with precision, let us suppose that the conjunctive wire is extended horizontally from north to south, in the very direction of the magnetic direction in which the needle reposed, and let the north extremity be attached to the copper pole of the trough, the other being fixed to the zinc pole. Imagine, also, that the person who makes the experiment looks northward, and consequently towards the copper or negative pole. In this position of things, when the wire is placed above the needle, the north pole of the magnet moves towards the west; when the wire is placed underneath, the north pole moves towards the east; and, if we carry the wire to the right or the left, the needle has no longer any lateral deviation, but it loses its horizontality. If the wire be placed to the right hand, the north pole rises; to the left, its north pole dips; and in thus transporting the conjunctive wire all around the needle, in directions parallel to one another, we merely present it to the needle, by the different sides of its circular contour, without affecting in the least the proper tendency of the needle towards the terrestrial magnetic poles. Since then the deviations observed in these successive positions are first of all directed from right to left, when the wire is above the needle; then from above downwards, when the wire is to the left; from the left to the right, when the wire is beneath; and, finally, from below upwards when it is to the right hand, we must necessarily conclude from these effects, that the wire deranges the needle, by a force emanating from itself, a force directed transversely to the length of its axis, and always parallel to the portion of its circular contour, to which the needle is opposite. M. Oersted drew this inference from his first observations.

351. 'Now this revolutive character of the force, and revolutive according to a determinate direction, in a medium which like silver, copper, or other pure metal, seems perfectly identical in all its parts, is a phenomenon very remarkable, of which we had heretofore only one singular example in the deviations which certain bodies impress on the planes of polarisation of the luminous rays. The first fact of the magnetism, transiently impressed upon the conjunctive wire by the Voltaic current, might have offered itself to a vulgar observer. I do not know whether some traces of this property may not have been previously perceived and indicated; but to have recognised this peculiar character of the force, and to have delineated it, agreeably to its phenomena, without hesitation and uncertainty, is the praise which truly belongs to M. Oersted, and which constitutes a condition entirely new in the movement of electricity.

352. 'As soon as this beautiful discovery was known in France, England, and Germany, it excited the most lively sensation among men of science. One of our colleagues, in particular, M. Ampere, ardently verified it in all its circumstances. Seizing with sagacity the revolutive character of the force impressed on the conjunctive wire, he directed it with judgment, and skilfully developed the consequences which flowed from this property. His researches, which preceded those of the other French philosophers, have considerably occupied the Academy; but as the order of exposition, occasioned by the mutual dependence of the phenomena, hinders me from beginning with them, I have endeavoured to compensate for this inversion by rendering justice at once, to labors which have anticipated and facilitated others.

353. 'In the above experiments which M. Oersted had made, the conjunctive wire is presented to steel needles, previously magnetised. It may be asked, if the action then exercised is proper to the conjunctive wire, as the action of a bar of steel tempered and magnetised is proper to this bar, or if the action is communicated to the wire by the presence of the magnetic needle, as we see soft iron, which exercises no magnetic power of itself, acquire transiently this power in the presence of magnets? To decide this question it was necessary to examine whether a body, not magnetic in itself, but capable of becoming so by influence, soft iron for example, would experience a sensible action at the approach of a conjunctive wire, traversed by the Voltaic current. This was effected by M. Arago, who showed that filings of iron are attracted by these wires; a simple but important fact, which defines clearly one of the characters of the force by which the phenomenon is produced.

354. 'The first thing which we must determine, is the law according to which the force emanating from the conjunctive wire decreases at different distances from its axis. This enquiry has been the object of experiments which I made along with M. Savart, already known to the Academy by his ingenious discoveries in acoustics. We took a small needle of magnetised steel in the form of a parallelogram, and, to ensure its perfect mobility, we suspended it under a glass bell, by a single fibre of the silkworm, and gave it at the same time a horizontal direction. Then, in order that it might be entirely at liberty to obey the force emanating from the conjunctive wire, we screened it from the action of the magnetism of the earth, by placing a magnetised bar at such a distance, and in such a direction, that it exactly balanced this action. Our needle was thereby placed in the same freedom of movement as if there did not exist any terrestrial globe, or as if we had been able to transport ourselves with it to a great distance in space. We now presented it to a conjunctive cylindrical wire of copper, stretched in a vertical direction, and to which we had given such a length, that its extremities necessarily bent in order to attach them to the poles of the electric apparatus, should have, in consequence of their distance, so feeble an action on the needle that it might be neglected with impunity. This disposition represented therefore the effect of an indefinite vertical wire, acting on a horizontal and independent magnetic needle. As soon as the communication of the Voltaic current was completed, the needle turned transversely to the axis of the wire, conformably to the revolutive character indicated by M. Oersted; and it set itself to oscillate around this direction, as a

clock pendulum, moved from the perpendicular, oscillates round the vertical by the effect of gravitation. We counted with an excellent seconds watch of M. Breguet, the time in which a certain number of these oscillations, twenty for example, were performed; and by repeating this observation, when the wire and needle were at different distances, we inferred the decreasing intensity of the force, precisely as we determined, by the oscillations of the same pendulum, the variations of gravity at different latitudes. We thus found that the force exercised by the wire was transverse to its length, and revolution, as M. Oersted had observed; but we discovered besides that it decreased in a ratio exactly proportional to the distance. However, the force which we thus observed was in reality a compound result; for on dividing in imagination the whole length of the conjunctive wire, into an infinity of segments of a very small altitude, we perceive that each segment ought to act on the needle, with a different energy according to its distance and direction. Now these elementary forces are precisely the simple result which it is important to know; for the total force, exercised by the whole wire, is merely the sum of their actions. Calculation enables us to pass from this resultant to the simple action. This has been done by M. Laplace. He has deduced, from our observations, that the individual law of the elementary forces, exercised by each section of the conjunctive wire, was the inverse ratio of the square of the distance; that is, precisely the same that we know to exist in ordinary magnetic actions. This analysis showed that, in order to complete the knowledge of the force, it remained to determine if the action of each section of the wire was the same, at an equal distance, in all directions; or if it was more energetic in a certain direction than in others. I have assured myself by delicate experiments that the last is the case.

355. 'What we now know of the law of the forces, is sufficient for explaining and connecting together a multitude of results, of which I now proceed to indicate briefly some of the most curious. For example, let us conceive as we have done above, an indefinite conjunctive wire, stretched horizontally from south to north. Let us present laterally to it a magnetic needle, of a cylindrical shape, and suspended so that it can take no movement but in the horizontal direction. For greater simplicity, let us withdraw it from the influence of the terrestrial magnetism, by neutralising this influence with the action of a magnet suitably placed. This being done, when the needle rests at the same height as the wire, so as to point exactly to its axis, it is neither attracted nor repelled; but, if we raise it above the wire, it presents one of its poles to it, and makes an effort of approximation. If, on the contrary, we sink it below, the needle turns about, to present its other pole, and is then attracted anew. But, if we constrain it to present the same pole as at first, the needle is repelled, and the effects are precisely inverse on the right and on the left hand of the wire.

356. 'If, instead of transmitting the electrical current across a simple wire, we make it pass through tubes, plates, or other bodies of a sensible breadth, whose surfaces are composed of parallel right lines, we find that all these bodies act on the magnetic needle, as bundles of wires parallel to their length would do; which proves that the power developed in them by the electrical current is exerted freely through their very substance, and is not weakened by their interposition, as the radiation of heat through hot bodies is enfeebled and intercepted by the interposition of these very bodies.

357. 'Instead of leaving the needle in the preceding experiment at liberty to move, fix it invariably, but render the conjunctive wire moveable, by suspending it on two points; then it will be the latter which will move towards the needle, or recede from it. In fact, it is a general law of mechanics, that re-action is always equal to action. If the wire attract or repel the needle in certain circumstances, the needle ought in the same circumstances to attract or repel the wire. This experiment belongs to M. Ampere.

358. 'Now, let us operate no longer with a magnetic needle on the wire placed in its position of mobility, but let us expose it to the magnetic action of the terrestrial globe, which is known to be perfectly similar to that of a common magnet whose poles are very distant. This force will likewise make the conjunctive wire move according to the same laws, at least if it be sufficiently freely suspended, and it will impress on it a determinate direction relative to the plane of the meridian, just as it would direct any other magnetic body. This result was realised by M. Ampere.

359. 'Finally, instead of presenting a conjunctive wire to a magnet, present two conjunctive wires to one another, in parallel positions. Then if the revolutive direction of the force be the same for the two wires, they will both concur in giving one direction to a magnetic needle placed between them; but, if the direction of the revolutive movement be opposite in each, they will tend to turn the needle in opposite directions. These are simple consequences of the law of the forces. Now, on trying these two arrangements, M. Ampere has found that in the first the two wires come together, and that in the second they mutually repel each other. Thence we must make two inferences; first, that the wires exert on each other actions perfectly analogous to those which they exercise on magnetic needles; and next that the distribution of these forces in each of their particles is analogous as to direction, with what it is in magnetic needles themselves. These two new conditions relative to the nature of the force, render this experiment very important.

360. 'In the different arrangements which we have just described, the conjunctive wires and the magnets attract or repel principally by their most contiguous parts; for, with regard to the rest, their distance rapidly diminishes their action. Hence it is evident that we should augment the energy of the effects, if we approximate together the different parts of the conjunctive wire, preserving to them, however, the same general line of action. M. Ampere has also verified this position, by coiling the conjunctive wire in the form of a flattened spiral, on the

plane of whose contours he acts with magnets, as on the side of a single wire.

361. 'Among the arrangements which he has thus formed, one of the most remarkable consists in winding the conjunctive wire around a cylinder of wood or glass, forming an elongated spiral. Then the force emanating from each point of the thread, being always directed transversely to its length, becomes in each element of the spiral perpendicular to the place of the coils, and consequently parallel to the length of the spiral itself. Farther, on account of the revolutive character of the force, all the inner points of the different rings exercise, in the interior of tne spiral, forces which are equal, and operate in the same direction: whilst in their action exteriorly, the forces emanating from the different points of each ring, oppose and weaken each other gently by their obliquity. Thus the result of all these actions ought to be much more energetic within the spiral than outside of it; a consequence which actually happens. If we place in the interior of a spiral, unmagnetic steel needles, they will acquire in a few instants a permanent and very perceptible longitudinal magnetism; whereas, if we place them without the spiral, they suffer no change. This experiment is due to M. Arago. Sir H. Davy, without being acquainted with it, has since succeeded in magnetising small steel needles, by rubbing them transversely on a single conjunctive wire, or even without contact, by placing them at some distance from it. This process does not differ from the preceding, except in using the force of only one wire, a force which the spiral multiplies.

362. 'Since the electricity developed by the friction of our ordinary machines, differs in no other respect from that evolved from the Voltaic apparatus, than that the former is retained and fixed, while the latter is in motion; we find that, whenever we cause the electricity of our machines to flow in a continuous current, it has produced absolutely the same effects as the Voltaic battery. The similarity, or rather the identity, of these two forms of electricity, is manifested likewise in the production of the electro-magnetic phenomena. This has been shown by M. Arago, who transmitted along the spirals of M. Ampere, no longer the Voltaic current, but a succession of very small sparks, drawn from a common electrical machine. Small steel needles, placed in the interior of these spirals, were thus magnetised in a few instants, and the direction of their magnetic polarity was found to be determined in reference to the surfaces charged with the resinous or vitreous electricity, precisely as happens with the copper and zinc poles of the Voltaic apparatus.'

363. We must now revert to the discoveries that were rapidly proceeding in this country. Sir Humphry Davy found, in repeating the experiments of M. Oersted with a Voltaic apparatus of 100 pairs of plates of four inches, that the south pole of a common magnetic needle placed under the communicating wire of platinum was strongly attracted by the wire, and remained in contact with it, so as entirely to alter the direction of the needle, and to overcome the magnetism of the earth. This he could only explain by supposing that the wire itself became magnetic during the passage of the electricity through it, and direct experiments, which were immediately made, proved that this was the case. He threw some iron filings on a paper, and brought them near the communicating wire, when immediately they were attracted by the wire, and adhered to it in considerable quantities, forming a mass round it ten or twelve times the thickness of the wire: on breaking the communication they instantly fell off, proving that the magnetic effect depended entirely on the passage of the electricity through the wire. The same experiment was tried on different parts of the wire, which was seven or eight feet in length, and about the twentieth of an inch in diameter, and the iron filings were found every where attracted by it; and, making the communication with wires between different parts of the battery, iron filings were attracted, and the magnetic needle affected in every part of the circuit.

364. It was easy to imagine that such magnetic effects could not be exhibited by the electrified wire without being capable of permanent communication to steel. Sir Humphry fastened several steel needles, in different directions, by fine silver wire to a wire of the same metal, of about the thirtieth of an inch in thickness, and eleven inches long, some parallel, others transverse, above and below in different directions; and placed them in the electrical circuit of a battery of thirty pairs of plates, of nine inches by five, and tried their magnetism by means of iron filings: they were all magnetic; those which were parallel to the wire attracted filings in the same way as the wire itself, but those in transverse directions exhibited each two poles, which, being examined by the test of delicate magnets, it was found that all the needles that were placed under the wire (the positive end of the battery being east) had their north poles on the south side of the wire, and their south poles on the north side; and that those placed over had their south poles turned to the south, and their north poles turned to the north; and this was the case whatever was the inclination of the needles to the horizon. On breaking the connexion, all the steel needles that were on the wire in a transverse direction retained their magnetism, which was as powerful as ever, while those which were parallel to the silver wire appeared to lose it at the same time as the wire itself.

365. He attached small longitudinal portions of wires of platinum, silver, tin, iron, and steel, in transverse directions, to a wire of platinum that was placed in the circuit of the same battery. The steel and the iron wire immediately acquired poles in the same manner as in the last experiment; the other wires seemed to have no effect, except in acting merely as parts of the electrical circuit; the steel retained its magnetism as powerfully after the circuit was broken as before; the iron wire immediately lost a part of its polarity, and in a very short time the whole of it.

366. The battery was placed in different directions as to the poles of the earth; but the effect was uniformly the same. All needles placed transversely under the communicating

wires, the positive end being on the right hand, had their north poles turned toward the face of the operator, and those above the wire their south poles; and on turning the wire round to the other side of the battery, it being in a longitudinal direction, and marking the side of the wire, the same side was always found to possess the same magnetism; so that in all arrangements of needles transversely round the wire, all the needles above had north and south poles opposite to those below, and those arranged vertically on one side, opposite to those arranged vertically on the other side.

367. It was found that contact of the steel needles was not necessary, and that the effect was produced instantaneously by the mere juxtaposition of the needle in a transverse direction, and that through very thick plates of glass: and a needle that had been placed in a transverse direction to the wire merely for an instant, was found as powerful a magnet as one that had been long in communication with it.

368. Sir Humphry placed some silver wire of one-twentieth of an inch, and some of one-fiftieth, in different parts of the Voltaic circuit when it was completed, and shook some steel filings on a glass plate above them: the steel filings arranged themselves in right lines, always at right angles to the axis of the wire; the effect was observed, though feebly, at the distance of a quarter of an inch above the thin wire, and the arrangement in lines was nearly to the same length on each side of the wire.

369. He ascertained, by several experiments, that the effect was proportional to the quantity of electricity passing through a given space, without any relation to the metal transmitting it: thus, the finer the wires the stronger their magnetism.

370. A zinc plate of a foot long, and six inches wide, arranged with a copper plate on each side, was connected by a very fine wire of platinum; and the plates were plunged an inch deep in diluted nitric acid. The wire did not sensibly attract fine steel filings. When they were plunged two inches, the effect was sensible; and it increased with the quantity of immersion. Two arrangements of this kind acted more powerfully than one; but when the two were combined, so as to make the zinc and copper plates but parts of one combination, the effect was very much greater. This was shown still more distinctly in the following experiment:—Sixty zinc plates with double copper plates were arranged in alternate order, and the quantity of iron filings which a wire of a determinate thickness took up observed: the wire remaining the same, they were arranged so as to make a series of thirty; the magnetic effect appeared more than twice as great; that is, the wire raised more than double the quantity of iron filings.

371. The magnetism produced by Voltaic electricity seems (the wire transmitting it remaining the same) exactly in the same ratio as the heat; and however great the heat of a wire, its magnetic powers were not impaired. This was distinctly shown in transmitting the electricity of twelve batteries of ten plates each of zinc, with double copper arranged as three, through fine platinum wire, which, when so intensely ignited as to be near the point of fusion, exhibited the strongest magnetic effects, and attracted large quantities of iron filings, and even small steel needles from a considerable distance.

372. As the discharge of a considerable quantity of electricity through a wire seemed necessary to produce magnetism, it appeared probable that a wire electrified by the common machine would not occasion a sensible effect; and this was found to be the case, on placing very small needles across a fine wire, connected with a prime conductor of a powerful machine and the earth. But, as a momentary exposure in a powerful electrical circuit was sufficient to give permanent polarity to steel, it appeared equally obvious, that needles placed transversely to a wire at the time that the electricity of a common Leyden battery was discharged through it, ought to become magnetic, and this was actually the case, and according to precisely the same laws as in the Voltaic circuit; the needle under the wire, the positive conductor being on the right hand, offering its north pole to the face of the operator, and the needle above exhibiting the opposite polarity.

373. So powerful was the magnetism produced by the discharge of an electrical battery of seventeen square feet, highly charged, through a silver wire of one-twentieth of an inch, that it rendered bars of steel two inches long, and from one-twentieth to one-tenth in thickness, so magnetic, as to enable them to attract small pieces of steel wire or needles; and the effect was communicated to a distance of five inches above or below, or laterally from the wire, through water, or thick plates of glass, or metal electrically insulated.

374. The facility with which experiments were made with the common Leyden battery, enabled Sir Humphry Davy to ascertain several circumstances which were easy to imagine, such as that a tube filled with sulphuric acid, of one-fourth of an inch in diameter, did not transmit sufficient electricity to render steel magnetic; that a needle placed transverse to the explosion through air, was less magnetised than when the electricity was passed through wire; that steel bars exhibited no polarity (at least at their extremities) when the discharge was made through them, as part of the circuit, or when they were placed parallel to the discharging wire; that two bars of steel fastened together, and having the discharging-wire placed through their common centre of gravity, showed little or no signs of magnetism after the discharge, till they were separated, when they exhibited their north and south poles opposite to each other, according to the law of position.

375. These experiments distinctly showed, that magnetism was produced whenever concentrated electricity passed through space; but the precise circumstances, or law of its production, were not obvious from them. When a magnet is made to act on steel filings, these filings arrange themselves in curves round the poles, but diverge in right lines; and in their adherence to each other form right lines, appearing as spicula. In the attraction of the filings round the

wire in the Voltaic circuit, on the contrary, they form one coherent mass, which would probably be perfectly cylindrical, were it not for the influence of gravity. In first considering the subject, it appeared to Sir Humphry, that there must be as many double poles as there could be imagined points of contact round the wire; but when he found the north and south poles of a needle uniformly attracted by the same quarters of the wire, it appeared to him that there must be four principal poles corresponding to these four quarters. Dr. Wollaston has, however, pointed out that there is nothing definite in the poles; that the phenomena may be explained, by supposing a kind of revolution of magnetism round the wire, depending for its direction upon the position of the negative and positive sides of the electrical apparatus.

376. To gain some light upon this matter, and to ascertain correctly the relations of the north and south poles of steel, magnetised by electricity to the positive and negative state, Sir Humphry Davy placed short steel needles round a circle made on pasteboard, of about two inches and a half in diameter, bringing them near each other, though not in contact; and fastening them to the pasteboard by thread, so that they formed the sides of a hexagon inscribed within the circle. A wire was fixed in the centre of this circle, so that the circle was parallel to the horizon, and an electric shock was passed through the wire, its upper part being connected with the positive side of a battery, and its lower part with the negative. After the shock all the wires were found magnetic, and each had two poles; the south pole being opposite to the north pole of the wire next to it, and vice versa; and when the north pole of a needle was touched with a wire, and that wire moved round the circle to the south pole of the same needle, its motion was opposite to that of the apparent motion of the sun.

377. A similar experiment was tried with six needles arranged in the same manner, with only this difference, that the wire positively electrified was below. In this case the results were precisely the same, except that the poles were reversed; and any body, moved in the circle from the north to the south pole of the same needle, had its direction from east to west.

378. A number of needles were arranged as polygons in different circles round the same piece of pasteboard, and made magnetic by electricity; and it was found that in all of them, whatever was the direction of the pasteboard, whether horizontal or perpendicular, or inclined to the horizon, and whatever was the direction of the wire with respect to the magnetic meridian, the same law prevailed; for instance, when the positive wire was east, and a body was moved round the circle from the north to the south poles of the same wire, its motion (beginning with the lower part of the circle) was from north to south, or with the upper part from south to north; and when the needles were arranged round a cylinder of pasteboard so as to cross the wire, and a pencil-mark drawn in the direction of the poles, it formed a spiral.

379. It was perfectly evident from these experiments, that as many polar arrangements may be formed as chords can be drawn in circles surrounding the wire.

380. Supposing powerful electricity to be passed through two, three, four, or more wires, forming part of the same circuit parallel to each other in the same plane, or in different planes, it could hardly be doubted that each wire, and the space around it would become magnetic in the same manner as a single wire, though in a less degree; and this was found to be actually the case. When four wires of fine platinum were made to complete a powerful Voltaic circuit, each wire exhibited its magnetism in the same manner, and steel filings on the sides of the wires opposite attracted each other.

381. As the filings on the opposite sides of the wire attracted each other in consequence of their being in opposite magnetic states, it was evident, that if the similar sides could be brought in contact, steel filings upon them would repel each other. This was very easily tried with two Voltaic batteries, arranged parallel to each other, so that the positive end of one was opposite to the negative end of the other. steel filings upon two wires of platinum joining the extremities strongly repelled each other. When the batteries were arranged in the same order, viz. positive opposite to positive, they attracted each other; and wires of platinum (without filings) and fine steel wire (still more strongly) exhibited similar phenomena of attraction and repulsion under the same circumstances.

382. As bodies magnetised by electricity put a needle in motion, it was natural to infer that a magnet would put bodies magnetised by electricity in motion, and this was found to be the case. Some pieces of wire of platinum, silver, and copper were placed separately upon two knife edges of platinum, connected with two ends of a powerful Voltaic battery, and a magnet presented to them; they were all made to roll along the knife edges, being attracted when the north pole of the magnet was presented, the positive side of the battery being on the right hand, and repelled when it was on the left hand, and vice versa, changing the pole of the magnet. Some folds of gold leaf were placed across the same apparatus, and the north pole of a powerful magnet held opposite to them; the folds approached the magnet, but did not adhere to it. On the south pole being presented, they receded from it.

383. Sir Humphry Davy, in continuing his researches on the magnetic phenomena produced by electricity, found that these phenomena were precisely the same, whether the electricity was small in quantity, and passing through good conductors of considerable magnitude; or, whether the conductors were so imperfect as to convey only a small quantity of electricity; and in both cases they were neither attractive of each other, nor of iron filings, and not affected by the magnet, and the only proof of their being magnetic was their occasioning a certain small deviation of the magnetised needle.

384. Thus, a large piece of charcoal placed in the circuit of a very powerful battery, being a very bad conductor compared with the metals,

would not affect the compass needle at all, unless it had a very large contact with the metallic part of the circuit; and if a small wire was made to touch it in the circuit, only in a few points, that wire did not gain the power of attracting iron filings; though, when it was made to touch a surface of platinum foil coiled round the end of the charcoal, a slight effect of this kind was produced. And in a similar manner fused hydrate of potassa, one of the best of the imperfect conductors, could never be made to exert any attractive force on iron filings, nor could the smallest filaments of cotton, moistened by a solution of hydrate of potassa, placed in the circuit, be made to move by the magnet; nor did steel needles floating on cork on an electrised solution of this kind, placed in the Voltaic circuit, gain any polarity; and the only proof of the magnetic powers of electricity passing through such a fluid, was afforded by its effect upon the magnetised needle, when the metallic surfaces, plunged in the fluid, were of considerable extent. That the mobility of the parts of fluids did not interfere with their magnetic powers, as developed by electricity, was proved by electrifying mercury and Newton's metal fused in small tubes. These tubes, placed in a proper Voltaic circuit, attracted iron filings, and gave magnetic powers to needles; nor did any agitation of the mercury or metal within, either in consequence of mechanical motion or heat, alter or suspend their polarity.

385. Imperfect conducting fluids do not give polarity to steel when electricity is passed through them; but electricity passed through air produces this effect. Reasoning on this phenomenon, and on the extreme mobility of the particles of air, Sir Humphry Davy concluded, as M. Drago had likewise done from other considerations, that the Voltaic current in air would be affected by the magnet.

386. Mr. Pepys charged the great battery of the London Institution, consisting of 2000 double plates of zinc and copper, with a mixture of 1168 parts of water, 108 parts of nitrous acid, and twenty-five parts of sulphuric acid; the poles were connected by charcoal, so as to make an arc, or column of electrical light, varying in length from one to four inches, according to the state of rarefaction of the atmosphere in which it was produced; and a powerful magnet being presented to this arc, or column, having its pole at a very acute angle to it, the arc, or column, was attracted or repelled with a rotatory motion, or made to revolve by placing the poles in different positions, being repelled when the negative pole was on the right hand, by the north pole of the magnet, and attracted by the south pole, and vice versa.

387. It was proved by several experiments that the motion depended entirely upon the magnetism, and not upon the electrical inductive powers of the magnet; for masses of soft iron, or of other metals, produced no effect.

388. The electrical arc, or column of flame, was more easily affected by the magnet, and its motion was more rapid when it passed through dense than through rarefied air, and in this case, the conducting medium or chain of aeriform particles was much shorter.

389. We must now again revert to the continental philosophers. M. Von Buch, of Utrecht, while engaged in repeating the experiments of Oersted and others, obtained results according with them, except in one instance of difference with Oersted. M. Oersted says, that 'if the uniting wire be placed perpendicularly to the plane of the magnetic meridian, whether above or below it, the needle remains at rest, unless it be very near the pole; in that case, the pole is elevated when the entrance is from the west side of the wire, and depressed when from the east.' M. Von Buch points out that this state of rest does not continue in two of the four positions of the wire. When the connecting wire is beneath the centre of the needle, and the positive current is from east to west, the needle remains unmoved. When the current is from west to east, it performs half a revolution. On the contrary, the connecting wire being above the current from east to west, makes the needle turn half way round; while that from west to east leaves the needle unmoved. M. Von Buch conceives the difference of his results and M. Oersted's to depend upon the superior power of his apparatus; and indeed it is sufficiently evident that the incompleteness of Mr. Oersted's results depended upon the weakness of his pile. The attractions and repulsions, or the elevations and depressions, he speaks of when the wire was brought near the poles proves the existence of that action which, in M. Von Buch's experiments, was strong enough to turn the needle round; and, if the position of the wire and needle in these experiments be compared with the positions deduced from M. Oersted's experiments, it will be found that, in two of the cases, those pointed out by M. Von Buch, it was necessary a half revolution of the needle should take place to bring it into a state of equilibrium with the wire in those positions.

390. M. Von Buch, also, appears to have ascertained the effect of common electricity in producing magnetism without a previous knowledge of what had been done by others in that way, and succeeded in producing the effect by a smaller power than had before been used for that purpose. He found that a strong discharge was not necessary, nor even a Leyden phial; but, fixing a helix between the prime conductor of a machine and another insulated conductor, placing a steel needle in it, and then drawing sparks from the latter conductor, the needle became magnetic. One single turn of a machine, with two discs, eighteen inches in diameter, was sufficient to make the needle evidently magnetic.

391. In Italy, many experiments relating to magnetism by electricity had been made, and which, though new at the time to those who made them, had been previously made by others. A series was made by M.M. Gazzeri, Ridolfi, and Antinori, at Florence. The results are as follows: needles placed in helices connected with the poles of the battery received their full magnetisation in one minute. Needles on the outside of the helices would receive no magne-

tism, unless there was one or more also within, and then they became magnets with their poles in opposite directions to the poles of the inner magnet. The helix was changed into a square form, by having its wire wrapped round a parallelopiped; the magnetising effect remained the same. A needle and a long wire of platina were wrapped in a sheet of tin-foil, and that part which contained the needle introduced into a spiral of copper wire; the circuit was then made by the platina wire without the copper spiral; being in connexion with either pole, the needle became magnetised. A spiral of copper wire, with a needle in it, was placed on the surface of a basin of mercury, and the mercury then made part of the circuit: the needle became feebly magnetic. Sparks from a common machine, taken through a helix containing a steel needle, made the needle magnetic. These philosophers appear to have found that the connecting wire placed in other parts of the battery than from end to end would not magnetise needles. There was however, probably, some mistake in this.

392. M. la Borne, in repeating Arago's experiments, varied the use of the helix, by making it of iron, and putting it round the straight wire, through which an electrical discharge was made. The helix in this case became the needle to be magnetised, and it was found to be a strong magnet, the poles being in the positions so often referred to. Such a magnet is flexible and elastic, and may be doubled, lengthened, or shortened: on bringing the two poles together, its action on a magnetic needle was much diminished.

393. M. Berzelius described an experiment, which consisted in placing a thin leaf of tin, eight inches long and two inches wide, parallel to, and in the plane of, the meridian, and in that position connecting it with the elements of a Voltaic circle. A magnetic needle brought near the lower edge of this plate was thrown 20° from the magnetic meridian. On moving it slowly upwards, it took its natural position, when level with the middle of the plate, except that it was raised at one end, and depressed at the other; and, when near the upper edge, it moved 20° from the magnetic meridian in the opposite direction to what it did below. When the needle was moved up and down on the opposite side of the plate, the same deviation and effects took place, but in opposite directions. A small portion of the upper edge of the leaf was cut, and turned upwards, forming a projection above the edge. The needle, brought within equal distance of this projection and the edge, was more affected by the former than the latter.

394. Then, using a square plate of tin, and forming the connexion at opposite angles, it was found on examination that the intervening angles acted more powerfully on the needle than any other parts—'a circumstance which proves,' M. Berzelius says, 'that the magnetic polarity of the current goes to opposite extremities, as happens with electric polarity, and in artificial magnets.'

395. The tin band, or leaf, placed in a horizontal plane, and in the magnetic meridian, acted on the needle just as a wire would have done. The greatest deviation of the needle was immediately under or above the middle of the leaf, and the edges acted as in the former position. The positions assumed by the needles in these experiments was exactly what would be expected. The experiments received all their interest from the way in which their maker applied them to support his particular opinion, and apart from that had not much new in them. M. Berzelius thought that a round wire, when made the conductor, presented a more complicated case than when a square one, or a parallelopiped, was used.

396. In 1823 a paper was published by Sir Humphry Davy on the subject of electro-magnetism, which is of too important a character to admit of abridgment. He says, 'Immediately after Mr. Faraday had published his ingenious experiments on electro-magnetic rotation, I was induced to try the action of a magnet on mercury connected in the electrical circuit, hoping that, in this case, as there was no mechanical suspension of the conductor, the appearances would be exhibited in their most simple form; and I found that when two wires were placed in a basin of mercury perpendicular to the surface, and in the Voltaic circuit of a battery with large plates, and the pole of a powerful magnet held either above or below the wires, the mercury immediately began to revolve round the wire as an axis, according to the common circumstances of electro-magnetic rotation, and with a velocity exceedingly increased when the opposite poles of two magnets were used, one above, the other below.

397. 'Masses of mercury, of several inches in diameter, were set in motion, and made to revolve in this manner, whenever the pole of the magnet was held near the perpendicular of the wire; but, when the pole was held above the mercury between the two wires, the circular motion ceased, and currents took place in the mercury in opposite directions, one to the right, and the other to the left, of the magnet. These circumstances, and various others which it would be too tedious to detail, induced me to believe that the passage of the electricity through the mercury, produced motions independent of the action of the magnet; and that the appearances which I have described were owing to a composition of forces.'

398. Sir Humphry says, 'I endeavoured to ascertain the existence of these motions in the mercury, by covering its surface with weak acids; and diffusing over it finely divided matter, such as the seeds of lycopodium, white oxide of mercury, &c.; but without any distinct result. It then occurred to me, that from the position of the wires, currents, if they existed, must occur chiefly in the lower, and not the upper surface of the mercury: and I consequently inverted the form of the experiment. I had two copper wires, of about one-sixth of an inch in diameter, the extremities of which were flat and carefully polished, passed through two holes, three inches apart, in the bottom of a glass basin, and perpendicular to it; they were cemented into the basin, and made non-conductors by sealing-wax, except at their polished ends; the basin was then filled with mercury, which stood about a tenth or twelfth of an inch above the wires. The wires were now placed in a powerful Voltaic circuit. The moment the contacts were made, the phe-

nomenon, which is the principal object of this paper, occurred: the mercury was immediately seen in violent agitation; its surface became elevated into a small cone above each of the wires; waves flowed off in all directions from these cones; and the only point of rest was apparently where they met in the centre of the mercury between the two wires. On holding the pole of a powerful bar-magnet at a considerable distance (some inches) above one of the cones, its apex was diminished and its base extended: by lowering the pole further, these effects were still further increased, and the undulations were feebler. At a smaller distance the surface of the mercury became plane; and rotation slowly began round the wire. As the magnet approached, the rotation became more rapid, and, when it was about half an inch above the mercury, a great depression of it was observed above the wire, and a vortex, which reached almost to the surface of the wire.

399. 'In the first experiment which I made, the conical elevations or fountains of mercury were about the tenth or twelfth of an inch high, and the vortices apparently as low; but, in the experiments made at the London Institution, the mercury being much higher above the wire, the elevations and depressions were much more considerable, amounting to the fifth or sixth of an inch. Of course the rotation took place of either pole of a magnet, or either wire, or both together, according to the well-known circumstances which determine these effects.

400. 'To ascertain whether the communication of heat diminishing the specific gravity of the mercury, had any share in these phenomena, I placed a delicate thermometer above one of the wires in the mercury, but there was no immediate elevation of temperature; the heat of the mercury gradually increased, as did that of the wires; but this increase was similar in every part of the circuit. I proved the same thing more distinctly, by making the whole apparatus a thermometer terminating in a fine tube filled with mercury. At the first instant that the mercury became electro-magnetic, there was no increase of its volume.

401. 'This phenomenon cannot be attributed to common electrical repulsion; for, in the electro-magnetic circuit, similar electrified conductors do not repel, but attract, each other; and it is in the case in which conductors in opposite states are brought near each other on surfaces of mercury that repulsion takes place.

402. 'Nor can the effect be referred to that kind of action which occurs when electricity passes from good into bad conductors, as in the phenomena of points electrified in air, as the following facts seem to prove. Steel wires were substituted for copper wires, and the appearances were the same in kind, and only less in degree; without doubt, in consequence of a smaller quantity of electricity passing through the steel wire: and by comparing the conducting powers of equal cylinders of mercury and steel in glass tubes, by ascertaining the quantity of iron filings they attracted, it was found that the conducting powers of mercury were higher that those of steel; the first metal taking up fifty-eight grains of iron filings, and the second only thirty-seven.

403. 'Again, fused tin was substituted for mercury in a porcelain vessel, into which wires of copper and steel were alternately ground and fixed; the elevations were produced as in the mercury, and the phenomena of rotation by the magnet: and it was found by direct experiment, that the conducting powers of the tin, at and just before its point of fusion, did not perceptibly differ, and that they were much higher than those of mercury. Lastly, the communication was made from the battery by two tubes having nearly the same diameter as the wires, filled with mercury, so that the electricity, for some inches before it entered the basin, passed through mercury; and still the appearances continued the same.

404. 'From the rapidity of the undulations round the points of the cones, I thought they would put in motion any light bodies placed above the mercury; but I could not produce the slightest motion in a very light wheel hung on an axle; and when fine powders of any kind were strewed upon the surface, they merely underwent undulations, without any other change of place; and fine iron filings, strewed on the top of the cone, arranged themselves in right lines at right angles to the line joining the two wires, and remained stationary, even on the centre of the cone. The effect, therefore, is of a novel kind, and in one respect seems analogous to that of the tides. It would appear as if the passage of the electricity diminished the action of gravity on the mercury. And that there is no change of volume of the whole mass of the mercury, appears from the experiment; and this was shown likewise by enclosing the apparatus in a kind of manometer terminating in a fine tube containing air enclosed by oil; and which, by its expansion or contraction, would have shown the slightest change of volume in the mercury: none, however, took place when the contacts were alternately made and broken, unless the circuit was uninterrupted for a sufficient time to communicate sensible heat to the mercury.'

405. We may now direct the reader's attention to professor Barlow's admirable collection of experimental illustrations of this science. Mr. Barlow published a very interesting Treatise on Magnetic Attractions in 1823, but a new edition has since appeared. We shall only advert to the last section of the third part, referring our readers to the work itself for the fullest information on the subject.

406. We may commence with the most simple experiment, and show Mr. Barlow's mode of magnetising a steel bar. Take a piece of steel wire, as for example a sewing needle, and dip its ends first into steel or iron filings, in order to ascertain that it has no magnetism already in it, which will be the case if the particles of iron do not adhere to it; if they do, another needle must be tried, till one is found free from every species of magnetic action; this being done, connect the ends of the battery by the conducting wire, C Z and place the needle, N S, across it, fig. 10, plate II., drawing the latter backward and forward a few times, and it will be found to have acquired the magnetic property; for, on

immersing its extremities again in the filings, they will be found to adhere to it, in the same manner as to a needle magnetised in the usual way.

407. This very interesting experiment is strictly conformable to professor Barlow's hypothesis; for, according to this, the action of the galvanic particles in the wire, being tangential, will act upon the latent magnetic particles in the needle, in the direction of its length, and cause a displacement of them, precisely in the same manner as would be done by a magnet; and also, as in that case, the cohesive power of the steel preventing the return of the fluids to their natural state, the needle will remain magnetic.

408. This experiment was performed nearly at the same time by Sir H. Davy, and M. Ampere; but Sir H. Davy also succeeded in effecting the same with the common electrical machine, and showed that the magnetism might be excited at considerable distances, and consequently not only without rubbing the needle on the wire as we have described, but even without the contact. It requires, however, to effect this at the distances here alluded to, a very powerful apparatus.

409. If the needle be made a part of the galvanic circuit, or if it be placed lengthwise of the wire, no perceptible permanent magnetic power will be developed, which is also consistent with the hypothesis; because, in this case, the action of the wire will be transverse of the needle, which is the least favorable direction for the development of the magnetic power; the tendency of the action being to place the poles transversely, instead of lengthwise.

410. To ascertain the polarity of needles magnetised as in the last experiment, the wire and needle being placed as in the last figure, that is, the needle being above the wire, and Z denoting the zinc end of a battery of two plates only, it will be found that the extremity N will attract the south end of a compass needle, and the extremity S the north end; in short, that the north poles of the latent magnetic particles have been carried towards the left hand, and the south towards the right hand.

411. Let the needle now be placed under the wire, instead of being placed over it, and in other respects the process described in the last example repeated, and it will be found that the polarity of the needle will be exactly the reverse of that in the last experiment, which ought to be the case according to the principle of the preceding experiment; because by this the north polarity is always carried to the left hand of the observer, who conceives himself to form the galvanic circuit, his head being towards the zinc end, and his face towards the magnet; for thus, his position being now the reverse of what it was in the preceding experiment, the polarity ought to be the reverse also.

412. If we wish to magnetise a needle by placing it in a spiral conducting wire, let ZC (fig. 11) represent a conducting wire bent into a spiral form, and let the needle *ns* be placed either naked in the spiral, or enclosed in a glass tube, or in a tube of any other matter; make the connexion with the battery, and in an instant it will be found that the needle *ns* has become strongly magnetic, having its poles posited, as shown in the figure, viz. having its north end towards the zinc extremity of the battery.

413. This is of course precisely similar to the first experiment, the only difference being that, by means of the spiral form given to the wire, the action upon the needle is repeated as many times as there are spires of the wire covered by it; the power excited is therefore proportionably stronger, and the magnetism more quickly communicated. The explanation of the effect produced is exactly the same as in the last experiment. If the direction of the contact be changed, by supposing Z to communicate with the copper side of the battery, the effect will be in all respects the same, except that the polarity of the needle will be reversed. The end towards Z, in this case, becoming the south instead of the north pole. Or if a spiral, having its spires turned the contrary way, as shown in fig. 12, be used, and Z be supposed to communicate with the zinc side of the battery, the polarity will also be the reverse of that in the first case; viz. the poles will have the direction marked in the figure; and if here again the contact be changed by connecting Z with the copper side, the poles will be once more inverted, and have the same direction as at first. These facts, as we have stated above, are explained exactly in the same manner as those for the single wire.

414. In performing this experiment, Mr. Barlow employed a glass tube about five inches in length and half an inch in diameter; and it was observed, when the needle was placed in it, so that one half of it projected beyond the end that the moment the plates reached the acid, the needle was drawn instantly to the middle of the tube, and while the contact was continued it was held suspended in the centre of the tube when the latter was held vertically, the suspending power of the spiral exceeding the power of gravity.

415. This effect is very curious, because the needle here remains suspended in the open space, directly in the axis of the tube, and not attached to either sides as in the usual cases of suspension by attraction.

416. To examine the effects of a spiral conducting wire on a floating magnetised needle, let a wire be wound about a glass tube of about half or three-quarters of an inch diameter, and hang it within a basin of water, as shown in fig. 13, so that the surface of the water rises to about the axis of the bore; then having pierced a small piece of cork with a needle previously magnetised, so as just to preserve it from sinking when immersed in the basin, make the connexion with the battery. The needle will instantly be agitated, and will soon arrange itself in front of the spiral in a direction parallel to its axis, and then suddenly dart into the interior of the tube with a force nearly sufficient to carry it to the other extremity; it then returns again towards the other end, and at length becomes stationary in the middle of the axis, arranging itself exactly parallel to it.

417. If the spirals have the direction shown in the figure, and Z communicates with the zinc side, the needle, if placed near the extremity of the tube A, will enter with its south

end; if placed near the other extremity it will enter with its north end; but, if the direction of the spiral be changed, the needle will enter in both cases the reverse way, as it will also if the direction of the spires remain the same, but the contact be changed. This experiment will succeed equally well if the tube be placed upright in the water; the needle will then dive like a fish, and remain below till the contact is broken.

418. This entertaining and instructive experiment is due to Mr. Faraday; the explanation of it by the previous hypothesis is obvious, for the north pole of the particles of the needle being carried to the left of an observer conceiving himself coinciding with the direction of the wire, and with his head towards Z, all the effects ought to take place precisely as above stated. M. Ampere had assimilated a spiral wire of this kind with an actual magnet, and Mr. Faraday instituted the above experiment to prove that there was not that identity which had been assumed; for, by suspending a hollow cylindrical magnet in the same way, the needle was always attracted to the nearest extremity of its edge, and indicated no tendency to enter the tube.

419. To show the effect produced by a galvanic wire on steel or iron filings, we must strew a quantity of iron dust or filings on a table, and bring the connecting wire near to them, when the filings will immediately be affected by the action of the wire, some few flying towards it, and adhering to it as a magnet; and, if the wire be brought into actual contact with them, a very considerable quantity may be taken up by it, exactly the same as at the extremity of a bar magnet; but the moment the contact is broken the filings fall.

420. In order to produce the best effect in this experiment, the wire intended to be operated upon should be smaller than the conducting part of the circuit. This latter, in all cases, is the better for being stout, at least three-sixteenths of an inch in diameter; but in this, as in several other experiments, it is best to have the extremities of the wires terminated by a much smaller wire, wound round the former as a spiral, or by simple contact; for by this means, the transmission being made through a smaller space, the intensity of action is proportionably increased.

421. This experiment is due to M. Arago, and it seems at first sight somewhat at variance with Mr. Barlow's hypothesis; because we have here an appearance of actual attraction between the iron and the wire, whereas we have supposed that there is no attraction between them. A little consideration will, however, show, that instead of contradicting, this fact will serve to confirm the hypothesis in question.

422. Let us, for example, conceive W, fig. 14, to denote the section of our conducting wire descending vertically from the zinc end of the battery; then, the first and direct action of this wire will be to excite magnetism in any small particle of iron, *n s*, according to the direction indicated by the letters in the figure.

423. After which, the action of the wire will be to urge the point *n* in the line *n n*, perpendicular to *n* W, and the point *s*, in the line *s s*, perpendicular to *s* W; and, in consequence of the combined action of these forces, the particle *n s* ought necessarily to approach the wire in the same way as it would do by a direct attractive force. This effect is therefore still consistent with our hypothesis, and strongly confirmatory of it.

424. We have seen that, by giving the conducting wire a spiral form, its power of magnetism is much increased; and in the same way the power of the wire on the iron filings may be rendered very great. The best form for the spiral, however, here, is that in which the wire lies all in one plane, as was shown in a previous figure.

425. This, being connected by its two extremities with the poles of the battery, will take up an astonishing quantity of filings, which, by their reciprocal attraction towards each other, exhibit the most pleasing appearance.

425*. To exhibit the rotation of a magnet round a galvanic wire, let A B E D, fig. 15, represent a cup of glass, wood, or any other non-conductor, and N S a small magnet, having a hole drilled at S, whereby it may be fixed by a short piece of silk S*c*′, to the copper wire *c*′ C, passing through the foot of the cup, and let mercury be poured into the latter till the needle floats nearly vertical. Conceive, also, Z *z*′ to be part of the conducting wire, descending from the zinc side of the battery, and slightly immersed in the quicksilver. If now the contact be made at C with the copper side of the battery, the magnet N S begins to rotate about the wire Z *z*′, passing towards the left hand of the observer. This rotation will be greater or less according to the power of the battery, and will continue while there is sufficient force in the latter to overcome the resistance of the quicksilver to the motion of the magnet. If the descending wire proceed from the copper side of the battery, the motion will take place in a contrary direction, that is, from left to right.

426. Or, if the contact remain the same, and the magnet inverted, then also the motion will be reversed; but if the contact and magnet be both reversed, the rotation will be the same as in the first instance. This highly curious and important experiment, which is due to Mr. Faraday of the Royal Institution, is immediately explained by the same hypothesis; according to which, the extremity N of the magnet is always acted upon by two forces, one being the galvanic force, which is tangential to the wire, and the other the tension of the silk S*c*′, in the direction of the needle. Let this latter be resolved into two forces, one vertical and the other horizontal, and we shall find the extremity N under the influence of two horizontal forces, one always central and the other tangential. The result of which must be a rotation of that point about the wire; and it will be made with the position and arrangement shown in the figure from right to left.

427. To exhibit the rotation of a galvanic wire about the magnet, let A B D E, fig. 16, be a cup or vessel of wood or glass, and N S a magnet passing tight through its foot; Z *z* a conducting wire descending from the zinc side of the battery, and rendered free to move by the chain connexion at *g*. Let mercury be poured into the vessel till the extremity of the wire is slightly

immersed in it. Then the contact being made at C (which, by means of the wire DC, communicates with the quicksilver) the wire $gz$ will immediately assume a rapid rotatory motion, much greater than in the former case, the resistance being very considerably diminished by the mode of suspension. The direction of the motion, according to the arrangement in the figure, being from left to right, to a person coinciding in position with the magnet. It may, however, be reversed by reversing the magnet, or by changing the contact, as in the preceding cases.

428. This experiment is also due to Mr. Faraday, and its explanation is the same as the last; for since when the magnet is free, it will, as we have seen, revolve about the wire from right to left, it follows that, when the magnet is fixed and the wire free, the latter will revolve in an opposite direction (the action and re-action between the wire and the magnet being reciprocal), which is still, however, towards the left of a person supposed now as coinciding in position with the magnet, and his head to the north.

429. The resistance being very inconsiderable in this experiment, it may be exhibited in a more simple manner. For instance, instead of piercing the foot of the cup, as in the figure referred to, it will be sufficient to use a tea-saucer, or any other shallow vessel, and to bring a strong magnet as near to it as possible under the table; when the motion will take place precisely in the same manner as above.

430. By this means also we may establish a most important fact, viz. that it is indifferent, as to the result of the experiment, what may be the position of the magnet; that is to say, if we keep the extremity of it as nearly as possible under the centre of the vessel, we may hold it either vertical or horizontal, or incline it in any angle, and at any azimuth, without greatly changing the rate of the rotation; it being always understood that the magnet should be of considerable length, in order that its other pole may not affect the motion of the wire.

431. The machine for the exhibition of these motions, according to Mr. Faraday's construction, is shown at fig. 1, plate III. ABCD is a stand of wood, EF a brass pillar, FG a fore arm or projecting piece of brass, through the extremity of which passes the wire LHK; at L there is a sort of ball and socket joint; the socket being in the upper part, and the ball fitting it, on the small wire $Lm$. Both the socket and ball are amalgamated, and a piece of silk fixed to the ball, or head of the wire, passes through a hole drilled in the wire LH, and by which the smaller wire is suspended, thereby preserving the contact, and leaving to the latter a perfect freedom of motion: $ab$ is a glass cup having a hole through its foot, into which is inserted a copper tube, soldered to a copper disc just the size of the bottom of the glass, and which disc is cemented to the foot of the latter.

432. The wire $Zz$ is also soldered to another copper disc, upon which the glass rests; and by which the contact is carried on from Z to the quicksilver in the cup, and thence to the wire $m$L; lastly, a small magnet $ns$ is inserted into the copper tube, passing through the stem of the glass above mentioned.

433. The foot of the cup $cd$ is pierced, and discs of copper applied as in the cup $ab$; but the wire passing through the foot is solid, and to it is fixed, by a short string, the small magnet $ns$, which is thus free to revolve about the descending wire HK; quicksilver, as in the preceding cases, being poured into the cup, till the wire HK is slightly immersed in it at K. The contact with the battery being now made at Z and C′, the motions will take place as described in the last two experiments; viz. that the magnet $ns$ in the one cup will revolve about the wire K, while the wire $Lm$ will at the same time be revolving about the other magnet $ns$.

434. If the cup $cd$ be placed where the cup $ab$ is represented, then the magnet and wire being both free, they will revolve about each other, and thus produce a pleasing variety in the experiment.

435. A section of this machine is shown at fig. 2.

436. Mr. Faraday also describes another apparatus, which requires a less galvanic action than the former to produce the rotation. This is shown at fig. 3; it consists of a piece of glass tube, the bottom part of which is closed by a cork, and through it is passed a small piece of soft iron wire, so as to project above and below the cork. A little mercury is then poured in, to form a channel between the iron wire and the glass tube. The upper orifice is also closed by a cork, through which a piece of platinum wire passes, being terminated within by a loop; another piece of wire hangs from this by a loop, and its lower end, which dips a very little way into the mercury, being amalgamated, it is preserved from adhering either to the iron wire or the glass. Things being thus arranged, a very minute galvanic power being applied by contact with the lower and upper end of the apparatus, and the pole of a strong magnet being applied to the external end of the lower iron wire, the moveable wire within begins rapidly to rotate round the temporary magnet thus formed; and which rotation may be inverted either by changing the contact or by inverting the magnet. Mr. Faraday states that this instrument is so sensible that a rotation has been produced in it by two plates, each only one inch square.

437. To exhibit the rotation of a magnet on its axis by the effect of a galvanic wire, let ABDE, fig. 4, represent a cup of glass or wood, NS a magnet, having at its lower extremity a fine steel point, inserted in the agate $a$; $bc$ is a thin slip of brass or ivory, having a hole through which the magnet passes freely, and by means of which it is kept perpendicular: at the upper extremity N of the magnet is a thin cylinder, as a piece of quill, forming a cup or reservoir $z$ to receive a small quantity of quicksilver; and into this is inserted the wire Z, amalgamated at its lower point; and $Cc$ is a stout wire passing through the side of the cup into the quicksilver. Then, the contact being made at C and Z, the magnet will begin to revolve on its axis, with a very astonishing velocity, and continue in motion while the power of the battery lasts.

438. This pleasing experiment is due to M.

Ampere, who employs only a piece of platinum attached to the magnet, to produce, by its superior gravity, a vertical position of the latter in the mercury; the upper wire being then inserted into the quicksilver in the cylinder *z*, and the other wire into the cup C, the motion is produced exactly as above described: the greatest freedom of motion is, however, given by the apparatus shown in the figure. The explanation of this rotation is very obvious according to the hypothesis we have adopted, for the tangential force of the wire, acting upon the magnetic particles on the surface of the magnet, must necessarily produce the rotation in question.

439. To exhibit the rotation of a galvanic wire on its axis by the action of a magnet, let N S, fig. 5, be a magnet, represented as broken in the figure, but which is fixed, in the experiment, in a foot, in order to keep it vertical, and let *a b c d* be a light hollow copper or brass cylinder, having a steel point passing downwards into the agate cup *f*, fixed to the upper end of the magnet, and let *e* be a small tube or quill fixed on the wire passing through the top of the cylinder, holding a little quicksilver, and receiving into it the descending conducting wire Z. A B is a piece of wood turned to fit on the cylindrical magnet N S, which has a hollow groove on its upper surface to receive a quantity of quicksilver, into which the lower edge of the cylinder *a d* is slightly immersed, the surface being covered with weak dilute nitric acid. A C is a wire passing into the quicksilver. It is obvious that thus (the contact being made at Z and C) the galvanic circuit is carried from Z through the cylinder *a b c d*, thence to the quicksilver, and hence again through the wire A E, to the other extremity of the battery, whereby the cylinder *a b c d* is made to become a part of the conducting wire; and it will be found to revolve on its axis with a great velocity, fully equal to that of the magnet in the last experiment; the direction of the motion, with the arrangement shown in the figure, being from left to right, to a person coinciding in position with the magnet.

440. To exhibit a quicksilver vortex by means of a galvanic wire and magnet, it is only necessary to take any shallow non-conducting vessel, and put into it a quantity of pure mercury, into which is to be inserted the conducting wires Z, C, proceeding respectively from the zinc and copper sides of the battery. And if now the north end of a strong magnet be brought under the vessel, the quicksilver round the wire C will begin to revolve about the same, forming a beautiful vortex; the direction of the motion being from left to right. If the magnet be removed under the other wire, the same kind of motion will be produced, but its direction will be reversed; and the same change of motion will take place, of course, in each case, by changing the end of the magnet.

441. The explanation here is precisely the same as in the last experiment; the moveable part of the conductor in this case owing its mobility to its fluid nature, whereas in the former it is due to the peculiar mode of suspension. This very elegant experiment was, as we have stated in another place, first made by Sir H. Davy.

442. To exhibit the rotation of the galvanic wire, independently of the galvanic battery, we must employ the apparatus exhibited in fig. 6, where A B C D is a small copper vessel about two inches and a half high, and the same in diameter; *a b c d* is another small cylinder of copper, of the same height, soldered to the former vessel at its lower end *d e*, a hole being left in the bottom of the former to receive it. The cylinder *a b c d* is therefore open, and will admit a cylindrical magnet to be passed up; and it will, at the same time, hold a quantity of dilute acid within the space A D, *d a b c*, B C: *z z'* is a zinc cylinder, very light, of rather less altitude than the copper one. To the cylinders *a b* and *z z'* are soldered two copper wires, as shown in the figure, the upper one having a steel point proceeding from E downwards, and resting in a small metal hole at F; and consequently the cylinder *z z'* will be free to move upon its point of suspension at F.

443. The apparatus being thus arranged, and the acid placed in the cell as above described, insert through the interior cylinder the north end of a strong cylindrical magnet, and balance the whole apparatus upon it, when immediately the zinc cylinder will begin to revolve with a greater or less velocity, according to the strength of the acid, the freedom of motion, and the power of the magnet. Mr. Barlow has frequently produced, with this simple apparatus, a motion, amounting to 120 rotations per minute. The only difference between this and the other rotations we have described is, that the galvanic power is here produced by the apparatus itself, instead of having recourse to the battery.

444. For it is obvious that the wire from Z Z' to E, may be considered as a conductor proceeding from the zinc; and the wire from *a b* to F, as one from the copper side of the battery; and consequently, the same effect is to be expected here as in the preceding cases. It is unnecessary to add, that, with the north end of the magnet upwards, the motion is from left to right, and the contrary with the magnet reversed. This experiment is due to M. Ampere.

445. A very pleasing addition has been made to this apparatus by Mr. J. Marsh. It consists in having a second point descending from F, which is made to rest in an agate cup, fixed on the top of the magnet, fig. 7, and upon which the whole machine is balanced, having a perfect freedom of motion; and, to preserve this balance, the magnet is placed vertically in a foot. The machine being now charged with acid, a compound motion takes place, the zinc cylinder revolving in one direction, and the copper vessel in another, producing thus a very pleasing effect; the latter, however, is by no means so rapid as the other, in consequence of the weight of the acid; and, in fact, that of the whole machine being supported on the lower point.

446. To show the effect of a horse-shoe magnet on a freely suspended galvanic wire, let Z *z*, fig. 8, denote a part of the galvanic wire, freely suspended by the chain connexion at *o*, proceeding from the zinc end of a battery, its lower extremity being amalgamated, and slightly immersed in a reservoir of pure mercury, having a

connexion at C with the other extremity of the battery. N S is a horse-shoe magnet, posited as shown in the figure.

447. The contact being now made at C and Z, the hanging part of the wire, $oz$, will be thrown out of the mercury into the position $o z'$; the contact being thus broken, it falls by its own gravity into the mercury; by which means, the contact being renewed, it is again projected, and so on with an extraordinary rapidity; and if the position of the magnet be reversed, or the contact be changed, the direction of the motion will be changed also, but the effect will be the same.

448. This singular motion may be still explained by the hypothesis that has been advanced; for the wire having a tendency to pass round the north end of the magnet to the right hand, and round the south end to the left hand, is urged by equal forces directly in a line with the open space of the magnet, the equality of the two forces preventing the rotatory motion about either, but both conspiring to give to the wire the rectilinear motion which has been described. This experiment is also due to Mr. J. Marsh.

449. If we wish to exhibit a wheel and axle rotation by means of a horse-shoe magnet, the machine represented in fig. 9 will produce this motion. A B is a rectangular piece of hard wood; C D an upright wooden pillar; D E a piece of stout brass or copper wire; and $ab$ a somewhat smaller wire, soldered upon it at E, on the lower side of which the wheel W, of thin copper, turns freely; $hf$ is a small reservoir for mercury, sunk in the wood; and $g\ i$ a narrow channel running into it. H H is a strong horse-shoe magnet. Mercury being now poured into the reservoir $fg$, till the tips of the wheel are slightly immersed in it, and the surface covered with weak dilute nitric acid, let the connexion with the battery be made at $i$ and D, and the wheel W will immediately begin to rotate with great velocity. If the contact be changed, or if the magnet be inverted, the motion of the wheel will be reversed; but, in general, the best effect is produced when the wheel revolves inwards. The suspension of the wheel is shown in fig. 10. This is a necessary consequence of the motion described in the last experiment, by which it was suggested, and is explained on the same principles.

450. The machine for exhibiting a compound wheel and axle rotation, with two horse-shoe magnets, is shown in fig. 11. A B C D is a rectangular piece of board, having two grooves about half an inch deep, cut in it parallel to its length. C $p$, Z $q$, are two wires, having cups for connexion at Z and C, and each passing into its respective groove, $ab$, $cd$, filled with mercury, into which are slightly immersed the points of the wheels W W'; these being fixed on an axle W W', and resting upon the two supports $mn$, $rs$, brought to a fine edge at $n$ and $s$, in order to reduce the friction as much as possible, and to give the greater freedom of motion. N S are two horse-shoe magnets, posited as in the figure, with the like poles interior and exterior of the wheels.

451. The apparatus being thus prepared, and the contact made at Z and C, the wheels will begin to rotate, and in a very short time will acquire a velocity exceeding, very considerably, any of the motions hitherto described.

452. It is unnecessary to say, that by changing the contact, or by inverting the magnets, the direction of the rotation will be also changed. The usual precaution of covering the surface of the mercury with weak dilute nitric acid, will increase the rapidity of rotation; but it is not actually necessary in this case.

453. To exhibit the terrestrial directive quality of a galvanic wire, let A B, fig. 12, represent a piece of wood fixed to any convenient support, through which pass the two wires G, E, and where they remain fixed. At their upper and lower extremities are soldered the small metal cups, $a$, $b$, $c$, $d$. D H I K, &c., is a part of the conducting wire, bent into the form shown in the figure, having small steel points soldered upon it at $c$ and $d$. These points are inserted into the cups $c$, $d$, the upper one only resting on the base of its cup, the other being merely brought into contact with $d$, by a little quicksilver placed in it for that purpose, by which means the rectangle has a great freedom of motion given to it, the only solid contact being on the point $c$. Mercury is also poured into the other cups, for the sake of a more perfect and certain communication than that afforded by the mere juxta-position of the wires.

454. The apparatus being thus prepared, the two wires proceeding from the copper and zinc sides of the battery, are inserted into the cups $a$, $b$, and thus the connexion is established; first by means of the wire G with the cup $c$, thence by means of the contact of the points with the cup and mercury; it is carried forward from $c$ through the rectangle, to the cup $d$, whence it proceeds to the cup $a$.

455. We have already seen that of this connecting wire, the part from $c$ to $d$ has a perfect freedom of motion upon the point at $c$, and will therefore obey any exciting force. This force, in the experiment in question, is the magnetic influence of the earth; and in consequence of which the rectangle, immediately the contact is made, places its plane perpendicular to the plane of the magnetic meridian; and to which position it will always return, after a few vibrations, if it be drawn out of it by the hand or otherwise.

456. This arrangement of the moveable conductors is perfectly consistent with our hypothesis, as is obvious without any farther illustration than what has been given in several preceding experiments.

457. A differently formed wire, and a more simple mode of suspension, is shown in fig. 13. Here a brass or copper wire, A C, rests at its bent end A, in a cup containing a little mercury, and is very moveable in azimuth round this point. The other end passes through the centre of a circular piece of pasteboard, and then forms spiral turnings in the plane of this circular piece. The wire is attached by thread or silk to the pasteboard disc; and at the point B it turns and descends till its extremity reaches the quicksilver in the cup D. The communication being now made at A and D with the battery, the spiral will immediately arrange itself, as in the last

case, in a plane perpendicular to the magnetic meridian. This experiment is originally due to M. Ampere, but the mode of suspension described is that of professor Van den Boss.

458. A needle, upon a different construction, also due to M. Ampere, is shown in fig. 14.

459. The directive quality of the galvanic wire has been since exhibited in a variety of ways, much more simple than that above described, of which we shall only state the following:—

460. M. de la Rive's apparatus consists of a small galvanic combination attached to a cork; the plate of zinc is nearly half an inch wide, and extends about one and a half, or two inches, below its cork, its upper end passing through the same; the slip of copper is of equal width to the zinc, but passes round it, being thus opposed to both its surfaces, as in Dr. Wollaston's construction: its upper end also appears through the cork. A piece of copper wire, covered with silk thread, is coiled five or six times, and tied together, so as to form a ring about an inch in diameter; and the ends of the wire are connected by solder, one with the zinc, and the other with the copper slip above the cork. See fig. 15.

461. When this small apparatus is placed in water, slightly acidulated with sulphuric or nitric acid, the ring becomes highly magnetic, and will arrange itself in a plane perpendicular to the magnetic meridian, or it will at least indicate a tendency to take up that position; but the escape of the bubbles, arising from the decomposition of the water, prevents it from preserving a fixed direction.

462. Its magnetic qualities, however, are more obviously shown by bringing to it a strong magnet. Mr. Barlow used a cylindrical one, about three quarters in diameter, and eighteen inches in length. This being applied at the distance of several inches, the ring was immediately attracted or repelled accordingly, as one or the other of the poles of the magnet was presented, or accordingly as one or the other side of the wire was opposed to the latter. When the result of the application is attraction, the cork will advance towards the extremity of the magnet; and if the latter be held horizontally, and in a line with the centre of the former, this will continue to advance till the pole of the magnet is within the ring, and then proceed with considerable velocity till it reaches the middle of the magnet, where it remains perfectly stationary. If now the magnet be withdrawn, and changed end for end, and re-introduced into the ring, the latter will go off from the magnet, turn itself round when quite free from it; again advance, and settle itself as before in the centre.

463. This very simple apparatus, which may be made at the expense of about a shilling, throws great light upon the nature of the electro-magnetic action, and proves most satisfactorily, that notwithstanding the intimate relation between the electro-magnetic, and simple magnetic fluids, they are not identical; for no possible arrangement of simple magnets can be made that would lead one of them beyond the pole of another, to find its state of equilibrium in the middle of the latter. At the same time all the above facts will be found perfectly consistent with the hypothesis that has been advanced; for it will be seen, when the wire and cork are in equilibrium, as above stated, that an observer will have the north end of the magnet to his left hand, and the south to his right, at equal distances; and acting therefore with equal and opposite powers; consequently the wire itself ought to be in equilibrio, and, when disturbed from, it will have a tendency to regain it, and hence be subject to all the conditions and motions that have been described.

464. As the current of electricity, produced by a Voltaic battery when passing through a metallic conductor, powerfully affects a magnet, tending to make its poles pass round the wire, and in this way moving considerable masses of matter, it was supposed that a re-action would be exerted upon the electric current capable of producing some visible effect; and the expectation being, for various reasons, that the approximation of a pole of a powerful magnet would diminish the current of electricity, the following experiment was made:—The poles of a battery of from two to thirty four-inch plates were connected by a metallic wire, formed in one part into a helix, with numerous convolutions, whilst into the circuit, at another part, was introduced a delicate galvanometer. The magnet was then put, in various positions, and to different extents, into the helix, and the needle of the galvanometer noticed; no effect, however, upon it could be observed. The circuit was made very long, short, of wires of different metals and different diameters down to extreme fineness, but the results were always the same. Magnets more and less powerful were used, some so strong as to bend the wire in its endeavours to pass round it. Hence it appears, that however powerful the action of an electric current may be upon a magnet, the latter has no tendency, by re-action, to diminish or increase the intensity of the former.

465. M Prechtl has a very curious experimental illustration of the effects of a spiral wire. He coils round a glass tube or wooden cylinder, steel-wire covering the surface as with a continuous sheath. To one end of this cylindric spiral, he applies the south or north pole of a magnet, and draws it along the cylinder in a straight line, parallel to the axis. In this way a magnet is formed, which possesses the following properties:—

(*a*) Along its whole length, it has on one side the north, and on the opposite side, the south pole.

(*b*) These transversal magnetisms are in every point of the length of the wire-cylinder, equally strong.

(*c*) Both of its ends exhibit on the contrary no particular polarity, and they have no other magnetism than that which belongs to every individual point of the whole length. Thus the transversal magnet is in the same condition as the conjunctive wire of the Voltaic column.

(*d*) If we hold this transversal magnet over a magnetic needle in the declination-plane, it repels exactly like the conjunctive wire, the north pole of the needle to the right or to the left, ac-

cording as the effective north pole of its transversal magnetism lies to the left or to the right hand; and with greater or less force, according to the strength of its magnetism, even to 90°.

(*e*) If we draw the one pole of a magnet along this transversal-magnet, in a spiral direction, the wire becomes magnetised longitudinally; the transversal magnetism disappears, the two poles are found at the two extremities, and it now resembles an ordinary magnetised steel wire. The longitudinal and transversal magnetisms are not compatible with each other, in their full exhibition.

466. Besides this transversal magnetism, with single polarity, magnets may be easily made, possessing several transversal magnetisms. Take four magnetic bars, about a quarter of an inch thick; provide a small disc of wood, with an aperture of about an inch diameter in its centre, and four grooves, cut into one face of the disc, leading from the circumference, inwards: in these grooves the magnetic bars are to be fixed, with their narrow edge outwards, and their ends projecting into the aperture. Let a north pole alternate with a south pole in the circle, so that the ends of the bars right opposite to each other may be homogeneous; and adjust the whole, so that they may touch the circumference of a steel wire-coil, about half an inch diameter. We then draw this spiral wire through the opening, and between the four magnets, taking care that the cylindric coil does not revolve on its axis, but that the direction of each individual magnetic pole remains in the same plane with the axis; for otherwise the wire would acquire the longitudinal magnetism. Instead of the wire-coil, we may take a massive cylinder of steel. This will acquire, when treated in the same way, the compound transversal magnetism, without its extremities having a stronger magnetism than each of its cross sections. These transversal magnets with manifold polarities, have all the above enumerated properties of the single transversal magnets, but their phenomena are still more in unison with those of the electrical conjunctive wire; for, under this manifold polarised magnet, the deviation of the needle is the reverse of that above the magnet.

467. In the following manner we may produce a section of a manifold polarised transversal magnet in a larger rod, and with a proportionally greater number of poles. We take a ring of steel wire, from four to six inches diameter, and furnish it with as many poles as we can apply to its circumference. Lay the ring flat on a table, and apply to its outer edge the two poles of a horse-shoe magnet, that are as near each other as possible; then remove the magnet and apply it in succession all around, at distances equal to the width of its own poles. In this way it is easy to induce on a steel ring, of about five or six inches diameter, from twenty to thirty opposite poles.

468. This steel ring, which represents a section of the manifold polarised transversal magnet, exhibits, relatively to the greater extension and smaller number of the existing magnetisms, the phenomena which a conjunctive wire presents. In every part of it the magnetic needle, with its north end above, stands to the right hand; below it, to the left; and inversely. M. Prechtl thinks that these direct results leave no further doubt concerning the magnetical condition of the conjunctive wire.

469. Although success had attended the experiments made to magnetise steel needles and bars by ordinary electricity when in motion, yet every attempt to occasion the deviation of the magnetic needle by a current from the machine had failed, until M. Colladon instituted his experiments. Conceiving that the quantities of electricity operated with had been too small, he used a battery of thirty jars, containing 4000 square inches of surface for the previous accumulation of the electricity, and operated with a galvanometer constructed on Nobili's principle, having 100 revolutions of wire. The wire was covered with a double thickness of silk, and the instrument placed in a room away from that containing the battery. Two copper wires covered with silk, and suspended on silk cord, connected it with the electrical apparatus. A very fine point was soldered on to each of these wires, which were then named the extremities of the galvanometer.

470. The battery was charged: one galvanometer extremity was connected with the outer coating, and the other approached towards a ball in connexion with the inner coating. When at four or five centimetres' distance, (an inch and a half or two inches) the needle deviated; when at less than half that distance, the deviation was 23°, and, gradually diminishing, continued for five seconds. The direction of the deviation accorded with the course of the electricity. Every repetition of the experiment gave the same result, and when the points brought to the battery were changed, or the charge of the battery itself was altered, the direction of the deviation corresponded with it. The quantity of deviation varying with the distance of the points was often 40°; and the return of the magnetic needle to its original position, upon the cessation of the current, was in every instance ascertained.

471. On making experiments with a Nairn's machine, and also with a plate machine, no accumulative apparatus being used, deviations of the needle, amounting to 3° or 4°, were obtained in dry weather.

472. It was thus demonstrated that the electrical machine could, like the Voltaic pile, produce a current competent to the deviation of the needle, and that the electricity accumulated in a given time in a battery, or even in a conductor, was a finite portion of that which circulated in the same time in a closed electro-motive circuit. To establish this comparison in a more definite manner, a wire of platina was soldered to the two extremities of the galvanometer, one of the junctions heated, and the other cooled; at 125°, C. (268° F.) the needle of the galvanometer deviated 45°, the same quantity which had been produced by the battery. Hence it appears that the galvanometer may, in certain cases, be a very useful indication of the quantities of ordinary electricity.

473. The insulation of the different turns of the galvanometer wire, appearing to be an im-

portant point, M. Colladon prepared an instrument, in which the wire was covered with two folds of silk, made 500 turns round the box, and had each separated from the others by oiled silk. With this instrument the effects were nearly tenfold what they were before, and as, in the former case, the deviation of the needle, by the current from a machine, was only 3° or 4°, now it amounted to much larger quantities. When the point was at the distance of—

| | | | | |
|---|---|---|---|---|
| 1 decimetre (3·937 inches) | | the deviation was | | 18° |
| 2 | ditto | ditto | ditto | 10 |
| 4 | ditto | ditto | ditto | 5½ |
| 8 | ditto | ditto | ditto | 3 |
| 1 metre (39·371 inches) | | | ditto | 2; |

so that it was rendered sensible at the distance of a metre from the conductor.

474. It should be remarked that the withdrawing action of a point is sensibly proportional to its distance from the conductor. This is constantly the case with a cylinder machine, but seemed to be interfered with in a plate machine by the presence of four cushions. Experiments, instituted to illustrate this point, proved the correctness of this conclusion. When the motion of the cylinder machine was regular, the deviation remained constant as long as the experiment was continued.

Operating with the battery, and slowly approaching the point, a constant deviation of 30° was obtained for sixty-five seconds. A jar, containing only two half-square feet of surface, deviated the needle 32°.

475. The ratios which these experiments establish between the action of currents produced by electrical machines, and those of a pile or a thermo-electric arrangement, afford the means of appreciating the absolute velocity with which the electricity moves in a closed electro-motive apparatus, when we know their electro-motive force, or the tension which may be produced by the contact of two metals, and the friction of cushions. In fact, in electrical machines, this velocity of circulation is determined by the motion of the glass plate, by which the electricity is transported to the conductors with a known velocity. If the tension of this electricity is ten thousand times stronger than the tension of a pair of Voltaic plates, having the same surface as the cushion, and nevertheless the effects produced by the two currents on a galvanometer are the same, the velocity of circulation of the electricity from the Voltaic arrangement would be evidently ten thousand times greater than that of the rubbed part of the plate; for it is an acknowledged opinion, that the deviation of the magnetic needle is proportional to the quantity of electricity which passes in the current.

476. Comparative experiments, made with piles and thermo-electric circuits, prove that the conductibility of metallic wires is not in the inverse ratio of their length. When the electromotive force is small, a metallic circuit of moderate length is sufficient to stop the electric current almost entirely. The intensity of the current rapidly increases as the length of the circuit is diminished to a certain limit, dependent on the energy of the electro-motive force.

477. M. Colladon observes also, that although bad conductors, as pure water for example, cannot be made part of a Voltaic circuit without stopping the motions of the galvanometer; yet a layer of air, of more than a metre in thickness, does not always prevent this kind of action, and that the results depend upon the energy of the electro-motive force; so that this becomes an important element, not to be neglected in experiments on the conductibility of bodies.

478. Taking advantage of some stormy weather, M. Colladon was enabled to obtain deviations of the magnetic needle by currents of atmospheric electricity, and has shown that the instrument may become a very precise and useful indication of the state of this agent in the atmosphere. A metallic point being raised on the observatory of the college of France, and connected with the galvanometer, whilst the other extremity of the instrument wire was communicated with the stem of a lightning-rod, deviations were obtained of 32°, 34°, and 37°. The direction of the needle indicated negative electricity, and by dismounting the apparatus, and using an electrometer, this was found to be the case. On another occasion the deviation was from 10° to 22°, and, during the twenty minutes that the instrument was observed, the direction of the current changed two or three times. On another occasion the deviation amounted to 87°. These results were obtained with the first and least sensible galvanometer.

479. These experiments prove that the galvanometer may be very useful in researches on atmospheric electricity. If it should be demonstrated that electricity contributes to the formation of hail, this instrument would be the only one which could indicate in a precise manner the quantities of electricity withdrawn by points more or less acute and elevated, and communicating more or less with the soil.

480. M. Nobili's galvanometer is a curious instrument. Its construction is founded upon the fact discovered by Oersted, the deviation of a magnetic needle by a wire conveying a current of electricity; and, as in most other instruments of this kind, the wire is passed several times round the frame, within which the needle is suspended, that the effect may be proportionally increased. It differs, however, from all made before it, in the use of two needles instead of one: these are equal in size, parallel to each other, magnetised in opposite directions, and fixed on a straw, so that the contrary ends of the two needles point in the same direction. Their distance from each other on the straw is regulated by the construction of the frame with its covering wire, in and about which they are to move. The frame of M. Nobili is twenty-two lines long, twelve wide and six high. The wire is of copper covered with silk, it is one-fifth of a line in thickness, from twenty-nine to thirty-feet long. It makes seventy-two revolutions about the frame. The needles are twenty-two lines long, three lines wide, a quarter of a line thick, and they are placed on the straw five lines apart from each other. An aperture is made in the tissue formed by the turns of the wire on the upper surface of the galvanometer, by thrusting them from the middle towards each side; the lower

needle on the straw is introduced through this aperture into the interior, in consequence of which the upper needle remains a little above the upper surface of the wire. The aperture is retained open to a certain extent, to allow freedom of motion to the needles and straw, these being suspended in the usual way from the upper extremity of the straw. The graduated circle, on which the deviation is measured, is placed over the wire on the upper surface of the frame, having an aperture in its centre for the free passage of the needle and straw. The upper needle is the index, the lower being visible only from the sides of the instrument.

481. The sensibility of this instrument depends upon the addition of the upper needle. Being magnetised in an opposite direction to the lower one, it almost entirely neutralises the influence of terrestrial magnetism, leaving only so much of directive power as shall induce the whole arrangement to return to a constant position when uninfluenced by electrical currents, and yet combining with the lower needle, to cause deflexion when an electrical current is passing through the wire.

482. As an illustration of the delicacy of the instrument M. Nobili observes, that it is well known if Sebeck's combination of antimony and bismuth be attached to a common galvanometer, and the point of junction be cooled, only a very slight effect is observed on the instrument; whilst, if attached to the new galvanometer, the same influence is sufficient to make the needles revolve several times. If a piece of iron wire, five or six inches long, be used to connect the extremities of the copper wire of the instrument, by twisting the ends together, and one of the points of contact be warmed by touching it with the hand, the needle will move from 0°, and in the first oscillation extend to 90°. Even the mere approximation of the hand to the junction of the metals will produce a deviation of 20°.

483. It is necessary for the delicacy of the instrument that the needles used be magnetised as nearly as possible to the same degree, and two indications have been observed as useful in pointing out when this is the case; the first is the position taken up by the plane of the needles, when left to the earth's influence, this should not be in the plane of the magnetic meridian, but more or less inclined to it; the second is the manner in which the system oscillates about its line of equilibrium. These oscillations should be very slow compared with those of a common needle.

484. In consequence of the situation of the graduated circle above, and not within the frame, the folds of the wire may be brought much nearer to each other than in the common instrument, this renders it more compact, and, from the vicinity of the needle within to the wire, also more powerful. When fixing the graduation the zero should be placed so as to accord with the position of the needles, when left to the earth's influence; this will not be towards the true magnetic north, but will not be far from it, and will always be constant.

485. M. Nobili then offers a very curious illustration of the powers of the instrument:—'It is known,' he says, 'that water usually retains itself at a lower temperature than the ambient air, the difference being sometimes 2°, and resulting from the evaporation of the liquid. If a bar of bismuth be made to join the two extremities of the galvanometer wire, and one of the points of junction be plunged into a cup of water, the needle will immediately deviate several degrees proving that the instrument is capable of measuring the small degree of refrigeration produced by the evaporation of the liquid. I have actually submitted one of my galvanometers for fifteen days to an experiment of this kind, the deviation was about 15° in the morning and evening, but more considerable in the course of the day. This first attempt has made me suppose that the galvanometer might become, in the hands of an attentive and skilful philosopher, a kind of *atmidometer*. If by means of a single couple of different metals, bismuth and copper, a deviation of 15° has been obtained, a much greater one would be produced by employing several pairs, conveniently immersed in the same vessel of water; and, perhaps, one might succeed by increasing the scale of observation, in ascertaining more exactly the diurnal rate of evaporation. I propose, also, to ascertain the effect of a current of air, excited by any means over the surface of the water used in the experiment; it would, without doubt, augment the evaporation, and, by increasing the difference between the temperature of the air and the water, increase the effect on the instrument.

486. The theory of electro-magnetism remains to be illustrated. The phenomena developed were, at first view, not a little perplexing; and it was not till after repeated investigation, that, in 1820, any tangible view of the matter was furnished. The conducting wire was found to exert a magnetic force, not in a direction parallel to the wire itself, nor even in any plane passing through that direction, but in one that was perpendicular to it; and which, if circles were described in this latter plane, having the point at which it intersects the wire for their common centre, would have the direction of tangents to those circles. The following is another mode of conceiving the same thing. Imagine a cylinder of any diameter to envelope the wire,—the wire itself being in the axis; and conceive the surface of the cylinder to be covered on all sides with an infinite number of short lines touching the surface at different points, and situated transversely, that is, at right angles to its length. Suppose these lines to represent magnets, with the northern polarity of each turned in one invariable direction, as we follow them round the cylinder. Then will these imaginary magnets indicate the direction and nature of magnetic forces, which emanate from the fire as long as the stream of Voltaic electricity is passing through it. The particular direction of the transverse, or, as it has been termed, tangential magnetic force will of course depend on that of the electric current in the wire, and may easily be traced in all cases by the recollection of the following fact. Supposing the wire to be in a vertical position—in which case the planes of the tangential forces will be horizontal—and supposing the stream of positive electricity to be

descending along the wire, which of course implies that the negative electricity is ascending, then that polarity which exists in the end of the magnetic needle, which naturally turns to the north, will be impelled round the wire in the circumference of a circle in a direction similar to the motion of the hands of a watch; that is, from the north to the east, and then to the south and west. The south pole of a magnet will of course be impelled in the contrary direction. A magnetic body in the vicinity of the wire will, by the influence of this force, tend to assume a position, shown in fig. 16, similar to one of the tangential lines we have been describing as placed on the cylinder. But further, the tendency of the electric current in the wire is to induce magnetism in soft iron or other bodies capable of receiving it; and the magnetism so reduced has the precise direction already indicated as that which a bar previously magnetised would assume by the influence of the wire. This direction is shown in the figure, where N and S denote respectively the north and south poles of steel bars, situated transversely with respect to a vertical conducting wire, in which the current of positive electricity is descending, as indicated by the arrows.

487. Most of the facts which have been brought to light by Oersted are the immediate consequences of the above general law. Mr. Barlow's enunciation of this law is as follows: he states 'that every particle of the galvanic fluid in the conducting wire acts on every particle of the magnetic fluid in a magnetised needle, with a force varying inversely as the square of the distance; but that the action of the particles of the fluid in the wire is neither to attract nor to repel either poles of a magnetic particle, but a tangential force, which has a tendency to place the poles of either fluid at right angles to those of the other; whereby a magnetic particle, supposing it under the influence of the wire only, would always place itself at right angles to the line let fall from it perpendicular to the wire, and to the direction of the wire itself at that point.'

488. The transverse, or tangential action, which we have been describing is one of so extraordinary a nature, that it can be assimilated to no other principle in nature, of which we have any knowledge. It is not, therefore, surprising that it eluded the observation of former enquirers, although in the keenness of research, they almost stumbled upon the discovery. The fact which occurred to Beccaria, of the production of transverse magnetism in an iron bar, by the electric discharge of a battery, had, in fact, pointed out the precise direction of this inductive force; and the hint, if pursued, would have infallibly led to the discovery which Oersted made fifty years afterwards. It is curious that a circumstance extremely similar is on record, with regard to the observation which conducted Galvani to the discovery of the science which bears his name; namely, the convulsive movements of the muscles of frogs, on taking sparks from a neighbouring prime conductor, charged with electricity. The very same fact had been noticed by Du Verney, about a century before, as appears from a memoir in the History of the French Academy of Sciences, for 1700; but was deemed of no importance.

489. The relation which this new magnetic power bears to the electrical, was also very singular and enigmatical. Considered as a magnet the conducting wire acted differently, according to the side to which magnetic bodies were presented to it. What was attracted by the one side was repelled by the other; and, if the power were conceived to be derived from the impulse of a fluid, that fluid must be circulating perpetually round the wire in a kind of vortex, of which the wire is the axis. The consequence of such a vertiginous motion, as Dr. Wollaston has termed it, in the magnetic fluid, would necessarily, under certain circumstances, produce rotatory motions in the parts of certain combinations of magnets and of wires. The suggestion thus thrown out by Dr. Wollaston was soon after realized, by Mr. Faraday's discovery of the rotatory movements which had been predicted, and which we have already pretty fully described. By employing mercury as part of the Voltaic circuit, and placed so as to allow of perfect freedom of motion in the conducting wire, or in the magnet, according to the nature of the experiment, and so as to obtain the action of one pole only, Mr. Faraday succeded in effecting a variety of rotations, both in the magnet and the wire, in conformity with the law above stated. If the positive electric current be descending along the wire, the north pole of a magnet in its vicinity will revolve round it in the direction indicated by the arrows. As action and re-action are equal and contrary, the wire was seen to revolve round a fixed magnet, in a direction contrary to that in which the magnet would have moved, if the wire had been stationary; but, since these motions are to be estimated on opposite sides of a common centre, the direction in the circumference will remain the same. Thus, as a north pole revolves round a descending positive electric current in the direction of the hands of a watch, a wire in which a similar current is descending, will revolve in the same circular direction round a north pole placed in the centre of its motion.

490. The experiments of Mr. Faraday and professor Barlow, confirmed and extended as they have been by Barlow, Biot, and others, appeared to have conducted us to the most general fact belonging to the science; namely, the tendency to a transverse rotatory motion in the magnetic and electric fluids, when acting freely on each other. This fundamental principle once admitted, all the phenomena that had hitherto been discovered appeared to be easily explicable, and most of them were the immediate and necessary consequence of that principle. There was, indeed, one particular fact, for the discovery of which we are indebted to M. Ampere, to which it was less directly applicable, and which might not, perhaps, have been deduced as one of its results. This distinguished philosopher observed, that when two conducting wires were so arranged as that one or both of them were allowed a certain freedom of motion, they either attracted or repelled each other, according as the electric current which they transmitted was moving in the same or in opposite directions in the two wires.

If, for example, two wires, which are transmitting currents of electricity, be situated within a certain distance, and parallel to each other; and if we suppose the currents of positive electricity to be passing from left to right in both the wires, they will manifest an attraction for each other. The same tendency of attraction will also appear when the positive currents are both moving in the contrary direction, that is, from right to left. But if the current in one wire is moving in a direction opposite to that of the current in the other wire, in that case a repulsive action will take place between the two wires. These were found to be constant and invariable effects of the transmission of electricity along conductors; and they were manifested equally, whether the two currents were obtained from separate Voltaic batteries, or were only two portions of the same current in different parts of its course.

491. To understand Ampére's theory, let us conceive a slender cylinder of iron intersected by an infinite number of planes, perpendicular to the axis, so as to divide it into as many circular discs, successively applied to each other, as represented in the engraving, at fig. 17: let us now imagine that, in consequence of some unknown action among the particles composing these circles, a current of electricity is perpetually circulating in their circumferences, as if they had composed a Voltaic circuit. Let us suppose the direction of these currents to be the same throughout the whole series of circles: the cylinder thus constituted may be considered as a magnetic filament; that extremity in which, when uppermost, the current of positive electricity is moving in a direction contrary to the hands of a watch, being the one which has the northern polarity, that is to say, which will, when suspended as in a compass-needle, point to the north. It is of course to be understood that the current of negative electricity revolves in the opposite direction. A magnet, then, is supposed to consist of an assemblage of similarly-constituted filaments; and, if these postulates be once granted, all the phenomena of magnetism will flow from them as corollaries; the magnetic power will be resolved into the electrical, and be henceforth erased from the list of original physical powers.

492. The facts belonging to the science of electro-magnetism may be classed under five heads:—the first relating to the reciprocal actions of two electric currents when traversing a conducting substance: the second, to the mutual action occurring between electric currents and magnets: the third, to the magnetic action of the earth on electrical currents: the fourth, comprising the actions of magnets on each other: the fifth, the action of the earth on magnets. These two last divisions of the subject constituted what was properly the province of the science of magnetism; the three former having sprung up in consequence of the discovery of Oersted, and being of an intermediate character, had received the name of electro-magnetism. Ampére proposes to comprehend them all under the title of electro-dynamics.

493. Setting out, then, from the primitive fact, that parallel currents attract one another when their directions are the same, and repel one another when opposite, we have to study the law of modification which these forces undergo when the currents deviate from strict parallelism, and are inclined to one another at various angles, and in different planes. It is evident that the whole action of the currents must be the combined result of the actions of all their parts; and that in order to obtain the former, in every possible case, with mathematical precision, it is necessary to ascertain the simple law which governs the action of those elementary portions.

494. It is evident, in the first place, that the action will be in proportion to the intensities of the currents from which that action is derived; and it has been also determined, that the quantity of each action in each element, follows the same law as that of gravitation—namely, that it is inversely proportional to the square of the distance. The action, estimated in the direction of the line drawn from the one elementary portion of electric current to the other, and which, for the sake of convenience, we shall term the line of junction, will be diminished by any obliquity in the direction of either of the currents—in the proportion of the radius to the sine of the angle which such direction forms with the line of junction. If, again, we consider the effects of a current, of which the direction deviates from the plane that passes through the line of junction, and through the direction of the other current, and is situated in another plane, also passing through the line of junction, we shall find that, from being at a maximum when these two planes coincided, it will be reduced to the proportion of the cosine of the angle they form between them. Taking all these considerations, then, into account, and combining them in one formula, we obtain the following, in which $a$ and $b$ denote the respective intensities of the two elementary portions of each current; $d$ their absolute distance from each other, measured of course on the line of junction; $\alpha$, $\beta$, the angles which their respective directions make with the line of junction, and $\gamma$ the angle between two planes, each passing through the direction of the respective current and the line of junction. Then the action of the two currents on each other, estimated in the direction of the line of junction, being expressed by A,

$$A = \frac{ab}{d^2} (\sin. \alpha. \sin. \beta. \cos. \gamma.)$$

495. In the course of this investigation, Ampére found reason to conclude that the formula thus obtained was still only an approximation to the true law; for portions of the same, or o different currents, that were moving at very oblique angles, or even in the same continued line, were observed to exert a certain degree of repulsion on each other: he therefore introduced another term in the formula; and, as he was at first unable to ascertain the amount of its influence, prefixed to it the co-efficient $k$, the value of which was left for future determination. The whole formula will then stand thus:—

$$A = \frac{ab}{d^2} (\sin. \alpha. \sin. \beta. \cos. \gamma. + k. \cos. \alpha. \cos. \beta.$$

496. Ampère at first regarded the value of $k$ as exceedingly small, and thought it might safely be neglected. Subsequent researches have led him to conclude that it was equal to $-\frac{1}{2}$, so that the whole of that term has a negative value when the cosines of the two angles are themselves positive

497. The forces of electro-dynamical action, determined by the law above stated, are subject to the same laws of composition and resolution as all other mechanical forces, and afford, therefore, equal facilities for mathematical investigation. Many consequences important to the theory of particular facts are deducible from this consideration. Thus the action of a small portion of conducting wire, bent into any number of flexures and contorted forms, provided they do not extend to any great space, upon a distant current of electricity, will be equivalent to that of a similar wire proceeding in a straight course between the two extreme points of the contorted wire.

498. Another corollary deducible from the general law is, that the total action of a conducting wire of infinite length upon any portion of an electric current, moving in a direction parallel to the wire, is in the simple inverse ratio of the shortest distance intervening between the two currents—that is, of the line drawn from one to the other, which is perpendicular to both. This consequence had been already deduced by Laplace, and was verified by direct experiment by Biot, as well as by Ampère.

499. Setting out from the simplest case, where a simple attractive or repulsive power is manifested, namely, that in which two currents are rectilineal, and in parallel directions, and in which the action is at its maximum in point of degree, we proceed to consider the variations which a change of inclination will produce. Let us first suppose one of the rectilinear currents, or wire which conveys it, to be inclined, as is shown at fig. 18, at a certain angle, and in a plane which does not pass through the other wire, or channel in which the other current is moving. In this case, a compound force, or at least one that may be resolved into two forces, is called into action. Let us suppose a line $m\,n$, fig. 18, drawn between the points, in each wire, which are the nearest to each other; a line which will, of course, be perpendicular to both the wires, and which may be called the line of junction: the points $m, n$, where this line meets the wires, will divide each wire respectively into two portions. Those portions of the wires, as $a$ and $b$, or $c$ and $d$, in which the currents are both moving, either towards those points or from them, will be attracted towards each other,—an action which will at first tend to turn them on the line of junction $mn$, as an axis, in planes perpendicular to that axis, so as to diminish the angle which they form, and to bring them into the parallel positions indicated by the dotted lines; and will also tend to make the two wires approximate. The former portion of this force, which produces a rotatory action, may be termed a directive force; the latter, which tends to the approach of the wires in the direction of the line of junction, may be termed the approximate force. This last force commences when the two wires are at right angles, and attains its maximum when they are brought by the directive force into a parallel position. When the corresponding portions of the wires, on the contrary, form an obtuse angle, the approximative force is negative, and is so in the greatest degree when the wires are parallel, with their current, moving in opposite directions.

500. This action will be considerably modified if, instead of supposing the two currents to be of equal length, and crossing one another at the line of junction, we take only a very limited portion of a rectilineal current, situated wholly on one side of the other current, which is itself of indefinite length; and we may now, for the sake of greater simplicity, assume them to be both in the same plane. If we analyse the forces which act on each side, and on each part of the limited portion of the current, the one set being attractive and the other repulsive, we shall find that the resultant is a force which will impel it in a direction perpendicular to itself, in the plane common to the currents, and so as to preserve its parallelism; and this will happen, whatever be the angle of inclination of the less current to the greater. Indeed we might show by experiment the direction in which the shorter wires will tend to move by the action of the current in the lower wire, supposed to be of indefinite length. The direction of this progressive tendency will be determined by that of the currents. When they are parallel to each other, they tend to approach or to separate, according as the direction of the currents is similar or dissimilar. When at right angles to each other, and the positive current in the shorter wire is receding from the longer wire, the shorter wire will be urged forwards in the same direction as the positive current is moving in the longer wire; and, vice versâ, it will be urged in the opposite direction when the current of positive electricity is moving towards the longer wire. Such then would be its motion were it free to move in all directions; but, if its motion be limited, in that plane, to a movement of rotation round one of its extremities, the same force will produce its continual revolution, with a uniformly accelerated velocity round this axis; because the force itself is independent of the angle of inclination of the currents, and is, therefore, uniformly exerted during the whole period of its revolution. It is to be observed, however, that the two cases we have here supposed, in which the effec of a straight current of indefinite length can be limited to a small portion of another current on one side only, are such as are not easily realised in practice. The difficulty lies in disposing of the remaining portions of the current, so that they shall not interfere with the effects intended to be produced. The only mode of obtaining this object is to provide for their subdivision and branching off in different directions, at the end which is nearest to the current whose action we are studying; so that these different portions shall act in opposite ways, and thus neutralise each other's effects. This object may be accomplished most conveniently and effectually by allowing the ends of the smaller portions of

wire to dip in mercury; which will not only carry off the stream of electricity in various directions, but also allow of perfect freedom of motion.

501. Let us now investigate the action of currents moving in the circumference of a circle, which may be examined by means of a conducting wire bent into such a form, that its extremities come very near each other, but are prevented from touching by being covered with silk, or other insulating substances. The force acting on such a wire, while it is transmitting electricity by the influence of a rectilineal current in the vicinity, will tend to bring it into such a position, as that its plane shall coincide with that of the rectilineal current, and so that the direction of the currents in the adjacent portions may be the same. In this position, these adjacent portions attract each other, while a repulsion is exerted between the straight current and that in the remoter part of the circle, which moves in the opposite direction. These two forces are, therefore, opposed to each other; but the attractive force prevails, on account of the greater vicinity of the attracting than of the repelling portions. That portion of the original force which made the plane turn upon itself, so as to bring it into parallelism with the straight current, must be regarded as the directive force. It is here composed of two forces, the one attractive, the other repulsive, but which, acting on opposite sides of the axis of rotation, concur in their effect. Thus while the approximative force is the difference of the two forces, the directive force is equal to their sum.

502. It will be easily understood, that forces of a similar kind are the result of the action of the circular current on the straight wire; and that the latter is urged to assume a position in the same plane with the former, and so that the adjacent currents may be in similar directions.

503. The action of a circular current upon a small portion of a straight current at right angles, or otherwise inclined to the plane of the former, and lying wholly on one side of it, will be somewhat modified. If the direction of the straight current, when prolonged, pass near the centre, the forces which act upon it will be nearly balanced, and no re-action will result; if it be near to the circumference the action of the adjacent portion will predominate, and we shall obtain results analogous to those which we have traced with regard to straight wires. Revolving motions will result either in the straight wire or in the circular one, according to their positions, and according to the direction of the fixed points which may limit their movements. The direction of the motion is determined by the circumstances of the approach or recession of the current to or from the same point, as we have before explained.

504. Having considered the action of a circular on a rectilineal current, we may now study the reciprocal action of two circular currents. When the centre of the one lies in the plane of the other circle, a directive force will operate, tending to bring its whole circumference into that plane, and to assume a new position; and when, in this position, the resultant of all the forces which are in operation will be an attraction or a repulsion, according as the currents in the adjacent portions of the circumferences are moving in the same, or in opposite directions.

505. If the two circular currents be situated opposite to each other, so that the centre of the one be in a line perpendicular to the plane of the other, and passing through its centre, similar phenomena will take place with respect to the directive and approximative forces; which will produce, in the first place, a tendency to parallelism, and then either attraction or repulsion. For each position of the centres intermediate to the two former, we shall find a particular position of equilibrium in planes inclined at a certain angle, whose intersection is exterior to the circles themselves. This position of equilibrium is determinate, and excludes the possibility of any continued rotatory or revolving motion.

506. It is an important preliminary to the study of Ampère's theory to obtain correct ideas of the action of the two circular currents upon one another, because such currents are supposed, in his hypothesis, to be the elements of all magnetic action. This magnetic action may be regarded as the resultant of the forces exerted by every part of the circular currents; and as constituting two forces emanating from its centre, and being of an opposite species on each side of the plane of the circle. If we suppose the circle to occupy a vertical plane passing nearly through the eye of the observer, placed without the circle, and the current of positive electricity to be passing downwards on the side next to the spectator, and upwards on the remoter side, then the force exerted on the side to the right of the plane, considered as a magnetic force, will correspond to the northern polarity, or to a polarity belonging to that end of the compass which turns to the north. The force extending to the left, will, of course, correspond to the southern or opposite polarity. When two circular currents are brought together on the sides where similar polarities reside, they repel each other, because the two currents are then moving in opposite directions in each; but, when the dissimilar polarities are presented to each other, attraction takes place, because the currents are then similarly directed.

507. The intensity of all these forces is much increased when the powers of several circles are combined, which may be obtained by bending the conducting wire so as to compose a spiral; the successive coils of which will conspire together in producing the respective polarities on each side: spirals thus constituted act exactly as magnets whose poles might be supposed to be situated in the centre of each disc.

508. But the imitation of magnetic bodies is rendered still more complete, when the turns of the wire are made, not in the same plane, but on the surface of a cylinder, so as to form a helix instead of a spiral. If the wire, after having formed a helix, be bent back so as to return in a straight course in the interior of the cylinder, with the usual precautions against contact, we obtain a very perfect accordance with the theory already examined.

509. We come now to the subject of terrestrial magnetism. If we assume that the action of the solar rays on successive parts of the torrid zone, from east to west, produces currents of positive electricity in that direction, and which may be regarded as collectively circulating in what may be called the magnetic equator; attended, as they must always be, by counter-currents of negative electricity in the same equator, but in the opposite direction; and also that these currents have the same properties and modes of action with all other electrical currents,—then there must result, as a necessary consequence, a twofold polarity, apparently belonging to the earth, and directed to the poles of this magnetic equator.

510. It is to be observed, that as that polarity, which is situated near the north pole of the earth, results from a current moving in a direction similar to that of the hands of a watch, it will have the properties of a southern polarity, in the sense in which we have invariably used the term; that is, it will attract the north pole of a magnet, and repel the south pole; while actions the reverse of this will take place in the southern hemisphere. It is unnecessary to remark, how exactly this theory accords with all the known facts relative to the action of the earth on magnets. The directive power which acts on magnets on the surface of the earth, is the result, not of any real influence proceeding from that part of the earth to which their poles point, but of the action of the currents at the magnetic equator, and the tendency of the currents in the magnet itself to turn it, so that they shall attain the position of equilibrium we have already adverted to, in considering the mutual action of two circular currents. This position is precisely the plane which is perpendicular to the line of magnetic direction; that is, to the axis of the dipping needle: for as the electric currents in the needle are at right angles to its axis, it follows that when they arrange themselves in conformity with the equatorial currents of the earth, that are circulating east and west, that axis and the whole needle will point to the north and south —as we find they actually do.

511. The nature of this influence is more clearly discernible when it is exhibited in its simplest form, on a single circular current, which, as we have seen, may be regarded as the element of a magnet. A conducting-wire bent into the form of a circle, when free to move, always assumes, by the electro-magnetic action of the earth, a position in a plane descending to the south, intersecting the horizon in a line passing east and west, and inclined to it at an angle which is the complement to the dip; that is, in a plane which is perpendicular to the magnetic meridian. Its northern and southern polarities are equally real with that of a magnetic needle; but appertain to an imaginary axis passing through the centre of the circle and perpendicular to its plane. The direction of the currents on its south side, or that nearest the equator, is similar to those in the earth's equator—that is, from east to west (the positive current being always understood as defining the direction). All these circumstances are sufficiently illustrated in the theory we have been endeavouring to explain, and of which we shall furnish experimental data in referring to the apparatus contrived by Mr. Barlow, and employed in the theatre of the London Institution.

512. The same phenomena are observed, if the course of a moveable wire be that of a parallelogram; or, indeed, any plane figure which returns into itself, as well as if it were a circle. By varying these forms, we are enabled to observe and distinguish the effects of the earth's influence on wires which are parallel to the direction of the dip, and on such as are at right angles.

513. The action of the earth on spiral conducting wires is precisely similar in kind to that of single circles, but it is more powerful in degree. Helices are, in like manner, found to obey the terrestrial influence, just as magnets do when placed in similar circumstances as to freedom of motion, provided the electrical currents which they convey are of sufficient intensity. Continued progressive, or even rotatory motion may be obtained by the same influence, in conductors whose motions are limited to certain planes, either in parallel directions, or round an axis. So that, in fact, every experiment that has been tried, and a great variety has been devised by the ingenuity of numerous experimentalists, has served but to confirm the correctness of Ampère's views of the theory of magnetism. It is easy to distinguish whether the motion of any part of a Voltaic circuit is the effect of the influence of the earth, or merely of the other portions of the same circuit, by reversing the communications with the ends of the pile or battery employed: in the former case, the direction of the motion is immediately reversed by this change; and in the latter case, the action continues the same as before.

514. Ampère is far from supposing that the successive action of the solar rays on the equatorial regions of the earth is the sole cause of the electric currents that circulate in them. Internal changes, taking place in the earth itself, must also concur in producing them; for it would otherwise be impossible to account for the observed variations in their effects. The diurnal variations may, however, fairly enough be attributed to the alternate changes of temperature occurring in different parts of the torrid, and even of the temperate zones.

515. The phenomena of magnetic induction, whether effected by currents of electricity passing through a conducting body, or by a magnet in which such currents are assumed to exist, are also in perfect conformity with this hypothesis. A conducting wire tends to the determination of currents in the same direction as those which it conveys itself, in all the magnetisable bodies in its vicinity: these currents continue to circulate with more or less permanency, after the removal of the current which originally determined them. In soft iron they soon disappear: in steel they continue to maintain themselves, and give rise to permanent magnets. The polarities thus induced will have transverse directions with respect to that of the current to which they owe their

origin, for the reasons we have already so fully explained.

516. Numerous facts have induced Ampère to conclude, that the circulation of electric currents peculiar to magnets takes place round each particle of the magnetic body; he has also adopted the opinion that these currents pre-existed, in the bodies susceptible of magnetism, before this property was imparted to them; but, as they were moving in every variety of direction, they neutralised each other, and could produce no external effect. It is only when a determinate direction has been given to them, either by another magnet or by a Voltaic current, that they become capable of exerting any magnetic action.

517. By a very curious experiment, Ampère has proved, that a powerful electric current has a tendency to excite similar currents in neighbouring bodies, not generally susceptible of magnetism. A copper wire of considerable length was rolled round a cylinder, so as to form a coil, all the turns of which were separated from each other by silk riband. Within this spiral coil a ring of brass was freely suspended by a fine metallic thread, passing through a small glass tube, which was placed between the threads of the copper coil. The circumference of the ring, in every part, was thus brought very near to the copper wire, through which a powerful Voltaic current was made to pass. Under these circumstances the brass wire was attracted or repelled by a magnet, in the same way as it would have been had it formed part of the same Voltaic circuit. The action, indeed, was but feeble, and Ampère, in his first trials, failed in his endeavours to render it sensible; but, on persevering in the attempt, his success, at last, was complete and unequivocal.

518. A simple circular current, or what will act still more powerfully, a spiral coil, when presented to a magnet exhibits phenomena precisely analogous to those afforded by the ends of magnets; acting as north poles on one side, and as south poles on the other. If the currents in these spirals be reversed, the polarities on each side are in consequence immediately reversed; what was before a north, now becomes a south pole; and vice versâ.

519. But the simple circular conducting wire or ring exhibits, in consequence of the vacant space in its centre, phenomena which neither the spiral coil, of which the turns occupy the whole disc of the circle, nor any magnetised iron can produce. M. De la Rive contrived, upon this principle, a very pretty and instructive experiment, which is noticed in another part of this article. A floating conducting ring being placed so as to encircle a magnet, but in such a way as that the currents in each did not accord, was repelled along the magnet till it reached its end; when it spontaneously turned half round, and was then attracted by the magnet, again encircled it, and proceeded to settle itself round the middle of its length, where it remained in equilibrio.

520. A still more perfect accordance with magnetic phenomena is presented by the heliacal arrangements which we have denominated Voltaic magnets. These possess regular poles at both ends; the one being north, the other south: which poles are immediately changed into the opposite kinds, by merely reversing the course of the current. They obey the action of magnets which are presented to them, are attracted and repelled, and assume determinate positions with respect to the magnet, just as if they were ordinary magnets: of which, indeed, they possess all the essential properties, and for which they may be substituted in almost every form of experiment.

521. The phenomena of revolving motions, effected either in magnets or in wires, by their mutual action, as first discovered by Mr. Faraday, and as afterwards extended by Ampère, Barlow, Savary and others, and which have been regarded by most philosophers as indicative of the rotatory tendency being an ultimate fact, will be found, on attentive examination, to be not only in strict accordance with, but to be direct consequences of Ampère's theory. Instead of constituting objections to that theory, as was at one time supposed, they have proved, in fact, to be amongst the strongest confirmations of its truth. It would extend this article to too great a length were we to engage in the detail of the circumstances of each experiment, so as to follow all the particular applications of the theory, and trace their agreement with the observed results; but the general principles on which they are to be accounted for have already been sufficiently explained. It is also to be remarked, that Ampère ascertained, by suitable variation in the experiments, that these rotatory movements, although strictly deducible from his own theory of the constitution of magnets, where the action of the portion of conducting wire was alone taken into account, were generally, in a much greater degree, the effect of electric currents taking place in the mercury, into which the extremities of the wire were immersed, and the re-action of which on the wire produced a considerable repelling force. He found it, indeed, as impracticable in mechanism, as it was impossible in theory, to produce rotation without employing fluid conductors in some part of the Voltaic circuit.

522. To take one of the simplest cases of electro-magnetic action, let us suppose a vertical conducting wire, in which the positive current is descending, presented to a magnetic bar suspended by its centre, so as to move freely in a horizontal plane, and which has assumed its usual position in the magnetic meridian by the influence of the earth. In this position, all the currents contained in the magnet are ascending on its western, and descending on its eastern side. The former will therefore be repelled, and the latter attracted by the wire, and the magnet will so arrange itself that the middle of its attracting side shall be opposite to the wire.

523. When two magnets, on the other hand, are presented to each other, end to end, it will depend upon the direction of the currents being similar or dissimilar at the adjacent ends, whether attraction or repulsion will take place; the former happens when the north and south poles are opposite to each other: the latter when simi-

lar poles front each other. The first case may be illustrated by two watches laid the one above the other, so that the dial of the one may be in contact with the back of the other; the hands will then, in both watches, be moving in the same direction. The second case is represented by their being laid face to face, when it will be seen that the motion of the hands are now in opposite directions.

524. But the attractive or repulsive forces are not merely produced by currents at the ends of the mangets; they are the result of the action of all the currents from one end to the other of each magnet. We must regard the total action as composed of the attraction or repulsion of one whole side of the one to one whole side of the other; and of a similar attraction or repulsion between the two other sides: while the contrary action is excited between those respective sides which may be differently grouped. Thus, calling the east and west sides of a magnet the sides which face those points, when its axis is in its natural position in the magnetic meridian, the east side of the one will attract the east side of the other, and repel the west side: the west side will, in like manner, attract the west and repel the east. The tendency of this action is to bring the two eastern sides parallel, and as near to each other as possible: when this position has been attained, the north pole of each magnet will be adjoining to the south pole of the other, and the attractive action will be at its maximum. The same must be understood, mutatis mutandis, of the repulsive action, which is greatest when the east side of the one is parallel and adjoining to the west side of the other; in which case the two poles of the same name in each magnet are adjoining to each other.

525. The attentive consideration of these combinations of forces will explain a difficulty which at first might be apt to startle us. When the north end of one magnet is directly opposed to the south end of another, the adjacent currents run in similar directions, and there is, therefore no difficulty in understanding how attraction takes place: but if the one magnet be moved a little to one side, and brought in a parallel direction, till the two adjacent ends have just past one another, we then find that such a coincidence of adjacent currents no longer takes place: on the contrary the eastern side of the one, where the current is descending, is close to the western side of the other, having an ascending current. Repulsion therefore, as it would seem, should now take the place of attraction: whereas we find that, under these circumstances, the two poles still exert a powerful attraction. The reason, however, will appear when the actions of all the other currents, besides those that are immediately adjacent, are taken into account. It will then be found that the repelling positions belonging to the two magnets are, in consequence of the great obliquity of their actions, much less powerful than the attractive portions, which act at a greater angle.

526. Mr. Buxton has published a new theory of electro-magnetism in a work of Mr. Partington's, to which it may be advisable briefly to call the reader's attention. He says, 'I have at all times been particularly averse to the basis upon which the present theory of electro-magnetism is founded, where there is supposed to exist a strong analogy, if not a comple identity, between the electric and magnetic fluids; and also to the many unnatural modifications which have been resorted to in order to support the above position. I allude to the various routes which the electric fluid has been supposed to take in its transmission through a conductor connected with the two poles of a galvanic battery, in order to account for the deflection of a magnetised needle exposed to its influence, while it is a well-known fact that electricity invariably takes the most direct and shortest route in its transmission through any conducting substance.

527. 'Naturam expellas furcâ tamen usque recurret,' says Horace; and in this instance it is verified. For even with the assistance of these assumptions, and many others, which are not only irreconcileable with the known and established laws of nature, but even incongruous to each other, we are unable to account for many of the most interesting phenomena of the science. It would be wrong to reject any hypothesis without giving some grounds of objection, and I shall therefore endeavour to show, that though these two properties may, in an unqualified sense, be made to agree and to possess similar attributes, yet neither of these argues a physical identity, or even analogy. It is true, they may be made to agree, but this only in a bare definition, inasmuch as they may both be defined to be properties of natural bodies; but this must not be taken as a general definition, as it would lead to the presumption of a co-existence of these two properties in all bodies, whilst, in fact, the metallic bodies are those only wherein they are found in combination: the non-metallic bodies, though evidently possessing the electric principle, seem destitute of the magnetic. Hence we draw our primary distinction, that electricity is a general physical property of all bodies, and that magnetism is a particular property of metals.

528. 'If electricity and magnetism were identical, their phenomena should be similar, and should be exerted under similar circumstances.

529. 'Electricity is capable of exerting attractions and repulsions, and magnetism possesses the same attributes; but this parity exists merely in the unqualified ideas of mere attraction and repulsion, without adverting to the particular circumstances under which these phenomena are made sensible, or the particular objects upon which their influence is exerted.

530. 'Electricity appears to attract all bodies, but repels itself. Thus, when a body in its natural state of electricity is brought within the influence of another body which contains a quantity of the electric principle redundant to its natural capacity, the first body will abstract the fluid from the second, and be attracted by it until they both become similarly electrised, when they will be repelled.

531. 'From these premises, we draw the conclusion that the attractive and repulsive qualities of electricity are dependent upon the different relative proportions of this principle in each containing body, with respect to its capacity, and to the

different relative proportions contained in both bodies with respect to one another.

532. 'But in magnetism these qualities are exerted under a complete dissimilarity of circumstances; for, on two magnetic bodies being brought within the sphere of each other's action, we find that the different parts of the several bodies act differently upon each other; hence, that part of the magnetised body which we denominate the north pole, attracts that part of a similar body denominated the south pole, and, è converso, any two of these similar and corresponding parts in different bodies repel each other. From this we may infer, that the attractions and repulsions exerted by magnetic bodies are dependent upon different modes of action, being exerted in different situations in similar bodies, and not from any difference in the relative proportions of the magnetic principle existing in the different bodies, as is the case in electricity.

533. 'The dissimilar modes of action employed by electricity and magnetism, in exerting their attractive and repulsive qualities, may be elucidated by the following experiment: If a piece of steel, highly magnetised, be brought within a short distance of another piece of steel in its natural state, the latter will be powerfully attracted; and, until being drawn into close contact with the former, they will both exhibit a similarity of magnetic phenomena, and remain in that situation until disturbed by some extrinsic agent. Whereas, in order that these properties of attraction and repulsion exerted by magnetism should coincide in their modes of action with electricity, a mutual attraction should at first take place between the two bodies until both become equally magnetic, when they should be mutually repelled.

534. 'So far I have merely mentioned those properties of electricity which, from a too hasty observation, might appear also to obtain generally in magnetism; but I might adduce many properties in each of these which are not found in the other. This might, however, lead to a disquisition which would form an octavo volume, and I must therefore refrain from trespassing on your valuable pages.

535. 'Though the renouncement of the principle of identity of electricity and magnetism is a sufficient denial of the present theory, it will be found that, even with the admission of this principle, it would be incapable of accounting for many of its most brilliant phenomena. Among these are the interesting experiments of the attraction of two parallel galvanised wires, when the route of the electric fluid is similar; and their repulsion, when the electric fluid in each passes in a contrary direction. Another peculiarity which theorists have been unable either to reconcile or smother, is the fact, that if a piece of soft iron be placed in a tube of glass, and hermetically sealed, the whole being enclosed in a spiral conducting wire, on the galvanic stream passing through the spiral, the enclosed piece of iron will become strongly magnetic; if we admit this as the immediate effect of electricity, we must deny the impermeability of glass by the electric fluid, and with it the theory of the Leyden jar, and in fact endanger the whole science of electricity.

536. 'The admission of an analogy existing between electricity and magnetism, seems the effect of a too superficial observation and hasty conclusion, and the notion seems first to have arisen from the circumstance that lightning has been known sometimes to destroy the polarity of magnetised needles, at others to have magnetised pieces of steel which had not before any sensible magnetic properties. After the observation of these facts, and when the identity of lightning and electricity was afterwards established, it was presumed that common electricity would necessarily produce the same effects: this is found to be the case, and steel may be magnetised either by the Voltaic pile, or by the electric machine.

537. 'But, though electricity is thus capable of exciting magnetism in iron and other metals, still this property is not confined to electricity, for the same effect is produced by filing, drilling, twisting, and several other mechanical means. Electricity ought, therefore, merely to be considered as one of the various means which nature employs to excite the latent magnetic properties of metals.

538. 'Having so far premised, I shall now endeavour to show that the phenomena of electro-magnetism are merely some of the most simple operations of nature, and that they involve no difficulties but what are easily explained by her most simple laws.

539. 'If we admit of magnetism being an essential property of metals, as no magnetic phenomena are sensible to our observation, except under particular circumstances, we must necessarily infer that this property exists in a latent state, which must arise from the natural disposition of the parts of the metal being unsuitable to the circulation of the magnetic fluid; a necessary precedent to any magnetic phenomena.

540. 'That some metals are more easily magnetised than others is a well-known fact, and this frequently obtains in similar metals which have been differently operated upon; this must be ascribed to the above cause, viz.:—to the different organisation of different metals. Thus the latent magnetic principle in steel may not only be brought into action by means of electricity, but the same may be effected by a blow, twisting, &c., and by being rubbed upon an already excited magnet; whilst, to excite the latent magnetic principle inherent in gold, silver, brass, and other metals, the transmission of an electric stream across the metal seems invariably necessary: this, by disturbing the mutual cohesion of the parts of the metal, and by opening a free passage for its own circulation, at the same time, effects a similar arrangement for the circulation of the heretofore latent magnetic fluid.

541. 'If the electric force thus employed be but small, and the parts of the metal through which it has been transmitted not sufficiently removed without their mutual sphere of attraction, the magnetism excited will be but temporary; for, immediately upon the discontinuance of the electric stream, the parts of the metal by their natural attraction will resume their original arrangement, and the magnetic principle will again become quiescent. If, however, the elec-

tric stream, transmitted through the metal be sufficiently strong to effect a total alteration of the relative situation of its parts, the circulation of the magnetic stream will remain constant. However, the permanence of the circulation of the magnetic stream does not seem so much to depend upon the intensity of the electric stream, as to its direction, with respect to the internal structure of the metal through which it has been transmitted.

542. 'Under the impression that all metals contained the magnetic principle in some degree, and also that the conducting wire, connected with the two sides of a battery, is actually magnetic during the transmission of the electric fluid, as is demonstrated by several indubitable experiments, I was led to suppose, that the deflection of a magnetic needle, and the other phenomena of electro-magnetism, were not the immediate effects of electricity, but of the temporary magnetism excited in the conducting wire, during the transmission of the electric fluid.

543. 'With this view, I undertook a series of experiments with different conductors of galvanism (avoiding the metals as being capable of magnetic excitation), supposing that as these non-metallic conductors were incapable of exerting magnetic influence, they would produce no disturbance in the needle during their transmission of the electric fluid; and these expectations were very satisfactorily realised; for on attaching any of these conductors to the poles of the battery, and presenting the needle, not the least sensible deflection was produced; but, on removing these, and substituting metallic conductors, a deflection of 90° immediately ensued.

544. 'In applying this position to electro-magnetism, it will not be necessary to recapitulate the experiments which have not only appeared in most of the journals of science, but have also appeared compiled in a volume. Neither will it be necessary to apply it minutely to any of the experiments, as from its simplicity the experimenter may, by substituting artificial magnets upon a wire, instead of exciting its inherent magnetism by means of the transmission of the electric fluid, perform several of the most pleasing experiments; and this would obtain universally, were he capable of adjusting his magnets with as much precision as is effected by electricity.

545. Before quitting this part of our subject, in which every care has been used to give to each individual experimenter his due proportion of praise, it may be proper to state that electro-magnetism is less indebted to Sir Humphrey Davy than is generally supposed, as will be seen by reference to a note from that distinguished individual to the Editor. He says "you have over-rated what I have done in the science. M. Oersted is the parent, and the very little I have done was a consequence of his original discovery." It must however be borne in mind that Sir Humphrey communicated much valuable information to the Royal Society on the subject, and that most of Mr. Faraday's Apparatus resulted from previous hints furnished by the illustrious President of that Society.

546. When two electrified spheres are made gradually to approach each other, and when there does not exist between the species and the quantities of electricity which they possess, the particular relation which would be established by their contact, the thickness of the electric stratum at the points nearest each other, on the two surfaces, becomes greater and greater, and increases indefinitely as their distance diminishes. It is the same with the pressure exerted by the electricity against the mass of air intercepted between the two spheres; since the pressure, as we have mentioned above, is always proportional to the square of the thickness of the electric strata. It must at last then overcome the resistance of the air, and the fluid, in escaping under the form of a spark or otherwise, must pass, previous to the contact, from the one surface to the other. The fluid thus accumulated, before the spark takes place, is of a different nature, and of nearly equal intensity on each of the spheres. If they are electrified, the one vitreously and the other resinously, it is vitreous in the first and resinous in the second; but when they are both electrified in the same manner, vitreously for example, there arises a decomposition of the combined electricity upon the sphere which contains less of the vitreous fluid than it would have in the case of contact; the resinous electricity, resulting from this decomposition, flows towards the point where the spark is preparing, and, on the contrary, the other sphere, which contains more vitreous electricity than it would have after the contact, remains vitreous over its whole extent.

547. The phenomena are no more the same after the two spheres have been brought in contact together, and are then removed, however little, from each other. The ratio which then exists between the total quantities of electricity with which they are charged, causes to disappear in the expression of the thickness, the term which before became infinitely great for a distance infinitely small, and no spark takes place. The electricity of the points nearest each other upon the two spheres is then very feeble, for very small distances, according to a law which calculation determines, and its intensity is nearly the same on both spheres; but, when they are unequal, this electricity is vitreous on the one, resinous on the other; and it is always upon the smallest that it becomes of a nature contrary to the total electricity, which is conformable to the observations related above.

548. In general, all the varieties of these phenomena depend on the relation which we establish between the radii of the two spheres, and also between the quantities of electricity with which they are charged. We may even determine these proportions in such a manner, that, at a certain distance, the thickness of the electric stratum on the small sphere may be almost constant, so that this sphere may remain near the other, almost as if it were not exposed to any action, not from the weakness of the electricity on the other sphere, but in consequence of a sort of equilibrium which is then established between

its action upon the smallest, and the re-action of this upon itself. In this case, the electricity diffused over the large sphere is vitreous in certain parts, resinous in others, and its thickness in different points presents very considerable variations. M. Poisson has determined the proportions of volume and of electric charge necessary to produce these phenomena; and in this respect, as we have formerly observed, his analysis has anticipated the observations.

549. To complete the case of two electrified spheres, placed in presence of each other, M. Poisson has calculated the changes which the greater or less distance produces on the state of the points most distant from those where the contact takes place. In this respect, he has found, that, in proportion as the two spheres approach each other, the thicknesses of the electric stratum in these points tend more and more towards the values which they would have at the instant of contact. As they arrive at this limit, however, but very slowly, it hence follows, that even at very small distances, they differ yet much from what they would be, if the contact or the spark actually took place. Hence we conclude also, that the spark, when it takes place at a sensible distance, changes suddenly the distribution of the electricity over the whole extent of the two surfaces, from the point where it is produced, even to that which is diametrically opposite. This re-action is easily verified by experiment: we have only to fix, at certain distances from each other, a long and insulated conductor, couples of linen threads, with pith-balls suspended to them, and to communicate to this conductor a certain quantity of electricity, by which the threads may be made to diverge; if we then draw successively, several sparks by the contact of an insulated sphere, whose volume is not too small, all the threads will be observed to be disturbed, and shaken in a manner by each explosion, in whatever part of the conductor it is produced.

550. For the particular case in which the two electrified spheres are removed to a great distance from each other, in relation to the radius of any one of them, M. Poisson has discovered formulæ, which express in a very simple manner the thickness of the electric stratum, in any point of their surfaces. We shall here state these formulæ as they enable us to explain distinctly why conducting bodies, when they are electrified, seem to attract or repel each other, although from the manner in which electricity is distributed among them, and from its mobility in their interior, we cannot suppose that these phenomena indicate any sensible affinity which it has for their substance. Let $r, r'$, represent the radii of the two spheres; call $e, e'$, the thicknesses of the strata which the quantities of electricity they possess would form upon their surfaces if they were left to themselves, and exempt from all external influence; call $a$ the distance of their centres, and place them so far from each other that the radius $r'$ of one of them be very small compared with $a$, and with $a-r$. Lastly, let $u, u'$, denote the angles formed with the distance $a$, by the radii drawn from the centre of each sphere to any point on their surfaces, then the thicknesses E, E′, of the electric stratum in these points will be expressed approximately by the following formulæ:—

$$E = e + \frac{e' r'^2}{a r} - \frac{e' r'^2 (a^2 - r^2)}{r (a^2 - 2 a r \cos. u + r^2)}$$

$$E' = e' - \frac{3 e r^2}{a^2} \cos. u' + \frac{5 e r^2 r'}{2 a^3} (1 - 3 \cos.^2 u')$$

551. Here, as in the experiments of Coulomb, the angles $u, u'$, are reckoned from the points A and $a$, in which the surfaces of the two spheres would touch each other, if we brought them to the point of contact. The difference of symmetry in these expressions is owing to this, that the approximation from which they arise supposes the radius $r'$ of the second, very small compared with the distance $a-r$, which separates its centre from the surface of the other.

552. If it is required, for example, from these formulæ to determine the state of an insulated, but not electrified sphere, which we present to the influence of another sphere charged with a certain quantity of electricity, we have only to suppose $e'$ nothing in the equation of the second sphere, and it will then become

$$E' = \frac{-3 e r^2}{a^2}\left[\cos. u' + (3 \cos.^2 u' - 1)\frac{5 r}{6 a}\right]$$

553. At the point $a$, on the line A$a$, between the two centres, the angle $u'$ is nothing. In this point then we have

$$\cos. u = 1 ; \text{ and } E' = -\frac{3 e r^2}{a^2}\left(1 + \frac{5 r'}{3 a}\right)$$

554. The thickness E′, then, has always a contrary sign to that of $e$, that is to say, that the electricity on this point, in the sphere of which the radius is $r'$, is of a nature contrary to that which covers the sphere of which the radius is $r$.

555. At the point $d$, diametrically opposite to the preceding, the angle $u'$ is equal to 180°, which gives

$$\cos. u' = -1 ; \text{ and } E' = + \frac{3 e r'^2}{a^2}\left(1 - \frac{5 r'}{3 a}\right)$$

556. This value of E′ has always the same sign with that of $e$; for the factor $\frac{5 r'}{3 a}$ is a fraction far smaller than unity, since the distance $a$ is supposed very great, compared with the radius $r'$; then the electric stratum will be in this point of the same nature as upon the other sphere.

557. Thus we see arising out of the theory the important result which we have until now only established by experiment, but while a sphere c, not electrified, is placed in presence of another sphere C, electrified vitreously, for example, the combined electricities of $c$ are partly decomposed; the resinous electricity that results flowing towards the part of $c$ which is nearest to C, and the vitreous electricity towards the part which is farthest from it.

558. The thicknesses of the stratum in these two points are to each other in the ratio of

$$1 + \frac{5 r'}{3 a} \text{ to } 1 - \frac{5 r'}{3 a};$$

they are nearly equal, then, since $a$ is supposed very great in relation to $r'$.

559. Hence it may be conceived that there must be upon the sphere $c$ a series of points, in which the thickness of the electric stratum is

nothing, and which form a curve of separation between the two fluids. The locus of these points will be found by putting the general expression of the thickness E′ equal to zero, which gives the condition

$$0 = \cos. u' + (3\cos.^2 u' - 1)\frac{5r'}{6a}.$$

560. If the distance $a$ were altogether infinite, compared with the radius $r'$, the second member of this equation would be reduced to $\cos. u'$; consequently, this cosine would be 0, which would give $u' = 90°$. The line of separation of the two fluids would then be the circumference of the great circle, of which the plane is perpendicular to the line of the centres.

561. But if $a$ is not infinite, it is at least very great relatively to $r'$. Thus, the factor $\frac{5r'}{6a}$ will still be a very small fraction, and the true value of $\cos. u'$ will be equally so. We may, therefore, in calculating, neglect the product of $\frac{5r'}{6a}$ by $\cos.^2 u'$, compared with the product of this same quantity by unity. With this modification the equation resolves itself and gives

$$\text{Cos. } u' = \frac{5r'}{6a}$$

In this case the line of separation of the two fluids is still a circle whose plane is perpendicular to the line of the centres; but the distance of this plane from the centre of the sphere, in the place of being nothing, is equal to $r' \cos. u'$ or $\frac{5r'^2}{6a}$, this distance being taken from $c$ to $a$, towards the electrified sphere C.

562. In considering only the degree of the equation which determines generally $\cos. u'$, there would seem to be two values of this cosine which would satisfy the conditions of our problem; but it will clearly appear, that one of those roots should necessarily be greater than unity, and, consequently, will not have here any real application, as it would correspond to an arc $u'$, which is imaginary.

563. When we now consider how various, how delicate, and how detached from each other, are the phenomena this theory embraces; with what exactness, also, it represents them, and follows, in a manner, all the windings of experiment, we must be convinced that it is one of the best established in physics, and that it bestows on the real existence of the two electric fluids the highest degree of probability, if not an absolute certainty. But what is not less valuable for science, it teaches us to fix, by exact definitions, the true meaning which we must attach to certain elements of the electrical phenomena, which are too often vaguely enunciated, or even confounded, with others; although the knowledge of each of them, individually, is indispensable to form a correct and general idea of the phenomena.

564. The first of these elements is the *species*, vitreous or resinous, of the electricity which exists at the surface of an electrified body, and at every point of this surface. This is determined by touching it with the proof plane, and presenting this to the needle of the electroscope, already charged with a known species of electricity.

565. The second element is the *quantity* of this electricity accumulated on every point, or, what comes to the same thing, *the thickness of the electric stratum.* This we still measure by touching the body with the proof plane, and communicating the electricity acquired by this contact to the fixed ball of the electric balance; the moveable one having been previously charged with electricity of the same nature. The force of torsion necessary to balance the electric reaction communicated by the plane to the fixed ball, is at equal distances proportional to the quantity of electricity which it possesses, or, what is the same thing, to the thickness of the electric stratum on the element of the surface which it has touched.

566. The third element which it is of importance to consider in the phenomena, is the *attractive or repulsive action* exerted by each element of the electric stratum upon a particle of the fluid situated at its exterior surface or beyond this surface. This attraction or repulsion is directly proportional to the thickness of the electric stratum on the superficial element which attracts or repels, and is inversely proportional to the square of the distance which separates this element from the point attracted or repelled.

567. In fine, the last element to be considered, and which is a consequence of the preceding ones, is the *pressure* which the electricity exerts against the external air in each point of the surface of the electrified body. The intensity of this pressure is proportional to the square of the thickness of the electric stratum.

568. By adhering strictly to these denominations, there will be no risk of falling into error from vague considerations; and if we also keep in mind the development of electricity by influence at a distance, we shall then find no difficulty in explaining all the electric phenomena.

569. To place this truth in its full light, we shall apply it to some general phenomena which, viewed in this manner, can be conceived with perfect clearness, but which, otherwise, do not admit but of vague and embarrassed explications. These phenomena consist in the motions which electrified bodies assume, or tend to assume, when they are placed in presence of each other, and in which they appear as if they really acted upon each other by attraction or by repulsion. But it is extremely difficult to conceive the cause of these movements, when we consider that, according to the experiments, the attraction and repulsion are only exerted between the electric principles themselves, without the material substance of the body, provided it be a conductor, having any influence on their distribution or their displacement. We cannot hence admit, that the particles of the electric principles, whatever they may be, really attract or repel the material particles of the bodies. It is absolutely necessary, therefore, that the attractive and repulsive actions of these principles, whatever they are, be transmitted indirectly to the material bodies, by some mechanism which it is of extreme importance to discover, as it is the true

key to these phenomena. But we shall see that this mechanism consists in the re-action produced by the resistance which the air and non-conducting bodies in general oppose to the passage of electricity.

570. For the sake of greater simplicity, we may first confine ourselves to the consideration of two electrified spheres A and B; the one A fixed, the other B moveable. Three cases may arise which it is necessary to discuss separately.

1. A and B non-conductors.
2. A a non-conductor, B a conductor.
3. A a conductor, and B a conductor.

571. In the first case, the electric particles are fixed upon the bodies A and B, by the unknown force which produces the non-conductibility. Unable to quit these bodies they divide with them the motions which their reciprocal action tends to impress upon themselves.

572. The forces then which may produce the motion of B, are, (1.) The mutual attraction or repulsion of the fluid of A upon the fluid of B. (2.) The repulsion of the fluid of B on itself. But it is demonstrated in mechanics, that the mutual attractions and repulsions exerted by the particles of a system of bodies on each other, cannot impress any motion on its centre of gravity; the effects of this internal action then destroy themselves upon each of the spheres; there cannot result from it any motion of the one towards the other; and the first kind of force, therefore, is the only one to which we need pay any attention. If the electricity is distributed uniformly over every sphere, each of them attracts or repels the other as if its whole electric mass were collected in its centre. Thus, if we call $a$ the distance of their centres; $r, r'$, their radii; $e, e'$, the thicknesses of the electric strata formed upon their surfaces by the quantities of electricity introduced into them; the electric mass of each of them will be $4\pi r^2 e$, $4\pi r'^2 e'$, $\pi$ being the semi-circumference of which the radius is equal to unity, and the attractive or repulsive force will be expressed by $\frac{16\pi^2 K r^2 r'^2 e e'}{a^2}$, K being a co-efficient which expresses the intensity of the force when the quantities $a, e, e'$, are each equal to the unity of their species. This force transmits itself directly to the two spheres, in consequence of the adhesion by which they retain the electric particles. We see, from this expression, that the force must become nothing, if $e$ or $e'$ be nothing, that is, if the one of the two spheres be not primitively charged with electricity. During the motion it suffers no alteration but what arises from the distance, because the two spheres being supposed of a perfectly non-conducting substance, their reciprocal action produces upon them no new development of electricity.

573. In the second case, where A is a non-conductor, and B a conductor, the sphere B suffers a decomposition of its natural electricities by the influence of A. The opposite electricities which result from this decomposition unite with the new quantity which has been introduced, and dispose themselves together according to the laws of the electric equilibrium. Here the motion of B towards A may be regarded under two points of view.

574. Suppose, first, that without disturbing the electric equilibrium of B, we extend over its surface an insulating stratum, solid, without weight, and which may remain invariably attached to it. The electricity of B, unable to escape, will press as it were against this stratum, and, by this means, transmit to the particles of the body the forces by which it is urged. The forces which then act upon the system will be, (1.) The mutual attraction or repulsion of the fluid of A on the fluid of B. (2.) The repulsion of the fluid of B upon itself, a repulsion, however, which cannot produce any motion upon the centre of gravity of B. (3.) The pressure of the fluid of B upon the insulating envelope, a pressure, again, which being exactly counterbalanced by the re-action of this coating, produces still no motion whatever. The first force, then, is still the only one to which we need pay any attention.

575. When the distance $a$ of the two spheres is very great, relatively to the radii of their surfaces, the decomposed electricities of B, are distributed almost equally over the two hemispheres situated on the side of A, and on the opposite. In that case the actions which they suffer on the part of A are nearly equal, and destroy each other; all the force then is produced by the quantities of external electricity, $4\pi r^2 e$, $4\pi r'^2 e'$ introduced into the two spheres, which, acting as if they were wholly collected in their centres, the force becomes still $\frac{16\pi^2 K r^2 r'^2 e e'}{a^2}$.

576. When the two spheres are very far from each other, the co-efficient K may be considered as constant, and the attractive or repulsive force varies not but in consequence of a change in the distance $a$. But this is only an approximation; for, to consider the matter rigorously, the electrical state of the conducting sphere B varies in proportion as it approaches A, on account of the separation which this produces in its natural electricities. Hence also the reciprocal action of the two spheres ought to vary in a very complicated manner, and it is probably to this that we must ascribe the error which appears in the experiments of Coulomb, at very small distances, when calculated by the simple law of the square of the distance.

577. The supposition of an insulating envelope, without weight, serves here merely to connect the electric fluid with the material particles of the body B, and we may always regard as such the little stratum of air with which bodies are ordinarily enveloped, and which adheres to their surfaces. Yet the same result may be obtained without the aid of this intermediary; but, in that case, we must consider the pressures produced upon the air by the electricities which exist at liberty in B. These electricities, in effect, as well those that have been introduced, as those that are decomposed on it, move towards the surface of B, where the air stops them by its pressure, and prevents their escape; they dispose themselves then under this surface, as their mutual action and the influence of the body A require, resting, for this purpose, against the

air, which prevents them from expanding. But, reciprocally, they press this air from within outwards, and tend to fly off with a force proportional to the square of the thickness of the electric stratum in every point. Decompose these pressures in the direction of three rectangular axes of the co-ordinates $x$, $y$, $z$, the one $x$ being in the direction of the straight line already alluded to, joining the centres of the two spheres, and add together all the partial sums; it will then be found, as we shall show presently, that, in the direction of the co-ordinates $y$ and $z$, they amount to nothing, and there only remains, therefore, a single resulting force, directed in the straight line C $c$, that is, towards the centre of the sphere A. When the spheres are very distant from each other, compared with the radii of their surfaces, the decomposed electricities of B press the external air, in opposite directions, with a force nearly equal, and their effects destroy each other almost exactly. There only remains, then, the effect of the quantities $e$, $e'$, introduced into the two spheres, and from this there results an excess of pressure in the direction of the lines of the centres, and expressed by $\frac{K\,e\,e'}{a^2}$, K being a constant quantity for the two spheres, that is, exactly the same as was obtained by the other method. It is evident, besides, that this expression is subject to the same limitation, since the pressures produced by the electric stratum against the external air, ought to vary with the quantity of natural electricity decomposed on B by the influence of A, in proportion as the two spheres approach each other.

578. The third case in which A and B are both conductors, is resolved exactly upon the same principles, either by imagining the two electrified surfaces covered with an insulating envelope, and calculating the reciprocal actions of the two fluids which are transmitted by means of this cover to the material particles; or in considering the pressures produced on the external air by the two electric strata, and calculating the excess of these pressures in the direction of the line which joins the two centres; only, in this case, the attractive or repulsive force of these two spheres will vary in proportion as they approach each other, not only by the difference which thence arises in the intensity of the electric action, but still farther by the decomposition of the natural electricities which will be going on in the two conducting bodies A and B.

579. To render the mathematical exactness of these considerations evident, we shall, for the preceding case, go through the calculation of the pressures exerted against the air by the quantities of electricity introduced or developed on the two spheres. For this purpose take, first, on the sphere A, any point whatever which we may denote by M. The pressure exerted at this point against the air, depends on the thickness of the electric stratum there. In this manner, the pressure for any point of either sphere calculated for the unity of the surface, will be represented by $k\,E^2$ upon the first, and $k\,E'^2$ upon the second, E E' being taken from the previous formulæ. We shall now develope, successively, these two expressions. In the first place, as the pressure $k\,E^2$ varies from one point to another with the thickness of the electric stratum, we cannot suppose it the same, but in a very small space all round the point M, a space which must be considered as a superficial element of the sphere, and which we shall call $\omega$; thus the expression K E² being calculated for the unity of surface, the pressure upon the small superficial element $\omega$ will be $K\,\omega\,E^2$. This pressure acts perpendicularly to the spherical surface A, in the direction of the radius C M; decompose it then into three others, parallel to three axes of the rectangular co-ordinates $x, y, z$, which have their origin at the centre C; the first, $x$, being in the direction of the straight line, C $c$, which joins the centres of the spheres, and the two others perpendicular to this line. To effect this decomposition, we must multiply the normal pressure K E² by the cosines of the angles which the radius C M forms with the co-ordinates $x, y, z$; that is, by $\frac{x}{r}$, $\frac{y}{r}$, $\frac{z}{r}$ since, in the formula of p. 84, we have represented by $r$ the value of the radius C M of the sphere A. We shall thus have the three following component parts

parallel to the co-ordinates $x$; $K \frac{x}{r} \quad E^2$

parallel to the co-ordinates $y$; $K \frac{y}{r}\,\omega\,E^2$

parallel to the co-ordinates $z$; $K \frac{z}{r}\,\omega\,E^2$

But we must observe, first, that it is absolutely of no use paying any attention to the two last, because the efforts which each of them makes, on the whole extent of the surface, mutually destroy each other, on account of the symmetrical disposition of the electricity relatively to the axis of the co-ordinates $x$, which joins the two centres. If we consider, in effect, the force, for example, $K \frac{z}{r}\omega\,E^2$ for the point M, situated in the figure under the plane of the co-ordinates $x, y$, we shall find above this plane, another point M′ situated quite similarly, and of which the co-ordinates $x$, $y$, $z$, will consequently be the same, with this only difference, that $z$ will there be negative, on account of its opposite situation relative to the origin of the co-ordinates. For this second point, the element $\omega$, and the pressure K E², will be also absolutely the same; $\omega$ on account of the symmetry of the surface of the sphere A; E² on account of the symmetrical disposition of the electricity round the axis of the co-ordinates $x$, which joins the centres of the two spheres A and B; but the component force which proceeds parallel to the co-ordinates $z$, will be $-\,K \frac{z}{r}\omega\,E^2$, on account of the negative sign of $z$; this force and its analogous one $+\,K \frac{z}{r}\omega\,E^2$ being equal, and in opposite directions, will mutually destroy each other, and a similar equilibrium will be equally obtained, in this kind of pressure, for all the other couples of points M, M′. which correspond on the two sides of the plane of $x, y$.

581. A similar process of reasoning will prove that the forces $K \frac{y}{r}\omega\,E^2$ will destroy each other two

and two, upon corresponding points, taken on two sides of the plane of $x$, $z$, and of which the co-ordinates will be $+x$, $+y$, $+z$ for the one, and $+x$, $-y+z$ for the other.

582. It remains, then, to consider the components of the pressures, taken parallel to the co-ordinates $x$; that is, parallel to the straight line which joins the centres C$c$, of the two spheres; and, indeed, from the symmetrical disposition of electricity round the straight line, it is evident that it cannot have any motion but in this single direction; and, consequently, these components alone must produce the tendency of the two spheres towards each other.

583. To obtain, in the simplest manner, the sum of all these components, it must be remarked, that their general expression $K\frac{x}{r}\omega E^2$ contains no variable but $x$; for cos. $u$, which enters into the value of $E^2$ is equal to $\frac{x}{r}$; it hence follows that their intensities are equal in the points relatively to which the co-ordinate $x$ is the same, and which are consequently situated upon one small circle, parallel to the plane of the co-ordinates $y$, $z$. Besides, as all these points are equally distant from the line of the centres, it is clear that the total result of the equal forces which are applied to them will be in the direction of this line; consequently, this will also be the direction of the general result of all the efforts of this kind exerted upon the whole surface of the sphere A.

584. To obtain now, easily, the sum of all these forces, parallel to the line of the centres, which is here that of the co-ordinates $x$, let us begin by joining together the values of $x$ which are equal and contrary; for the thicknesses E, of the electric stratum on the two hemispheres of A being almost equal, from the supposition that the two spheres are very distant, the pressures corresponding to opposite values $+x$ and $-x$, must be almost equal also; and, as the components which they give parallel to the co-ordinates $x$ are in a contrary direction, their sum must be reduced to a very small quantity. To introduce this circumstance, call E, what E becomes when we change $+x$ into $-x$; then the expressions of the corresponding components parallel to the co-ordinates $x$ will be,

| | | |
|---|---|---|
| On the side of the positive co-ordinates $x$, | $+K\frac{x}{r}\omega E^2$ | Tending to move the air in the direction A B |
| On the side of the negative co-ordinates $-x$, | $-K\frac{x}{r}\omega E^2$ | Tending to move the air in the direction B A |

585. We preserve the superficial element $\omega$ always of the same value, as it is exactly alike in the two cases; on account of the symmetrical form of the sphere on the two sides of the plane of the co-ordinates $y$, $z$; adding these two components to each other, with their actual sign, their sum will express the element of the total resulting force, which tends to carry the air in the direction A B. This, then, will be

$K\frac{x}{r}\omega(E^2-E^2)$, or, what is the same thing,

$$K\frac{x}{r}\omega(E+E)(E-E).$$

586. But, from the preceding formula, we have generally

$$E=e+\frac{e'r'^2}{ar}-\frac{e'r'^2(a^2-r^2)}{r(a^2-2ar\cos.a+r^2)^{\frac{3}{2}}}$$

To change $+x$ into $-x$, $+\cos.u$ must become $-\cos.u$, because $\cos.u=\frac{x}{r}$; for this second case, then, we shall have

$$E=e+\frac{e'r'^2}{ar}-\frac{e'r'^2(a^2-r^2)}{r(a^2+2ar\cos.u+r^2)^{\frac{3}{2}}};$$

consequently, by subtracting these equations from each other, we have

$$E-E=\frac{e'r'^2(a^2-r^2)}{r}\left\{\frac{1}{(a^2+2ar\cos.u+r^2)^{\frac{3}{2}}}-\frac{1}{(a^2-2ar\cos.u+r^2)^{\frac{3}{2}}}\right\}$$

or, what is the same thing, and is better adapted for approximations,

$$E-E=\frac{e'r'^2}{ar}\left(1-\frac{r^2}{a^2}\right)\left\{\frac{1}{\left(1+\frac{2r}{a}\cos.u+\frac{r^2}{a^2}\right)^{\frac{3}{2}}}-\frac{1}{\left(1-\frac{2r}{a}\cos.u+\frac{r^2}{a^2}\right)^{\frac{3}{2}}}\right\}$$

587. Since we suppose the two spheres very distant from each other, compared with the magnitude of their radii, $\frac{r}{a}$ will be a very small fraction; hence we may develope this expression for E—E into a converging series of the ascending powers of $\frac{r}{a}$, this will be effected by the binomial theorem; and taking only the first power of $\frac{r}{a}$, which, in the case we are considering, will contain an infinitely great proportion of the total result, compared with the other powers, it will become

$$E-E=\frac{e'r'^2}{ar}\left\{1-\frac{3r}{a}\cos.u-1-\frac{3r}{a}\cos.u\right\}$$

or by reduction $E-E=\frac{-6r'^2}{a^2}\cos.u$

This value of E—E must now be multiplied by E + E, to form the factor $E^2-E^2$ which enters into the expression of the total resulting force; but since E—E is already of the order $\frac{r'^2}{a^2}$, it is evident that, in E + E we must confine ourselves to the terms which are not divided by $a$; this limitation reduces the value of E + E to $2e$, and employing this to multiply E—E, there results

$$E^2-E^2=\frac{-12ee'r'^2}{a^2}\cos.u.$$

588. It only remains to substitute this value in the expression of the resulting force parallel to the co-ordinates $x$, which we have found equal to $\frac{Kx\omega}{r}(E^2-E^2)$ for the superficial element $\omega$; and by putting for $\frac{x}{r}$ its value cos. $u$, the expression will become

$$\frac{-12Kee'r'^2}{a^2}\omega\cos.^2u.$$

589. Each of these partial results is proportional to the superficial element $\omega$, and to the square of the cosine of the angle, which these elements form with the axis of the co-ordinates $x$. But, if we compare them together upon different spheres, this angle will always be expressed by the same values; for the equal values of $u$, however, the superficial element $\omega$ will vary in magnitude proportionally to the square of the radius $r$ of the sphere. Consequently, the sum of all the values of the factor $\omega \cos.^2 u$, extended to every sphere, will only vary from each other in the ratio of the square $r^2$; it may be represented then by $K'r^2$, $K'$ being a constant and numerical co-efficient which may be found, and which, in reality, is found by the processes of the integral calculus. Supposing it known then, the total result of the pressures parallel to the co-ordinates $x$ will be $\frac{-12KK'ee'r^2r'^2}{a^2}$. (1)

It will be directly proportional then to the quantities $4\pi r^2 e$, $4\pi r'^2 e'$ of external electricity which they possess, and inversely proportional to the square of the distance of the two centres. When the quantities of electricity given to the two spheres are of the same nature, whether vitreous or resinous, the values of $e$ and of $e'$ must be considered as having the same sign. In that case the expression (1) is negative; that is to say, according to what has been previously admitted, that, in this case, the air which surrounds the sphere A, is more pressed in the direction B A, than in the direction A B. It will not then press equally the sphere A, as it did before it was electrified; it will press it less on the side which is most distant from the other sphere, since it is in that direction that the electric reaction is the strongest. Consequently, if the sphere A is at liberty to move, and deprived of its weight, or if its weight be sustained by a thread of suspension, it will put itself in motion from the side where the atmospheric pressure has become the weakest, that is to say, that it will recede from the other sphere B.

590. The contrary would happen, according to our formula, if the quantities $e$, $e'$, of electricity introduced into the two spheres were of a different nature, for then it would be necessary in the calculation to give to them different signs. The formula (1), which represents the total result of the pressures exerted against the air parallel to the line of the centres, will then become positive; that is to say, according to what has been already agreed on, the external air will be more pressed in the direction A B, than in that of B A; the sphere A will move then in the direction in which the external pressure will have become the weakest, that is towards the sphere B, agreeably to observation.

591. We have hitherto only considered the effect of the pressures round the sphere A, but the same reasonings and calculations will apply to the other sphere; only we must then employ, instead of E and E, the expressions of the electric strata which correspond to them, and which we have seen to be

$$E' = e' - \frac{3er^2}{a^2}\cos.u' + \frac{5er^2r'}{2a^3}(1 - 3\cos.^2 u').$$

It might be shown for this case, as well as for the other, that there cannot be any inequality of pressure but in the direction of the co-ordinates $x$; then comparing the points of the surface, which correspond to the two sides of the plane of the co-ordinates $y, z$, we shall find that the element of the resulting force of the pressures parallel to the co-ordinates $x$, is in general expressed by $\frac{Kx\omega'}{r'}(E'^2 - E'^2)$ in representing by $E'$ what $E'$ becomes when we change $+x$ into $-x$, that is to say, $+\cos. u$ into $-\cos. u'$, the angle $u'$ being here reckoned from the point $a$, situated on the side of A upon the line of the centres. By next considering the spheres as very distant, we shall obtain in the same manner the value of $E' - E'$. Approximating no farther than the first power of $\frac{r'}{a}$, this will give $E' - E' = \frac{-6er'}{a^2}\cos. u'$. We have then only to take $E + E' = 2e'$, and putting these values in the expressions of the partial resulting force, it will become $\frac{-12Kee'r^2\omega' \cos.^2 u'}{a^2}$. It may be demonstrated as above, that the sum of the factors $\omega' \cos.^2 u'$ will be proportional to the square of the radius of the sphere B, and may besides be represented by $K'r'^2$; $K'$ being the same numerical co-efficient we have already employed. For the total resulting force then, the expression will finally become $\frac{-12KK'ee'r^2r'^2}{a^2}$, that is, exactly the same which we have obtained for the other sphere, which ought to be the case, since in these sort of phenomena action and re-action are always equal. Here, as in the example immediately above, the positive sign of the expression will signify that the resulting force of the pressures exerted against the air round the sphere B, is directed towards the other sphere, and the negative sign will signify that this resulting force is directed the opposite way. The first case will take place when the electric charges $e\,e'$ are of a contrary nature; in that case, the sphere B will advance from the side where the atmospheric pressure is weakest, that is towards A; the other case will happen when the electric charges $e\,e'$ are of the same nature, then B will recede from A.

592. The common expression for the result of the pressures vanishes for both the spheres, when $e$ or $e'$ is nothing, that is, when one of them is in the natural state. This seems to indicate that they would then neither approach nor recede from each other, while, in reality, we know that in this case they always approach. This apparent contradiction is owing to the degree of approximation at which we stopped our development of the above expression. We have supposed our two spheres very distant from each other, compared with the radii of their surfaces; the result of this is, that whatever be the quantity $4\pi r^2 e$, $4\pi r'^2 e'$ of external electricity which we have introduced into each of them, it will distribute itself almost uniformly over the two hemispneres, anterior and posterior; so that the

difference of the pressures exerted against the air by these two hemispheres, which is the only cause of motion, will be very small; and it is to this degree of minuteness that we have confined our approximations in developing $E'^2 - E_{,}'^2$.

593. If, however, the one of the two spheres, B for example, is only electrified by the influence of the other, which we always suppose very distant, the development of its natural electricities will be still very feeble, and of the same order of minuteness with that to which we have confined our approximations; but this weak electricity still dividing itself between the two hemispheres of B, in a manner nearly equal, as in the example immediately above, the difference of pressures round the two hemispheres will become very minute in a still lower degree—will become a quantity of the second order of minuteness, and, consequently, cannot be found in our developments, such as we have limited them. To obtain it complete, we must not, in the calculation of $E' + E_{,}'$ confine ourselves to quantities, independent of $\frac{r'}{a}$, but take its whole value. We shall then have, first of all,

$$E' = e' - \frac{3er^2}{a^2} \cos. u' + \frac{5er^2r'}{2a^3} (1 - 3 \cos.^2 u')$$

then changing $+x$ into $-x$, or $+\cos. u'$ into $-\cos. u'$, we shall have,

$$E_{,}' = e' + \frac{3er^2 \cos. u'}{a^3} + \frac{5er^2r'}{2a^3} (1 - 3 \cos.^2 u')$$

then adding these two expressions,

$$E' + E_{,}' = 2e' + \frac{5er^2}{} (1 - 3 \cos.^2 u').$$

594. This complete value of $E' + E_{,}'$ will now no more vanish when $e'$ is nothing; but it will be seen that the terms which remain are of the order of those which we have neglected in our first approximation. Making, then, here $e'$ equal to nothing, it remains,

$$E' + E_{,}' = \frac{5er^2r'}{a^3} (1 - 3 \cos.^2 u')$$

we also find, as before,

$$E' - E_{,}' = - \frac{6er^2}{a^2} \cos. u'$$

with these values, the expression of the partial resulting force

$$\frac{Kx\omega'}{r'}(E'^2 - E_{,}'^2), \text{ or } K\omega'(E'^2 - E_{,}'^2) \cos. u'$$

becomes $\frac{-30Ke^2r^4r'}{a^5} . \omega' \cos.^2 u' (1 - 3 \cos.^2 u')$.

595. It only remains to take the sum of it over all the extent of the surface of the sphere B; but, in this operation, the variable factor, $\omega' \cos.^2 u' (1 - 3 \cos.^2 u')$, will give a result proportional to the square of the radius $r'$ of the sphere B, and which we may consequently represent by $K'' r'^2$, $K''$ being a constant numerical co-efficient different from $K'$; thus, the total resulting force will at last be $\frac{-30KK''e^2r^4r'^3}{a^5}$.

596. This force, then, will be an order of minuteness, much inferior to that which we obtained at first, when $e'$ was not supposed to be nothing, since the radii there are divided by the fifth power of the distance of the centres of the two spheres, instead of the simple square which we had in the other approximation. It is obvious, that experiments of this kind, made with the electric balance, by charging only one of the balls, might produce an error as to the true law of the phenomena, if the theory did not throw light upon them; for one might be led to conclude from them, that the apparent attraction determined in this case is not reciprocally as the square of the distance of the centres of the two spheres, which nevertheless would be contrary to the truth: consequently, when it is meant to put this simple law of the square to the test, the balls must not be allowed to approach so near to each other, that the electricity developed by their reciprocal influence, may bear any sensible proportion to the quantities of external electricity introduced into them; and this is the reason that, in these experiments, it is always more certain to employ, instead of balls, small circular discs of gilt paper; for, on account of the thinness of these discs, the quantities of vitreous or resinous electricity developed at their surfaces, having scarcely any room to separate from each other, their actions on the exterior bodies must be always nearly alike, and cannot, therefore, alter the results any more than if their development had not taken place.

597. The theory, which we have thus explained in regard to spheres, applies equally well to bodies of any form whatever; but here the difficulty of the analysis prevents us from anticipating any thing but the general effects which the different pressures produce, without our being able to reduce them to numbers. Here it will suffice to have established the general mode of reasoning applicable to all the questions of this kind, and to have followed out the whole development for the single case, which analysis has been able as yet completely to surmount.—We shall add, that before the theory had acquired its actual precision, it could not be clearly conceived how the attractions and repulsions, which in reality only take place between the electrical principles themselves, were communicated to the material particles of the electrified bodies; and philosophers were reduced to the necessity of denoting this effect by the vague word *tension*, which represented the electricity like a kind of spring placed between the bodies and tending to make them approach or recede. A few miscellaneous illustrations, including the latest and most important discoveries, must conclude our article.

### New Galvanic Battery for Medical purposes.

598. The object of this battery is to increase the galvanic power, ad libitum, and to continue it for a great length of time, without any fresh excitation. These most desirable results are effected by a metallic and a semi-metallic substance, combined with another less oxidable metal, the surfaces of which are acted on by one or two mineral acids diluted with pure water. The power and duration obtained by these means are very great, though contrary to the hitherto acknowledged laws of galvanism, which require

two dissimilar metals and one interposed fluid to develope the galvanic influence. This apparatus is designed for philosophical experiments on animals, and for the use of an operator in full practice. It is not only capable of increased power, but, by a simple contrivance, it perpetuates its action to almost any length of time for a succession of operations; these advantages are obtained by the shape and position of the plates; for, instead of being square and stationary, as in the common battery, they are circular and made to revolve on an axis at the will of the operator. As only one segment of the circle is used at one time, several different operations may be effected in each revolution of the entire circle, without the trouble of wiping any part of the circle. A constant stream of galvanic fluid may thus be exhibited almost ad infinitum, and the unpleasant effluvia arising from the frequent addition of acid, as in the common mode, is prevented. The apparatus being concealed from view, in a handsome covered box, cannot give alarm to the most timid patient. The greatest facility is afforded in removing the oxide from the surfaces of the plates by a few revolutions round its axis, and the virtue of the acid solution in the cells remains in full strength for a very long time.

599. M. La Beaume's portable galvanic battery consists of a box containing four series of plates, and four divisions made with pieces of glass and baked wood, which are interposed to divide the box for the plates; the ends of each series are connected by a hole in the plates, so that a connecting wire is not required. There is also a space for a bottle of acid. The inside of the box cover contains the apparatus necessary for the galvanic operation. By a few simple directions the battery may be preserved in good order for some months, or even years. The cover, after the apparatus is taken out of it, is placed on the box, and, sliding into a groove, is fastened by a pin.

600. Another portable galvanic battery for suspended animation. This apparatus possesses a very great galvanic power in a small compass, and its action can be perpetuated for as long a time as may be necessary, which is accomplished by the combination of different metals. It consists of 300 or 400 plates in a box about three feet long, three inches deep, and three inches wide; the circular plates are about the size of half a crown, and when the apparatus is taken out, the box is filled with diluted nitric acid, and the row of stringed plates is placed horizontally on the two supports of the battery.

601. A third portable galvanic battery intended to be used in suspended animation from drowning, &c., is contained in a walking-stick, for the convenience of town or country practitioners, when no conveyance can be immediately obtained for a larger battery. This galvanic apparatus is contained in a hollow stick, with three divisions; the first division contains a bottle of acid, salt, and linen rag, covered by a metal cap affixed to the handle of the stick, and which is to be used as a cup to mix the acid with water. The second division is composed of two parts, one sliding on the other by means of a groove; when opened, it forms a pair of galvanic batteries of 300 or 400 plates of combined metal, which are connected together by an arched wire. The third division, which is the smaller end of the stick, contains a small lancet, the conducting wires, &c., and is also held by the hand during the operation. This stick contains all that is necessary for the galvanic process except water, which can be obtained on the spot. The power of this battery is rendered equal to the following, by the combination of the plates, the strength of the acid, and the horizontal position of the plates, which prevents the circuit of communication being formed by the expressed moisture of the interposed cloths, which must result from a perpendicular position of the pensile pile, as invented by professor Aldini, and improved by Dr. de Sanctis.

602. The most portable battery consists of a series of plates of the form and size of a shilling or a sixpence; each pair being intersected by a piece of cloth, on the principle of professor Aldini; and this battery is more powerful than his, because the semi-metal is combined with one of the other metals. This battery consists of 200 or 300 plates, and may be conveyed with perfect ease in the pocket.

### Electricity developed in Capillary Attraction.

603. M. Becquerel is said to have demonstrated, that there is a sensible development of electricity during the ascent of liquids in capillary tubes. He first obtained this result by increasing the sensibility of Schweigger's galvanometer. He placed three of these instruments together, so that the magnetic needle of the middle one deviates from its ordinary direction, by the lateral effects produced upon each of its poles by the contrary poles of the two other needles. From this arrangement it follows, that, when an electric current passes into the apparatus, tending to bring the needle into the plane of the magnetic meridian, the middle needle will be as much less retarded in its process as the poles, opposite to its own, of the other two needles are more remote from it, consequently, the oscillations will have a wider extent than if there were only one galvanometer.

604. In order to observe the electricity of capillary action, M. Bacquerel could not employ glass, as it is not a conductor of electricity; but he employed sponge of platinum, and small pieces of charcoal. Pure hydrochloric acid, much diluted with water, is poured out into the platinum dish, which communicates with one of the ends of the wire of the galvanometer; and into the dish is plunged sponge of platinum, which is fixed at the other end of the wire. At this contact there is produced an electric current, which goes from the sponge to the acid, and the direction of which is contrary to that of the current which would have been obtained if the acid had been attacked by the metal. As the interstices of the sponge are filled with the fluid, the current diminishes, and it ceases when the sponge has absorbed all the liquid which it can contain. Sometimes the current takes another direction, but the cause of that is not known.

The same effect is produced with nitric acid, but it is less marked. The same result was obtained with a small piece of charcoal, prevented from touching the platinum by a band of papier Joseph.

### Electricity developed in Solutions and Mixtures.

605. By means of the same apparatus, M. Becquerel has discovered that an electrical current goes from the acid to the water, when sponge of platinum, that has imbibed distilled water, is plunged into the dish of platinum, containing hydrochloric acid.

606. In order to observe the electricity of solutions of alkalies in water, he fixed in the platina pincers a fragment of hydrate of potassa or soda, enveloped in papier Joseph, and then plunged it into distilled water in the platina cup. A current was thus produced from the water to the alkali.

607. M. Becquerel also found that electricity was developed during the mixture of sulphuric and nitric acids.

### Electrical Effect.

608. The following effect is attributed by Mr. Fox, who observed it, to electricity. A piece of iron pyrites was fastened with a piece of brass wire in a moss-house, the moss being damp. On the following day, the wire was found broken and excessively brittle, and, in those parts in contact with the pyrites, much corroded. On one occasion, after the brass wire had been fastened once or twice round a piece of iron pyrites, and had remained for some days enveloped in damp linen, the constituents of the brass wire were separated, and it was converted into copper wire coated with zinc.

### Conduction of Electricity by Amadou.

609. It is remarked, in a late number of the Journal de Physique, that the effect of a piece of amadou, in drawing off electricity from charged surfaces, is equal to that of a metallic point. For this purpose, it requires to be dry; and, it may be observed, that at the time a number of fibres rise up and point towards the electrified surface. For the rapid abstraction of electricity, it requires, however, that besides offering points, the body should possess a high conducting power, which was not previously known to belong to this substance.

### Effect of Voltaic Electricity upon Alcohol.

610. M. Lindersdorff produced an ethereal fluid by the action of the Voltaic pile upon alcohol; and, by continued electrisation, a mixture of equal parts of alcohol and liquid ammonia lost its inflammability, and acquired a bitter flavor, yellow color, and nauseous odor.

### Improvement upon the dry Pile of Zamboni.

611. In constructing the dry galvanic pile of Zamboni with tinned paper and black oxide of manganese, M. Zamboni recommends the use of tinned paper, which, when disposed alone in the pile, has the same polarity as when it is employed along with oxide of manganese. The reason of this is, that a pile of tinned paper has electrical poles. But, whatever be the kind of paper which is used, the pile always increases in energy, and its polarity always coincides with that of a pile of tinned paper and oxide of manganese, when the paper has been impregnated with a solution of sulphate of zinc, and afterwards dried. In preparing the paper, M. Zamboni avails himself of a dry season. He spreads the solution of sulphate of zinc over the face of the paper which is not covered with tin, and having dried it, but without taking away from the paper its own natural humidity, he covers this face with very dry oxide of manganese. The pile being thus constructed, it is carefully defended from the air. If the paper is not fine and unsized, a little alcohol should be added to the solution of sulphate of zinc. The best manner of preserving the pile, as Zamboni has ascertained by long experience, is to enclose it in a glass tube, whose diameter is somewhat greater than that of the discs, and to run into the intermediate space a moderately warm cement of wax and turpentine. A pile of 2000 discs, constructed in this manner, gives a spark visible in day-light. M. Zamboni recommends the perfect insulation of all the parts of the pile that require to be insulated.

### Thermo-Electricity.

612. It was proved, by professor Sebeck, that antimony, brought into contact with another metal, and unequally heated, would cause the magnetic needle to deviate from its meridian. With a view to ascertain this fact, and to investigate whether this property was restricted to antimony, or extended to other metals, the following experiments were made.

613. (1.) A parallopiped of antimony was procured, about fifteen inches long, and one inch square. This bar was prepared by treating crude antimony with sulphate of potassa and tartrate of potassa. A slip of copper was attached to both ends of the antimony. It was kept in close contact with the antimony by means of copper rings. This bar was laid in the direction of the magnetic meridian. A needle was placed on the antimony, and the ends of the bar were successively heated by a spirit-lamp. When the heat was thus applied to the south end, the magnetic needle immediately, and strongly, deviated to the east. The extent of this deviation depends on the length, mobility, and strength of the needle. It has been seen as much as 68°. When the heat spreads more uniformly through the metal, the deviation decreases, and the needle gradually returns to the magnetic meridian.

614. Supposing the deviation to the east at its maximum, the lamp burning under the end facing the south, if it then be removed, and placed under the end facing the north, the deviation to the east will decrease, and it will change into a deviation to the west.

615. In general, if the heat is applied under the north end of the bar, the needle will deviate to the west.

### Professor Cumming's Table of Thermo-Electrics.

616. In the following table of thermo-electrics, by professor Cumming, each substance is positive to all below, and negative to all above it, two being used together.

| | | | |
|---|---|---|---|
| Bismuth, | Cobalt, | Brass, | Charcoal, |
| Mercury, | Silver, | Copper, | Plumbago, |
| Nickel, | Tin, | Gold, | Iron, |
| Platina, | Lead, | Zinc, | Arsenic, |
| Palladium, | Rhodium, | | Antimony. |

### Analogy between the Phenomena of Galvanism and those of Fermentation.

617. M. Schweigger has observed this analogy in the following points:—

618. (1.) Galvanic piles, like fermentable mixtures, exhibit their effects only by the reciprocal action of three different bodies.

619. (2.) The products of galvanic action are two, an oxidated body, and a hydrogenated body. The same happens with the products of fermentation, which are alcohol and carbonic acid.

620. (3.) The presence of electro-negative bodies favors the decomposition of water, whilst, according to Dobino, a similar effect goes on in fermentation.

### Experiments on the Ignition of Wire.

621. The following experiments on the ignition of wires are very interesting. Being connected with the phenomena of caloric developed in the action of the galvanic battery, they may be acceptable as a contribution towards that mass of facts which will at some future period assume a more scientific form.

622. In these experiments, Mr. Murray used four porcelain troughs, each containing ten cells, and each cell supplied with one and a half fluid ounce of the strongest nitrous acid, being filled up with water to the depth of two-thirds, and properly mixed with a glass rod. Nitrous acid, in this proportion, he has ever found best calculated for the development of galvanic action. Fifteen to eighteen inches of fine platinum wire may be readily ignited. He of course used the triad (four inches square), for which we are indebted to the sagacity of that ingenious and profound philosopher, Dr Wollaston.

623. When sulphuric acid is employed, as is done most injudiciously by some, in mixture with the nitrous acid, the vapor is perfectly intolerable, and much of the action is no doubt lost and expended in vapor, and in the great temperature developed at the same time.

624. In connexion with the subsequent detail, it may be proper to mention, that a riband of a platinum foil, was suspended from one of the conductors, and brought in contact with the mercurial surface (that metal being contained in a shallow glass-basin), while the other one is plunged into the mercury, deflagrates with great brilliancy, and oscillates like a pendulum.

625. We may now state generally, that steel and platinum wires may be intensely ignited, in alcohol. ether, and its vapor, oil of olives, naphtha, and sulphuret of carbon. Mr. Murray has not succeeded in igniting these in water, and concludes that it is owing to the superior conducting property of that fluid. The degree of ignition, all circumstances being the same, will correspond with the relations in which the medium containing the wire stands to conduction.

626. Platinum and steel wires may be ignited in carbonic acid gas, hydrogene, cyanogene, and olefiant gas.

627. Gold wire was wrapped round platinum in all its extent; and this double wire placed as the uniting wire between the conducting rods It was ignited throughout, and the fusion of the gold wire supervened, the gold being collected into little spheres of a prolate form, at equal distances, and appearing like a row of beads.

628. Steel wire was, in like manner, entwined with gold wire. It also was ignited in its whole extent; the gold wire was fused, and exhibited the bead-like form.

629. Platinum was woven with copper wire. The platinum wire was ignited throughout; the copper wire not undergoing fusion nor even ignition.

630. It may here be remarked, that, in the ignition and combustion of steel wire, for instance, the fusion is primarily confined to the surface, and the fused scale or film may, perhaps, not penetrate more than one-third the diameter of the wire, while the remaining part may not have undergone the least physical change. The fused matter formed itself into spherules, with regular intervals. This appears to be a curious phenomenon; and it will also be observed that, when the calorific heat is short of ignition, the steel wire will be blued in patches.

631. Steel wire was doubled for one-half its extent; the single and denuded part was alone ignited.

632. Platinum wire was doubled for one-half its extent; and that part only which was single could be ignited.

633. Steel wire was partly enveloped in gold wire; only that portion of the steel wire which was void of the gold wire could be ignited; the part encased in the folds of the gold wire was partially blued, and was rendered magnetic.

634. Copper wire was twisted round platinum wire, for half the length of the latter. The uncovered platinum was alone ignited. Copper wire was twisted around steel wire in the manner of the preceding; the naked steel wire was ignited alone. Steel wire was twisted round platinum wire, for one-half its length; only that portion of the platinum wire excepted from the steel could be ignited.

635. Peculiar phenomena are connected with these exhibitions. When the second wire is carried through the whole extent of the uniting wire, ignition is superinduced throughout; but when only partial, the ignition is confined to the denuded portion.

636. Copper, platinum, and copper wires, were linked together, and made the communicating chain. The platinum placed between the copper wires was ignited alone.

637. Platinum, copper, and platinum wires, exhibited, on the tract of either platinum wire, ignition, while the intermediate copper wire remained dark and unignited.

638. In the case of steel, copper, and steel wires (so linked together), the steel wire on each side was ignited, while the copper wire remained unaltered.

639. In the chain of platinum, steel, and platinum wires, the platinum wires were exclusively ignited, and the steel unignited.

640. In that of steel, platinum, and steel, the intermediate link of platinum was ignited, and the steel wire on each end remained without ignition.

641. In a chain of gold, steel, and gold, the gold wires on each end were ignited and fused, and the intermediate steel was not ignited.

642. In one formed of steel, gold, and steel wires, the central one of gold was exclusively ignited.

643. Mr. Murray next tried spiral coils of platinum and steel, of various diameters, and found that they were ignited, though curvilinear, in the same manner as if the wires were not curved.

644. The preceding experiments seem to prove, that the caloric developed in galvanic action, has no relation with the medium in which the ignition takes place; and that it is evolved in some inverse ratio of the conducting properties of the uniting wire.

645. The phenomena of ignition in links of various metals united into a chain, seem connected with the passage of a material agent through them, displaying its powers in greater or less ignition, according as the passage is interrupted, or its fire more or less retarded, and, of course, as the amount of the resistance. The agent or agents, therefore, developed in transitu from pole to pole, will swell into ignition, if the conducting power of the medium traversed is low, or even burst its metalline confine, and expend its impetus in all the brilliancy of an intense combustion. The gold, platinum, and copper wires, were $\frac{1}{100}$th of an inch in diameter; and the steel the finest harpsichord wire.

### Description and Use of a very Sensible Electrometer, for indicating the Kind of Electricity which is applied to it.

646. Some years back, M. Behrens published the Description of an Electrometer, which indicates the kind of electricity that is presented to it; but it appears to have been forgotten, with the dry electrical columns, which formed an essential part of the apparatus. The electrical perpetual motion of Zamboni is similar to this electrometer, and M. Butzengeiger was employed to execute one of them, which we may proceed to describe.

647. A cylindrical vessel of glass about two inches and a half in diameter, and three and a half high, has fitted to it a brass cap, from which two small dry electrical columns descend into the vessel, and are attached to the cap by screws, so that the one has its positive and the other its negative pole, making a slight projection above the cap. Each column is composed of 400 discs of gold and silver paper, glued together, and three lines in diameter, so as to fill two tubes of varnished glass. Each of these tubes is terminated below by a ring of brass, projecting a little, and rounded, which is in electrical communication with the discs. When the brass cap is in its place, the columns descend vertically, and the lower ring is one-fourth of an inch distant from the bottom of the glass. The axes of the columns are one inch and seven lines distant, but may be brought nearer one another. From the centre of the cap rises a tube of glass, varnished within and without, and within the tube is a brass wire kept in the axis by a cork, but touching the tube no where else. At the lower end of the brass wire is suspended a piece of gold leaf, two inches and a half long and three lines wide, exactly in the middle of the interval between the two columns, and parallel to their axis, if they are accurately vertical. At the upper end of the brass wire is a small brass ball, upon which may be screwed one of the discs of a condenser, as in the electrometer of Volta. By this arrangement, the electrical columns which Behrens had placed without the glass, which defends the gold leaf from the agitations of the air, are placed within the glass, so that their position is not only better preserved, but they are defended so completely from moisture, dust, &c., that they retain the same electrical intensity.

648. This electrometer is used in the following manner:—The cap of metal is put in communication with the ground by means of a metallic wire, and by touching the brass ball, any accidental electricity is discharged, which may belong to this part of the apparatus. If the skin is dry, the touch of the finger is not sufficient. As the gold leaf is suspended between the columns, at the level of the rings of metal which terminate them, the one positively and the other negatively, the gold leaf is attracted equally on both sides, and remains quietly in the middle in its ordinary state; but if, by means of the metallic wire, we communicate to it the weakest degree of electricity, the lower extremity of the gold leaf is attracted by the ring which possesses an electricity opposite to that which is communicated. Having come in contact with this ring, it is successively repelled and attracted by the opposite ring. This oscillatory motion continues till the gold leaf attaches itself to one of the columns, from which it may be easily detached by touching the brass wire, so as to dissipate its electricity, and by shaking the instrument. In order to determine the nature of the electricity, the upper poles of the two columns which project above the brass cap have the signs + and — upon them, and the electricity required is that which is indicated by the sign of the column towards which the gold leaf first moves, or which it first touches, when the electricity is stronger.

649. By this electrometer, strong and weak degrees of electricity may be equally well examined. In the first case, the electrified body is made to approach slowly and at a distance the ball of the electrometer, till the gold leaf is put in motion towards one of the columns. If, for example, we bring an excited stick of sealing-wax to the distance of about three feet from the ball, we shall observe a motion of the gold leaf towards the column marked —. If we bring it to a less distance, it will strike the column, from which it may be easily detached,

by bringing the wax still nearer. In the second case, the electrified body must be moved much nearer the ball, and brought into contact with it, if necessary, till the gold leaf is put in action. This degree of electricity is so weak, that it would be absolutely insensible in the ordinary electrometer of Bennet.

650. When the electricity is still feebler, we may advantageously employ a condenser adapted to the instrument. The circular plate, on the margin of which is screwed the ball of the electrometer, replaces the cover of the condenser, and a plate of disc furnished with a glass handle, and which is placed above the first, represents the base. These plates are covered with a thin coating of amber varnish on the faces which are brought into contact. If we wish to try a very weak electricity, we first touch, in order to deprive it of its electricity, the inferior plate, or the wire which carries the ball; we then place above it the other plate, and afterwards touch the lower plate or its wire, with the body whose electricity we wish to examine, touching, at the same time, the upper plate, in order to deprive it of its electricity. The upper disc is then removed by its glass handle, and we observe towards which of the two small columns the gold leaf is carried, and the sign marked upon this column will indicate the kind of electricity. If, for example, we put in contact with the lower surface of the lower plate of the condenser a small disc of zinc, about three-fourths of an inch in diameter, and press it against this plate, without touching the plate with the finger, and if we touch at the same time the upper disc of the condenser, to deprive it of its electricity, and if we afterwards remove the disc of zinc on one side, and on the other side the upper plate, we shall observe the gold leaf approach the column marked *minus*. A similar effect will be observed, if we put in contact with the disc of the apparatus the metallic side of a piece of silvered paper.

651. It will often be more convenient to put the body we wish to examine in contact with the upper and moveable plate, and touching the inferior plate, to deprive it of its electricity, proceding in other respects as we have already described. The electricity, however, which the instrument now indicates, will be opposite to that which is communicated to the upper plate, because, by this method, the plate united to the instrument forms the base of the condenser.

652. If the body which we examine cannot be conveniently put in immediate contact with the lower plate of the condenser, a communication with it may be formed, by means of a metallic wire, with an insulating handle, the rest of the operation being the same as before.

## Electro-magnetic Effects of Alkalies, Acids, and Salts, by M. Yelin.

653. The magnetic needle used by M. Yelin was nearly 1·5 inch long, and ·008 of an inch in diameter. It weighed little more than half a grain, and was delicately suspended by a spider's web, from a rod passing through the top of a glass cylinder, so that it could be raised or lowered at pleasure. The bottom of the instrument is a piece of card-board, on which circles are marked and divided, indicating the number of degrees through which the needle may have moved.

654. The conductor, whose state was to be indicated by this needle, was sometimes a band of tin 0·4 of an inch broad, and 24 inches long; sometimes a brass-wire helix, which, being brought up close beneath the needle, formed a kind of condenser, and rendered the action more sensible.

655. (1.) The tin band was placed under the needle, both being parallel to the magnetic meridian; a small glass was filled with muriatic acid; the end of the band, towards the austral pole of the needle, was plunged into the acid, and, in a few moments after, the other extremity was immersed; immediately the austral pole went to the east. The experiment being repeated, except that the end of the band, corresponding to the boreal of the needle, was first immersed; the austral pole went to the west. When, in place of muriatic acid, a solution of ammonia, mineral alkali (soda), or sal-ammonia, was used, the results were exactly the same; but if a solution of vegetable alkali (potassa) was used, the deviations were all in the opposite directions. Pure water produced no effect, but $\frac{1}{500}$ of acid made it active. All solutions of salts, or acid, thus applied, produced an effect upon the needle. It appears in these cases that, according as the first contact is made to the right or left, an arrangement of molecules is established in the fluid, proper to form a species of pile of which the two poles are very distinct, and that the whole of this little pile is reconstructed in the opposite direction, when the contact is made in the opposite way.

656. Place the needle over the condenser, the wires of the latter and the needle being parallel to the magnetic meridian; hold a cylinder of zinc in perfect contact with each end of the wire of the condenser, the arrangement will then be zinc, brass, zinc; plunge the cylinder corresponding with the austral pole of the needle into muriatic acid, and then plunge the other into the same acid, the austral pole of the needle will go towards the east. Repeat the experiment with nitric acid and fresh cylinders of zinc; now the austral pole of the needle will go towards the west. These and other results are the same, whether the conductors are put in contact with the metals before or after their immersion in the fluid.

657. The needle condenser and metal bars (zinc), being as before, let the glass be filled with a solution of potassa, then immerse the end of the bar corresponding to the austral pole of the needle, and afterwards the other bar; the austral pole will deviate to the east. Take the bars out of the solution, but without changing their position in the hands, and, as soon as the needle is at rest, introduce them again beginning with the bar corresponding to the boreal pole of the needle; the needle (the austral pole) will now deviate to the west. Take the bars out of the fluid, and, without changing them from hand to hand, turn them so that the ends which were before immersed in the liquid, shall now be in contact

with the extremities of the condenser wire, then repeat the above experiments, and the same results will be obtained. Finally, if the bars, being well cleaned, are changed from hand to hand, and the experiments again repeated, the same results will be produced.

658. But now, preserving the apparatus as it was, change the solution of potassa for very pure muriatic acid. The zinc bar, corresponding to the boreal pole, being first immersed in the acid, the austral pole will go eastward. Remove that bar from the acid which was last plunged in, and a little while after, the other bar, and without changing them at all in the hand, wait till the needle is quiet; commence by the bar corresponding to the boreal pole; at the moment when that which agrees with the austral pole shall touch the acid, the needle (the austral pole) will deviate towards the west, and it will go in the same direction as often as the experiment is repeated, whether the operation be begun on the right or on the left hand.

659. If the bars be then well washed and dried, and restored to the ends of the condenser wire they were in contact with before, but with that part which was before immersed, now in contact with the wire, and the immersions and experiment be repeated, one of these two things will happen: either the needle will constantly move to the east, whichever bar is first immersed, or the action will be very doubtful or null.

660. If, instead of turning the bars, they are changed one for the other, the needle will go constantly to the west, whichever bar is first immersed; but the previous results may be at any time restored by re-changing the bars, and then the needle will go to the east.

661. The faculty thus acquired by the bars of zinc, of becoming positive or negative, according as they are plunged either first or last in the acid, they preserve some time. They may be washed, dried, and held in the hand, without losing their state, and hence particular precautions are required in making delicate experiments with the metals.

662. This faculty is not communicated either to the fluid or to the extremities of the condenser wire. All the metals which become magnetometers by muriatic acid, as well as all the acids which produce an electro-magnetic action with homogeneous metals, produce the same phenomena.

663. These experiments may be compared, with interest, with the observations of M. Volta, that a band of wet paper, making part of the conductor of his pile, becomes charged with electricities, which it preserves some time; with that of M. Gautheret, who thought he remarked something similar in the conducting wires of the pile; and with that of M. Ritter on his secondary piles, the phenomena of which M. Volta attributed to the electro-motive action of the alkalies and salts interposed. 'A very decided electric charge may be remarked in the metals interposed between the conductor and the fluid; they are both unipolar, i. e. charged each with a single electricity, which they retain for some time, and this electricity is constantly positive in one, and negative in the other. They form, therefore, the elements of a species of pile, of which the extremities may be detached without losing their electricity; and, in consequence of this property, I call it a secondary pile, with mobile unipolar extremities.

664. 'I have sometimes succeeded, with bars of some length, in obtaining distinct poles at each extremity, so that when the bars were turned, opposite results were presented by the needle; but I have not been able to discover the condition of this phenomenon, so as to be able to produce it at pleasure.'

665. M. Yelin remarks, however, that he has never yet been able to ascertain the existence of free magnetism, or electricity, in any of these bars. Many other experiments are given in tables, which we have not room to notice, though they are of great interest. The bars M. Yelin used were ·275 of an inch in diameter, and 2·75 inches long.—*Bib. Univ.* xxiii. 38.

### Terrestrial Magnetism.

666. The following curious electro-magnetic experiment was exhibited by Dr. Birkbeck, at the London Institution. A hollow globe of wood, fifteen inches in diameter, was first accurately turned, and, from the equator towards each extremity of its axis, grooves were cut parallel to the equator, at the distance of 4½° from each other, like parallels of latitude, and another, rather deeper, groove from one pole to the other, along a meridian half-round.

667. Beginning now at the equator with the middle of a wire, about ninety feet in length, and one-tenth of an inch in diameter, which just fitted the grooves, it was carried round in the successive circles towards each pole, making an abrupt turn from one circle to another along the meridian groove above-mentioned. From the point where the wire arrived at the poles, it was carefully bound with silk, and returned back again to the equator along the same meridian. The two ends of the wire being thus brought together, they proceeded to a little distance from the globe, where they terminated. By this means the effect of the short abrupt turnings of the wire along the meridian towards the poles, is counteracted by wire returning back again from the poles to the equator, leaving thereby only the parallel wires active when the two extremities are connected with the battery.

668. The globe being thus far formed, it is covered with zones, in the usual way, so as to exhibit to appearance a common fifteen-inch terrestrial globe, the wire being completely hidden. But this covering is so laid on that, instead of the terrestrial pole coinciding with the poles formed by the wire, the latter is brought into lat. 75° N., and long. 76° 40′ W., which is the situation which Mr. Barlow conceives will best agree with the observed bearings of the needle in most parts of the world. Things being thus adjusted, the globe is placed on a large cup near the battery, so as to admit of its being placed in any position, or so as to bring any part to the zenith, without the encumbrance of the usual brazen meridian and horizon. A needle is now suspended over the globe, leaving it free to take any dip; while, by means of a silk suspension, it is

also free to take any direction; lastly, the needle is insulated from the action of terrestrial magnetism, by opposing to it the north end of a small bar magnet in the line of the dip. By this means the needle retains its magnetic power, but is under no magnetic influence.

669. The extremities of the curves being now connected with the poles of the battery, the globe immediately becomes strongly active upon the needle, causing it to assume the same dip, and the same direction, with respect to the artificial globe, as the actual needle does in the corresponding part of the earth itself, at least to a very considerable extent. Thus, if we bring the Island of Ascension to the zenith, the needle is found perfectly horizontal, with a slight westerly variation. If we bring London to the zenith, we find the dip about 70°, and 24° or 25° of westerly variation; if the globe is again shifted in position, so as to bring Cape Horn in the zenith, the dip is about 60° the contrary way, that is, with the south end below; and the variation about 30° easterly, and so on with various other places.

670. The purpose of this experiment is to show, that what we have hitherto considered as the magnetism of the earth, may be only modified electricity, and to illustrate, experimentally, the theory advanced by M. Ampère, who attributes all magnetic phenomena to electrical results.

### Rousseau's Apparatus.

671. M. Rousseau, who has been occupied several years in the construction of dry Voltaic piles, has conceived the idea of employing those instruments to appreciate the different degrees of conducting power of the substances arranged in the class of bad conductors of electricity. For this purpose he has contrived the apparatus we are about to describe. The dry pile, which forms the principal part of it, is made of discs of zinc and tin-foil, separated by pieces of parchment, soaked in a mixture of equal parts of oil of poppies and essence of turpentine; the whole is covered laterally with resin, to prevent the contact of the air. The base of the pile communicates with the ground. Its upper extremity may be connected by a metallic wire with an insulated vertical pivot, carrying a weakly magnetic needle, balanced horizontally. On a level with the needle, and distant from the pivot, about half the length of the latter, is a metallic ball, also insulated, but communicating with the pile. It is evident that, by this arrangement, the electricity accumulated at the upper pole of the pile is communicated to the needle and the ball; and consequently repulsion ensues, tending to separate the needle, which is moveable, from the ball which is stationary. If we place the pivot and the ball in the magnetic meridian, the needle touches it, and remains at rest as long as the apparatus is not connected with the pile; but the instant the communication is established between them, the needle is repelled; and, after some oscillations, takes its position of equilibrium, depending on its magnetic power and the energy of the pile. These two quantities remain constant for a considerable time, with the same apparatus, as may be ascertained by determining the angle which the needle makes with the magnetic meridian, after it has assumed a fixed position, by means of a divided circle adapted to the cage which covers it. A simple conducting needle, suspended by a metallic wire of proper diameter and length, might be substituted for the magnetic one; but M. Rousseau's apparatus is much more convenient, and sufficiently sensible for the kind of effect which it is his object to measure.

672. To use it for ascertaining different degrees of conducting power, it is sufficient to place the substance submitted to experiment in the electrical current, taking care that the thickness which the electricity has to pass through be always equal. If the flow of the quantity of electricity necessary to produce the greatest deviation be not instantaneous, the time required by the needle to assume its fixed position may be taken as the measure of the degree of the conducting power of the substance employed.

673. To submit liquids to this kind of examination, M. Rousseau places them in small metallic cups, communicating by their foot with the needle and the ball: he then places in the liquid one of the extremities of the metallic wire, covered with gum lac, that the same surface of metal may always be in contact with the fluid, and measures the duration of the needle's motion from the moment when the communication is established with the pile by the other extremity of the wire.

674. By submitting the fixed vegetable oils employed in the arts and in domestic economy to this kind of proof, M. Rousseau has established a very singular fact, which may be useful in commerce; it is, that olive oil possesses a very inferior degree of conducting power to that of all other vegetable or animal oils, which nevertheless present, in all their physical properties, the strongest analogies to that substance. For instance, every thing being equal in both cases, olive oil required forty minutes to produce a certain deviation, while poppy oil, or the oil of the beech-mast, required only twenty-seven seconds to produce the same deviation. One-hundredth part of any other oil added to oil of olives reduces the time to ten minutes. It would, therefore, be easy to discover, by means of this instrument, the smallest traces of any oil fraudulently mixed with oil of olives.

675. If the proportion of the foreign substance be considerable, the difference of time necessary to produce the maximum of effect would no longer be sufficiently great, and could not be measured with sufficient precision to indicate the proportion of the elements, but the apparatus might easily be modified so as to adapt it to this kind of determination.

676. The solid fats are worse conductors than the animal oils, arising, no doubt, from the large proportion of stearine contained in the former; for M. Rousseau is satisfied, by comparative trials with stearine and elaine, prepared by M. Chevreul, that the conducting power of the latter much exceeds that of the former. The fat of an animal becomes a worse conductor in proportion to the age of the individual which affords it.

677. By means of the same apparatus, we

may also observe a considerable difference between resin, gum-lac, and sulphur, the most insulating of all known substances, and silk, crystal, and common glass.

678. M. Rousseau has not found any difference in the conducting power of liquids, whether spirituous or aqueous, acid, alkaline, or neuter, the time required by the needle to arrive at the maximum of deviation being too short, in every case, to ascertain the inequality of its duration. But a modification of the apparatus, similar to that for determining the proportions in an oleaginous mixture, would easily point out that difference.

679. It would be equally possible, and very curious, to try the effect of the two kinds of electricity on different substances; all that would be necessary would be to place the two poles alternately in connexion with the ground. According to Ermann's results, it is probable that a difference would be found between most substances.

# INDEX.

ELECTRUM, Gr. ηλεκτρον. Amber: or a mixed metal, according to some authors. See ELECTRE, ELECTRICITY, and below.

*She of whose soul, if we may say 'twas gold,*
*Her body was the electrum and did hold*
*Many degrees of that.* — *Donne.*

ELECTRUM, Lat. Ἤλεκτρον, Gr. Electrum, according to Ovid, was that resinous substance now called amber; of which there are two kinds, the white and the yellow. Sometimes its color approaches to a hyacinthine red. Also, according to Pliny (lib. xxx. cap. 4), a mixture of gold and silver, of which the fifth part was silver. According to other ancient writers, they had three varieties of substances called electrum, that were used in the arts; namely, glass, a compound metal, and succinum. In the Homeric poems electrum is often mentioned, which seems to have been succinum, the yellow or white amber. According to Eustathius the ancients used sometimes to call gold by this name, probably from its brilliancy, the word ἠλέκτωρ signifying the sun. Pliny thinks that the alloy is the same that Homer mentions in the fourth book of the Odyssey, in describing the palace of Menelaus, which he says was ornamented with gold, electrum (ἤλεκτρον), silver, and ivory. The scholiast upon Aristophanes, supposes that the electrum of Homer was glass, but there is nothing in any of his works to warrant such a supposition, for glass is not designated by any character. It is more probable that electrum was yellow amber, which has a resplendent sunny brilliancy according with its Greek name; and Herodotus mentions that succinum or amber was known to the ancients. Pliny says, all gold is naturally alloyed by silver in various proportions; some containing a tenth, some a ninth, and some an eighth part. Wherever the silver amounts to a fifth of the mass, the compound is called electrum; this alloy may also be prepared artificially, by adding to gold the requisite proportion of silver. But if this latter exceeds a fifth of the whole, the mass ceases to be malleable. The nature of electrum is to reflect a richer lustre by lamp-light than pure silver does. That which is native has also the additional property of detecting poisons, iridescent rings passing rapidly over the surface of the cup, accompanied by a noise like that of hot metal plunged in water.

Electrum was not only used for ornamental plate, but was occasionally employed for coin, at least for medals. Thus Lampridius, in his life of Alexander Severus, says that that prince caused medals to be struck in honor of Alexander the Great, both of electrum and gold. (Electreos aliquantos, sed plurimos tamen aureos.) The Romans themselves appear to have preferred the white lustre of silver to the yellow radiance of gold, &c. probably this taste together with the imperfection of the art of assaying, as practised by them, aided also by an idle superstitious notion of the efficacy of electrum in detecting poison, contributed to give to this alloy a temporary celebrity. Modern taste, however, prefers the native lustre of the noble metals in all their purity to any alloy of them with each other, nor is it probable, that the Roman electrum will ever again be met with at the mint or on the sideboard. There are many coins of this alloy of the kings of Bosphorus, some small ones of Syracuse, and many Celtic and of ancient Gaul.

ELEC'TUARY, *n. s.* Fr. and Belg. *electuaire;* Ital. *elettuario;* Span. and Port. *letuario;* Lat. *electuarium;* all from Gr. εκλεκτηριον, εκλεγω, eligo, to choose—Minsheu. But Vossius and Gesner prefer εκλειγμα, from εκλειχειν, to lick; as the etymology. A form of medicine made of conserves and powders, in the consistence of honey. The modern pharmacopœias treat of these articles as confections.

We meet with divers *electuaries,* which have no ingredient, except sugar, common to any two of them. — *Boyle.*

*Electuaries* made up with honey or syrup, when the consistence is too thin, ferment: and when too thick, candy. By both which the ingredients will be altered or impaired. — *Quincy.*

ELEEMOSYNA ARATRI, ELEEMOSYNA CARUCARUM, or pro aratris, in our ancient customs, a penny which king Ethelred ordered to be paid for every plough in England towards the support of the poor. It is sometimes also called eleemosyna regis, because first appointed by the king.

ELEEMOSYNARIUS, in old records, the almoner, or officer who received the eleemosynary rents and gifts, and distributed them to charitable uses. See ALMONER.

ELEEMOS'YNARY, *n. s.* & *adj.* Gr. ελεημοσυνη; ab ελεος, compassion. One who lives upon alms: as an adjective it means given in charity or living upon it.

It is little better than an absurdity, that the cause should be an *eleemosynary* for its subsistence to its effects, as a nature posterior to and dependent on itself. — *Glanville's Scepsis.*

In the year 1430, it appears that the *eleemosynary* boys, or choristers, of that monastery acted a play. — *Warton. History of English Poetry.*

EL'EGANCE, *n. s.* }
EL'EGANCY, }
EL'EGANT, *adj.* }
EL'EGANTLY, *adv.* }
Fr. *elegance;* Ital. *eleganza;* Lat. *elegantia, elegans, ab eligere,* to choose. The beauty of propriety, not of greatness, says Dr. Johnson. Rather that which is selected or chosen because it pleases: hence applied particularly to objects of taste. Milton uses the adjective for accurate in discernment, or nice in taste.

St. Augustine, out of a kind of *elegancy* in writing, makes some difference. — *Raleigh's History.*

They describe her in part finely and *elegantly,* and in part gravely and sententiously. — *Bacon.*

Lovers are anxious to trick themselves out; to be spruce in their apparel; to have their locks neatly combed and curiously curled; to adorn their shoes with *elegant* ties; to be point device in all their accoutrements. — *Burton.*

Now read with them those organic arts which enable men to discourse and write perspicuously, *elegantly,* and according to the fittest style of lofty, mean, or lowly. — *Milton.*

*In a poem elegantly writ,*
*I will not quarrel with a slight mistake.*
— *Roscommon.*

These questions have more propriety, and *elegancy*, understood of the old world. *Burnet.*

My compositions in gardening are altogether Pindarick, and run into the beautiful wildness of nature, without the nicer *elegancies* of art. *Spectator.*

Polite with candour, *elegant* with ease. *Pope.*

Whoever would write *elegantly*, must have regard to the different turn and juncture of every period: there must be proper distances and pauses.
*Pope's Odyssey, Notes.*

There may'st thou find some *elegant* retreat.
*London.*

The *elegant* arts owe their choicest beauties to a taste for the contemplation of nature. *Percival.*

If we can direct the lights we derive from such exalted speculations upon the humbler field of the imagination, whilst we investigate the springs, and trace the courses of our passions, we may not only communicate to the taste a sort of philosophical solidity, but we may reflect back on the severer sciences some of the graces and *elegances* of taste, without which the greatest proficiency in those sciences will always have the appearance of something illiberal.
*Burke.*

This cap to my cousin I owe;
She gave it, and gave me beside,
Wreathed into an *elegant* bow,
The riband with which it is tied. *Cowper.*
And that vice,
Though well perfumed and *elegantly* dressed,
Like an unburied carcass tricked with flowers,
Is but a garnished nuisance, fitter far
For cleanly riddance, than for fair attire. *Id.*

His infant muse, though artless, was not mute:
Of *elegance* as yet he took no care;
For this of time and culture is the fruit;
And Edwin gained at last this fruit so rare;
As in some future verse I purpose to declare.
*Beattie.*

ELEGIT, in law, a writ of execution, which lies for a person who has recovered debt or damages; or upon a recognizance in any court, against a defendant who is not able to satisfy the same in his goods.

EL'EGY, *n. s.* }
ELE'GIAC, *adj.* }
ELE'GIAST, *n. s.* }
Fr. *elegie;* Ital. Span. and Lat. *elegia*, of Gr. ελεγος, complaint or grief. A plaintive or funeral poem. An elegiast, or elegist, is a writer of such poems.

He hangs odes upon hawthorns, and *elegies* upon brambles, all forsooth deifying the name of Rosalind.
*Shakspeare.*

So on Meander's banks, when death is nigh,
The mournful swan sings her own *elegy*. *Dryden.*
Let *elegiac* lay the woe relate,
Soft as the breath of distant flutes. *Gay's Trivia.*

ELEGY is derived from the Greek ελεγεια; but who was the inventor of elegiac poetry is not known. Horace acknowledges himself ignorant of it. Among the Latins, the principal writers of elegiac verse were Propertius, Ovid, and Tibullus; the latter of whom is esteemed by Quintilian the best elegiac poet; but the former is preferred by the younger Pliny. Among the Greeks, Callimachus, Parthenius, and Euphorion, were the principal writers of elegy. See POETRY.

EL'EMENT, *n. s.* & *v. a.* }
ELEMENT'AL, *adj.* }
ELEMENTAR'ITY, *n. s.* }
ELEMENT'ARY, *adj.* }
Fr. *element;* Span. Port. and Ital. *elemento;* Lat. *elementum.* According to Vossius from old Lat. *eleo*, (*oleo*), *cresco*, to increase; because all things are supposed to proceed from certain elements. A first, or constituent principle: hence an ingredient or constituent part; and that which is proper, or agreeable, to a person or thing. The verb, derived from the noun, is used by our old writers for to compound with elements, to constitute. Sometimes 'the element,' when used alone, signifies the air. Elementarity is simplicity of nature; the state of being uncompounded: elementary, having but a single or simple principle; initial; made of, or belonging to, the elements.

We, when we were children, were in bondage under the *elements* of the world. *Gal.* iv. 3.

The heavens and the earth will pass away, and the *elements* melt with fervent heat. *Peter.*

Every parish should keep a petty schoolmaster, which should bring up children in the first *elements* of letters. *Spenser.*

With religion it fareth as with other sciences; the first delivery of the *elements* thereof must, for like consideration, be framed according to the weak and slender capacity of young beginners. *Hooker.*

If nature should intermit her course, those principal and mother *elements* of the world, whereof all things in this lower world are made, should lose the qualities which now they have. *Id.*

He (a courtier) is not, if he be out of court, but, fish-like, breathes destruction, if out of his own *element*. *Sir T. Overbury.*

The king is but a man: the violet smells to him as it doth to me; and the *element* shews to him as it doth to me. *Shakspeare.*

The king,
Contending with the fretful *elements*,
Bids the wind blow the earth into the sea,
Or swell the curled waters. *Id. King Lear.*

Who set the body and the limbs
Of this great sport together as you guess?
——One sure that promises no *element*
In such a business. *Id. Henry VIII.*

We are simple men; we do not know she works by charms, by spells, and such daubry as is beyond our *element*. *Shakspeare.*

A prince should watch that his reason may not be so subdued by his nature, as not to be so much a man of peace as to be a jest in an army; nor so much a man of war, as to be out of his *element* in his council.
*Saville.*

Here be four of you, able to make a good world for you are as differing as the four *elements*. *Bacon.*

Not all, as if some perished by this,
But so as all in you contracted is:
As of this all, though many parts decay,
The pure, which *elemented* them, shall stay.
*Donne.*

Have not all souls thought,
For many ages, that our body's wrought
Of air, and fire, and other *elements?*
And now they think of new ingredients. *Id.*

Sure it is but an *elementary* fire that goes out; that which is celestial continues.
*Bp. Hall. Contemplations.*

Our torments may, in length of time,
Become our *elements*. *Milton.*

Leeches are by some accounted poison, not properly, that is by temperamental contrariety, occult form, or so much as *elemental* repugnancy; but, inwardly taken they fasten upon the veins, and occasion an effusion of blood. *Browne.*

A very large class of creatures in the earth, far above the condition of *elementarity*.
*Browne's Vulgar Errours.*

He from his flaming ship his children sent,
To perish in a milder *element*. *Waller.*

A man may rationally retain doubts concerning the number of those ingredients of bodies, which some call *elements*, and others principles. *Boyle.*

Whether any one such body be met with, in those said to be *elemented* bodies, I now question. *Id.*

There is nothing more pernicious to a youth, in he *elements* of painting, than an ignorant master.
*Dryden.*

If dusky spots are varied on his brow,
And streaked with red, a troubled colour show;
That sullen mixture shall at once declare
Winds, rain, and storms, and *elemental* war.
*Dryden's Virgil.*

All rain water contains in it a copious sediment of terrestrial matter, and is not a simple *elementary* water. *Ray.*

They shew that they are out of their *element*, and that logick is none of their talent.
*Baker on Learning.*

The *elementary* salts of animals are not the same as they appear by distillation. *Arbuthnot on Aliments.*

Soft yielding minds to water glide away,
And sip with nymphs their *elemental* tea. *Pope.*

Simple substances are either spirits, which have no manner of composition, or the first principles of bodies, usually called *elements*, of which other bodies are compounded. *Watts.*

First the fine forms her dulcet voice requires,
Which [illegible] in *elemental* flow. *Darwin.*

Peace, heaven-[illegible]nded maid, whose powerful voice
From ancient darkness called the morn;
Of jarring *elements* composed the noise,
When Chaos, from his old dominion torn,
With all his bellowing throng,
Far, far was hurled the void abyss along. *Beattie.*

Elements, in astronomy, are those principles deduced from astronomical observations and calculations, and those fundamental numbers which are employed in the construction of tables of the planetary motions. Thus, the elements of the theory of the sun, or rather of the earth, are his mean motion and eccentricity, and the motion of the aphelia. The elements of the theory of the moon are its mean motion; that of its node and apogee, its eccentricity, the inclination of its orbit to the plane of the ecliptic, &c

Elements, in physics, the first principles of which all bodies in the system of nature are composed These are supposed to be few in number, unchangeable, and by their combinations to produce that extensive variety of objects to be met with in the works of nature. There seems to be in reality some foundation for this doctrine; for there are some principles evidently exempted from every change or decay, but which can be mixed or changed into different forms of matter. A person who surveys the works of nature in an inattentive manner, is apt to form a contrary opinion, when he considers the numerous tribes of fossils, plants, and animals, with the wonderful variety that appears among them in almost every instance. He is thence induced to conclude, that nature employs a vast variety of materials in producing such prodigious diversity. But let him enquire into the origin of this apparent diversity, and he will find that those bodies which seem the most different from each other are at bottom nearly the same. Thus the blood, chyle, milk, urine, &c., as well as the various solid parts of animals, are all composed of one particular substance. The same simplicity appears in the original composition of the nourishment of vegetables, notwithstanding the variety among them with respect to hardness, softness, elasticity, taste, odor, and medical qualities. They chiefly depend, for these, upon water and the light of the sun. Reflections of this kind suggested an idea of several principal elements of which all other bodies are composed, which by their various combinations furnished all the variety of natural bodies. Democritus, Aristotle, and other great philosophers of antiquity, fixed the number to four, which have retained the name of elements ever since. These are, fire, air, earth, and water; each of which they imagined was naturally disposed to hold its own place in the universe. Thus, the earth, as heaviest, naturally tended towards the centre, and occupied the lower parts; the water, as approaching next to it in gravity, was spread chiefly on the outside of the earth; the air, being more subtile and rare, occupied the middle place; while the fire, being still more subtile and active, receded to the greatest distance of all, and was supposed to compose the planets and stars. This system was extended to all the productions of nature. The older chemists, with Paracelsus at their head, pretend to speak of four elementary bodies, salt, sulphur, earth, and mercury: but when we attempt to form an idea of what they mean, we find it very confused; and that their expressions concerning them are enveloped in so much obscurity, that they cannot be comprehended. Some have attempted to prove that the elements, whatever they are, must necessarily be invisible or imperceptible by any of our senses. An enquiry into their number or properties, therefore, must be attended with very little success; and all the knowledge we can have upon the subject must be drawn from a view of their combinations, and reasoning analogically from the transmutations we observe to take place in nature. We find that all the different kinds of air are composed of that invisible and subtile fluid named heat, united in a certain way with some other substance: by which union the compound acquires the properties of gravitation, expansion, rarefaction, &c.; for pure heat, unless when united with some terrestrial substance, neither gravitates nor expands. This is evident from the phenomena of the burning glass, where the light concentrated in the focus will neither heat the air nor water, unless it meets with something with which it can form a permanent union Heat, therefore, is justly to be considered as one of the original elements, being always capable of uniting with bodies, and of being extricated from them unchanged, while the same bodies are by their union with it changed into various forms; water, for instance, into vapor or ice, both of which return into their original state by the abstraction or addition of heat in a certain degree. Hence some have concluded that

there are only two elements in the universe: and this opinion we find adopted by count De Tressan, in his essay on the Electric Fluid. According to this doctrine, two primitive material substances seem to exist in nature; one that incessantly acts, and to which it is essential to be in motion; the other absolutely passive, and whose nature it is to be inert, and move entirely as directed by the former. According to the doctrines which long prevailed among chemists, there are three things that seem to be unchangeable, viz. earth; carbon, or charcoal; and that invisible, though terrestrial and gravitating principle, the basis of chlorine. In our experiments (say the French chemists) on earth, we find that, though vitrified by the most intense fire, it may be recovered in its proper form; and some very pure earths cannot be changed even in the focus of the most powerful mirror. In like manner we may dissipate charcoal in vacuo by the solar rays, and the compound is hydrogenous gas; we may decompose this compound by a metallic calx, and we have our charcoal again unchanged, for all metals contain charcoal in substance. Let us try to destroy it by common fire, and we have it then in the fixed air produced, from which it may be recovered unchanged by the electric spark. With the supposed basis of chlorine, the case is still more difficult, for we cannot by any means procure a sight of it by itself. Modern chemistry reckons fifty-two elements, but as these are only bodies, which the present state of instruments, &c., prevent us from decomposing, their number is continually changing, and we therefore refer the reader to our articles CHEMISTRY, MINERALOGY, &c.

ELEMI, *n. s.*

This drug is improperly called gum *elemi*, being a resin. The genuine *elemi* is brought from Ethiopia in flattish masses, or in cylinders, of a yellowish colour. It is very rare in Europe, and supposed to be produced by a tree of the olive kind. The spurious, or American *elemi*, almost the only kind known, is of a whitish colour, with a greater or less greenish or yellowish tinge. It proceeds from a tall tree, which the Brasilians wound, and collect the resin.
*Hill's Mat. Med.*

ELEMI, a resin, which exudes from incisions made, in dry weather, through the bark of the amyris elemifera, a tree which grows in America. It is wrapped in flag leaves, in long roundish cakes, semitransparent, and of a yellow color. It has a faint fragrance.

ELEMI, in the materia medica. See AMYRIS.

ELENCH, *n. s.* } Old Fr. *elenche*; Lat.
ELENCHIZE, *v. n.* } *elenchus*; Greek, ελεγχος, an argument or sophism. To elenchise used only (as far as we have found), by Ben Jonson, is to argue; construct sophisms.

TIP. Hear him problematize.
PRU. Bless us, what's that!
TIP. Or syllogize, *elenchize*. *Ben Jonson.*

The first delusion Satan put upon Eve, and his whole tentation might be the same *elench* continued, as when he said, Ye shall not die; that was, in his equivocation, you shall not incur present death.
*Browne's Vulgar Errours.*

Discover the fallacies of our common adversary, that old sophister, who puts the most abusive *elenches* on us. *Decay of Piety.*

ELENCHUS, in antiquity a kind of ear rings set with large pearls.

ELENCHUS, in logic, by the Latins called argumentum and inquisitio, is a vicious or fallacious argument, which deceives under the appearance of a truth; the same with what is otherwise called sophism.

ELE'OTS, *n. s.* Some name the apples in request in the cyder countries so; not known by that name in several parts of England.
*Mortimer's Husbandry.*

EL'EPHANT, *n. s.* } Fr. *elephante*, Span.
ELEPHAN'TINE, *adj.* } and Port. *elefante*; Lat. *elephas*; Gr. ελεφας, as Hyde suggests, from Arab. *phil*, a mountain; and Vossius has a similar conjecture. A genus of the mammalia class of animals, more particularly described in the ensuing article.

The *elephant* hath joints, but not for courtesy;
His legs are for necessity, not flexure. *Shakspeare*

High o'er the gate, in *elephant* and gold,
The crowd shall Cæsar's Indian war behold.
*Dryden's Virgil.*

The fan shall flutter in all female hands,
And various fashions learn from various lands;
For this shall *elephants* their ivory shed,
And polished sticks the waving engines spread.
*Gay*

Dear architect of fine chateaux in air,
Worthier to stand for ever if they could,
Than any built of [illegible] wood.
For back of [illegible]

ELEPHANT, in zoology. See ELEPHAS.

ELEPHANT, AMERICAN. See MAMMUTH.

ELEPHANT BEETLE. See SCARABÆUS.

ELEPHANT HOG. See TAPIR.

ELEPHANT, KNIGHTS OF THE, an order of knighthood in Denmark, conferred upon none but persons of the first quality and merit. It is also called the order of St. Mary. Its institution is said to have been owing to a gentleman among the Danish croises having killed an elephant in an expedition against the Saracens in 1184; in memory of which, king Canute instituted this order; the badge of which is a towered elephant, hung on a watered sky-colored riband, like the George in England.

ELEPHANTA, a small but very remarkable island on the west coast of Hindostan, five miles and a half from Bombay, in an easterly direction; its circumference cannot be more than five miles; a neat village near the landing place contains all its inhabitants, who, inclusive of women and children, number about 100. To deduce the era of the fabrication of its celebrated cave or temple is not so easy a task; but it was, no doubt, posterior to the great schism in the Hindu religion, which, according to the Puranas, happened at a period coeval with our date of the birth of Christ. It is under the protection of the India Company, and pays about £56 annually to the government; the surplus revenue furnishes their simple clothing. An elephant of black stone, large as the life, is seen near the landing place, from which the island probably took its name. The cave formed in a hill of stone, is about three-quarters of a mile from the beach; its massy roof is supported by rows of columns regularly disposed, but of an order dif-

ferent from any in use with us; gigantic figures in relief are observed on the walls; these, as well as the columns, are shaped in the solid rock, and by artists, it would appear, possessed of some ability, and unquestionably of astonishing perseverance. They are very massive, short in proportion to their thickness, and their capital bears some resemblance to a round cushion pressed by the superincumbent mountain, with which they are also of one piece. The floor of the apartment is generally full of water, its pavement or ground-work not permitting it to be drawn off, or to be soaked up. For it is to be observed, that even the cavern itself is not visitable after the rains, until the ground of it has had time to dry into a competent hardness. Several of the columns have been levelled, and the figures mutilated, as Mr. Goldingham was informed by the Portuguese, who were at the trouble (and no small one) of dragging cannon up the hill for the better execution of this exploit. The cave at Elephanta is not now in use as a temple, nor is it a place of pilgrimage, or possessed of a sacerdotal establishment; although neighbouring individuals make occasional offerings of prayers and oblations. Considering the pains bestowed on it, it must, at some period of time, have been held in greater estimation; but the brahmins in general disregard imperfect or mutilated images.

Various have been, and are to this day, the conjectures respecting the Elephanta Cave. Those who attempt to deduce its origin from the Egyptians, from the Jews, or from Alexander the Great, appear to give themselves much unnecessary trouble. The striking resemblance in several particulars of the figures in the cave to the present Hindoo race, would induce those who, from history as well as from observation, have reason to believe they have preserved the same customs from time immemorial, to imagine that the ancestors of these people were its fabricators; but those who are in a small degree acquainted with their mythology, will be persuaded of it; nor is a much greater extent of knowledge requisite to enable us to discover it to be a temple dedicated principally to Siva, the destroyer or changer.

ELEPHANTINA, called also Ghezirat-el-Sag, or the 'flowery island,' an island of the Nile, in Upper Egypt, described by captain Light as a perfect paradise. 'It must be confessed that we find beauty by comparison; and this must excuse all travellers in their particular praise of spots, which elsewhere would not, perhaps, call forth their eulogy. Though the season of the year was approaching to the greatest heat, shade was every where to be found amongst the thick plantations of palm trees, which surrounded and traversed the island. Amongst these the modern habitations showed themselves, whilst the eye often rested on the ancient temples still existing. Every spot was cultivated, and every person employed; none asked for money; and I walked about, greeted by all I met with courteous and friendly salams. The intercourse I had with the natives of Assuan was of a very different nature; and in spite of French civilisation and French progeny, which the countenances and complexion of many of the younger part of the inhabitants betrayed, I never received marks of attention without a demand on my generosity.'—*Travels*, pp. 52, 53.

ELEPHANTIASIS, so named from the legs of people affected with this disorder growing rough and wonderfully large, like the legs of an elephant, is a disease that mostly attacks the feet. It is known by the skin being thick, rough, wrinkly, unctuous and void of hair, and mostly without the sense of feeling. It is said to be contagious. Cullen ranks it in the class cachexiæ, and order impetigines. At first very severe pain is felt in one of the inguinal glands, which, after a short time, becomes hard, swelled, and inflamed. No suppuration, however, ensues; but a red streak may be observed running down the thigh from the swelled gland to the leg. As the inflammation increases in all the parts, the fever gradually abates, and perhaps, after two or three days' continuance, goes off. It, however, returns again at uncertain periods, leaving the leg greatly swelled with varicose turgid veins, the skin rough and rugged, and a thickened membrana cellulosa. Scales appear also on the surface, which do not fall off, but are enlarged by the increasing thickness of the membranes; uneven lumps, with deep fissures, are formed, and the leg and foot become at last of an enormous size.

A person may labor under this disease many years; and perhaps the chief inconvenience he will experience is the enormous bulky leg which he drags about with him. The incumbrance has, indeed, induced many to submit to an amputation; but the other leg then frequently becomes affected. See MEDICINE.

ELEPHANTINE, in Roman antiquity, an appellation given to the books wherein were registered the transactions of the senate and magistrates of Rome, of the emperors or generals of armies, and even of the provincial magistrates; the births and classes of the people, and other things relating to the census. They are supposed to have been so called, from the leaves being made of ivory.

ELEPHANTOPUS, in botany, a genus of the polygamia segregata order, and syngenesia class of plants: natural order forty-ninth, compositæ: CAL. quadriflorous, with hermaphrodite florets ligulated or plain; receptacle naked; the pappus bristly. Species six, one an oriental herb, the rest West India plants.

ELEPHAS, the elephant, in zoology, a genus of quadrupeds belonging to the order bruta. The characters, as defined by Linnæus and Gmelin, are these: 'He has no fore teeth in either jaw, and no tusks in the lower jaw; the tusks of the upper jaw are very long, and stretch far out of the mouth: has a long, extensible, and flexible, cartilaginous trunk, or proboscis, on the nose, which is capable of laying hold even of very minute objects. The body is almost naked.' There is only one known species, called by way of distinction from the American elephant, which is quite a different genus, E. maximus, or the great elephant. He is the largest of all land animals. From the front to the origin of the tail he is generally about sixteen feet long, from the end of the trunk twenty-five feet, and about fourteen feet high. The circumference of the legs is about six feet. These are the largest dimensions. But

the animal differs in size in different countries; in some not exceeding seven feet in height. The eyes are small in proportion to the size of the head. The muzzle is very different from that of any other quadruped: it is nothing but the origin of a long trunk which hangs between the two large tusks; the mouth appears behind the trunk, which serves in place of an upper lip, and the under lip terminates in a point. The feet are short, round, clumsy, and only distinguishable by the toes. The trunk is, properly speaking, the nose extended, and terminated by a couple of nostrils. But, besides serving as an organ of smell, the trunk performs all the functions of a strong and dexterous arm. The trunk of an elephant is about eight feet long, five feet and a half in circumference near the mouth, and one foot and a half near the extremity: it is a pipe of an irregular conical figure, and widened at the end: the superior side of the trunk is convex, and furrowed transversely; and the inferior side is flat, and has two longitudinal rows of small protuberances resembling the tentacula of the silkworm and most other caterpillars. The upper part of the trunk corresponds with the extremity of the nose in other quadrupeds, and answers the same intention; the inferior part serves as an upper lip, including the nostrils at the same time. For the trunk is a continued canal, divided into two cavities by a longitudinal partition: these cavities ascend along the fore part of the upper jaw, where they make a turn inward, and descend into the palate, terminating in two separate orifices; they have likewise each a separate orifice at the end of the trunk. At the place where these cavities make a turn, and before they enter into the bones of the head, there is a moveable cartilaginous plate situate in such a manner as enables the animal to shut the canal, and to prevent the water with which it occasionally fills the trunk from entering into the passage of the nose, where the organs serving for the sensation of smell are placed. The elephant can move the trunk in all directions; he can extend or shorten it at pleasure, without altering the diameters of the two canals within. By this means respiration is not interrupted, whatever be the situation of the trunk; and the water is allowed to remain till the animal chooses to throw it out by an expiration. Each canal is lined with a smooth strong membrane, and the surface of the trunk is covered with another strong membrane or skin. The substance contained between the exterior and interior membranes, is a composition of longitudinal and transverse muscles, which serve to extend and contract the length of the trunk. At the extremity of the trunk there is a concave protuberance, in the bottom of which are the two passages of the nostrils. The inferior part of the protuberance is thicker than the sides, and the superior part is stretched out like a finger about five inches long; which, together with the edges of the whole extremity of the trunk, takes on different figures according to the necessities of the animal. It is by this organ that the animal lays hold of food or other substances; and he manages it with as much dexterity as a man does his hand, taking up grains of corn, or the smallest piles of grass, and conveying them to his mouth. When he drinks, he thrusts his trunk into the water, and fills it by drawing in his breath and exhausting the air: when the trunk is thus filled with water, he can either throw it out to a great distance, or drink it by putting the end of the trunk in his mouth. The two large tusks, which some call the horns, of the elephant, are of a yellowish color, and extremely hard. The bony substance of which they are composed is known by the name of ivory, and much used in different branches of manufacture. The ears are very large, and resemble those of an ape. The skin of the elephant has but few hairs on it, placed at great distances from each other. It is full of wrinkles, like those on the palm of a man's hand, besides many chapped and greasy ridges. The female has two dugs, one on each side of the breast.

The female elephant has not, like other quadrupeds, the orifice of the vagina adjacent to the anus; for it is situated nearly in the middle of the belly, about two and a half or three feet distant from the anus. Naturalists, as well as travellers, agree in affirming that the male organ of the elephant exceeds not either in length or diameter that of a horse. Although, for this reason, Buffon, Linnæus, and other eminent writers, have made their coition a subject of considerable controversy, yet, as they have since been observed to cover like the horse, the subject is not worth pursuing. As to the time of gestation, which Buffon limits to nine months, the best modern authorities consider it to be about twenty months. They bring forth but one at a time; which, on coming into the world, is as large as a wild boar, and is furnished with teeth: however, the large tusks do not make their appearance till some time after, and at the age of six months they are several inches long. Elephants of this age are as large as an ox in a natural state.

Elephants, even in a savage state, are peaceable and gentle creatures. They never use their weapons but in defence of themselves or their companions. Their social dispositions are so strong, that they are seldom found alone, but march always in large troops: the oldest and most experienced lead the van; the young and the lame keep in the middle; and those of the middle age walk in the rear. The females carry their young on their tusks, embracing them at the same time with their trunk. They seldom march in this regular order but when they reckon the journey dangerous, such as an expedition to cultivated lands, where they expect to meet with resistance. On other occasions they are less cautious; some of them falling behind or separating from the rest, but seldom so far as to be beyond the reach of assistance from their companions. It is dangerous to offer them the least injury; for they run straight upon the offender; and, though the weight of their body be great, their steps are so large, that they easily outrun the swiftest man, whom they either pierce with their tusks, or seize with their trunk, dart him in the air, and then trample him under their feet. Travellers who frequent these countries kindle large fires, and beat drums during the night, to prevent their approach. After being once attacked by men, or falling into any ambush, they never forget the in-

jury, but search for every opportunity of revenge. As they are probably endowed with a more exquisite sensation of smell than any other animal, owing to the great extent of their nose, they can scent a man at a very great distance, and trace him by his footsteps. Elephants are peculiarly fond of the banks of rivers, deep valleys, and marshy grounds, especially when well shaded with trees. They delight in drawing up water into their trunks, even when they do not drink it, and amuse themselves in dashing it around. They cannot endure cold, and are equally averse to heat. To avoid the scorching sun, they retire to the thickest and most shady parts of the forest. The bulk of their bodies is so enormous, that they do not choose to go into deep waters so frequently as some other quadrupeds; although the length of their trunk, which they can raise straight up to respire, is a great advantage in swimming. Their ordinary food is roots, herbs, leaves, the tender branches of trees, fruits, and grains; but they abhor flesh or fish. As they devour a large quantity of food in a short time, they often shift their pasture; when they meet with cultivated grounds, they make a prodigious desolation, and destroy more plants by their feet than they use for nourishment; which last is very considerable, amounting to 150 pounds of herbage every day: by this means, as they constantly graze in large troops, they lay waste whole fields in an hour. The Indians and negroes employ every art to prevent them from visiting their cultivated lands, making great noises, and burning large fires round their fields. However, these precautions are not always sufficient to prevent the elephants from visiting them. They chase away the domestic animals, put the men to flight, and sometimes even throw down their habitations. Elephants are hardly susceptible of fear: the only method to stop their course is by fire or fireworks, the effects of which being sudden and quickly repeated, the elephants frequently turn back; and, when one runs, all the rest instantly follow him.

In Ceylon, where these noble animals principally abound, a considerable trade is carried on in live elephants. They are caught in various snares, and then exported to different parts of India, where they fetch a considerable price. 'At Gannitherê,' says Dr. Davy, in his interesting work on Ceylon, 'close to the foot of the mountain, we went off the road about half a mile over paddy-fields, to visit an elephant snare, situated in a narrow part of the valley. The snare is merely a square space of small dimensions surrounded by strong palisades, having a tree in the middle and one narrow entrance. The manner in which elephants are here taken is very simple. The wild animals are first driven to Kandy, and then, if approved of, to this place. When an elephant enters the enclosure, he is fastened to the tree by means of a noose, and his feet are properly secured by strong ropes. From the enclosure he is led to an adjoining spot; a shed is built over him; his feet are tied firmly to the trees, and he is not allowed to lie down. We found six elephants in progress of taming—their limbs more or less shackled, according to the subjugation effected. They were all extremely lean, and miserable objects to look at. More than half of those caught, die during their confinement: they seem to pine for the lost blessing of liberty; they refuse to eat, and generally die of starvation. If they can be prevailed on to take food, the difficulty of the task is got over, and they are soon tamed. Great as the mortality is in this instance, it is small in proportion to that which takes place in a large snare, such as is used in the low country.'

Our author then refers to the following account of the large snare used in the low and maritime countries, in Mr. Cordiner's Travels in Ceylon. The hunt alluded to took place near the elephant snare at Kotaway, only a few miles distant from Tengalle. The governor and his suite attended on this occasion, and the whole of the party employed was not fewer than 3000 persons. The whole of this multitude surrounded the forests in which elephants are discovered to abound, with a chain of fires placed on moveable stands, so as to be brought closer, according as the elephants are driven nearer to the centre. The distance between the fires may at first have been 100 paces, which is gradually reduced to about ten paces. The more the elephants are confined, the more vigilant the hunters must become, and prepared to repel their efforts to escape, by advancing the fires, and by loud shouting. At the end of two months, they thus become enclosed in a circle, of which the wide entrance of the snare forms a part, and are at last brought so near to it, that, by the exertions of the surrounding multitude, they can be made close prisoners in a few hours. It is now that all those who are desirous of witnessing the capture resort to the scene of action.

An idea of the enclosure may be formed by drawing, on a piece of paper, the outline of a wide funnel. A little way within the wide end, a palisade runs across, in breadth 600 feet, containing four open gates, at which the elephants enter. A view of two of these is commanded from a bungaloe, erected for spectators on pillars thirty feet from the ground. The enclosure is formed of the strongest trees on the island, from eight to ten inches in diameter, bending inwards, sunk four feet into the ground, and from sixteen to twenty feet high above it. They are placed at the distance of sixteen inches from each other, and crossed by four rows of powerful beams, bound fast to them with pliant canes. To this palisade are added supporters more inclined, several feet asunder, augmenting the strength of the fence. The part of it in which the elephants are first enclosed is 1800 feet in circumference: but it communicates with a smaller fold, 100 feet in length, and forty broad, through which a rivulet passes, five feet in depth, and nearly fills the enclosure. The elephants enter this place of confinement at only one gate; and beyond the water the fence gradually contracts, terminating in a strong passage, five feet broad, and 100 feet long.

When the first enclosure is completely stocked, the four gates are closed and secured with strong stakes. Then another chain of fires and torches is formed within the enclosure, and the persecuted animals are driven forward in like manner into the smaller fold.

'At sunrise,' continues Mr. Cordiner, 'we became spectators of a most extraordinary sight. So great a number of enormous animals crowded into so small a compass, is a spectacle rarely to be seen. Pressing heavily upon one another, incapable of almost any movement but convulsions of distress, their paroxysms of anguish could not be contemplated without emotion. No person could find language to express his feelings. All were struck dumb with a species of astonishment hitherto unexperienced. The most hazardous part of the business remains, that of seizing on the elephants at the end of the long passage, which is the only outlet from the water snare. They are driven in one by one, making furious efforts to regain their liberty on finding themselves prisoners. When they reach the gate at the end, strong beams are inserted across the passage behind, to prevent them from retreating. Men then approach, and bind their hind legs with great ropes, and five or six turns of smaller cordage are passed round their necks. While these operations are going on, a man stands before the gate of the passage, tickling the elephant's trunk, and diverting his attention. In this manner they are secured, yet accidents frequently happen at this time. On the present occasion, one unfortunate man tumbled into the passage, and was instantly trampled to death under the feet of an enraged elephant. They frequently press against one another in the water snare and the passage with so much violence, that some are squeezed to death, or drop down dead with fatigue.'

When the wild elephant is completely harnessed, two tame elephants, trained to the business, are brought to the gate, and placed one on each side of it. These immediately survey the prisoner whom they have to conduct, feel his mouth to know whether or not he has tusks, and lay hold of his proboscis to ascertain what degree of resistance he is likely to make. Ropes are passed through the collar of the wild elephant, and made fast to similar collars on each side of the tame ones. The bars of the gate are then unloosed, and drawn out; and the wild captive darts forward directly between the two tame elephants: he can, however, only advance a little way, as the ropes securing his hind legs still continue fastened to the strong stakes of the toil. In this situation he remains, until the riders mounted on the tame elephants have drawn tight the cords, which bind him to the necks of his half-reasoning conductors.

During this operation, he endeavours to undo with his trunk some of the knots which have been made, and often attempts to give a destructive blow to the diminutive creatures so actively engaged in confirming his captivity. But the two tame animals, who are vigilantly observant of all his motions, never fail to prevent him from doing any mischief, by gently lowering his proboscis with their own: if he continue long refractory, they batter him with their heads, and at last produce the most obsequious submission. The nooses of the ropes are then opened, leaving his hind legs at freedom, and himself entirely disengaged from the snare. The two tame elephants press close on each side of him, and proceed, in pompous procession, to the garden of stalls, where they deliver up their charge to experience another species of hardships. The marching off of this venerable trio is a sight truly magnificent, and exhibits a noble specimen of the skill of man, united with the sagacity of the elephant.

In this manner the prisoner is conducted to a grove, where, if he is of an ordinary size, he is sufficiently secured by being placed lengthwise between two trees, to one of which his hind legs are bound, and one of his fore legs to the other. A more complicated apparatus of ropes and stakes is necessary for those which are remarkable for strength and fury. The tame conductors then move away to secure another captive. An elephant may frequently be tamed in eight or ten days, though in other instances, months are required. When tamed, they are marched round to Jaffnapatam, there sold by public auction, and thence exported to the opposite continent.

The elephant, when tamed, is the most friendly and obedient of all animals: he is entirely attached to the person who feeds and takes care of him. In a short time he understands signs, and the sound of his master's voice. He distinguishes the language of passion, of command, of satisfaction, and acts accordingly. He receives his orders with attention, and executes them with alacrity, but without precipitation. He easily learns to bow his knees and lower his body, for the convenience of those who mount him He lifts burdens with his trunk, and assists those who are loading him in laying them on his back. He delights in shining harness and trappings. When yoked in a cart or waggon, he pulls equally and cheerfully, unless he be abused by injudicious chastisements. His guide is generally mounted on his neck, with a small rod of iron, sharp at the point, in his hand; he directs his motion by pricking him on the ears and head; but for the most part a word is sufficient A tame elephant will do more labor than six horses, but he requires a proportional quantity of food. They are the principal beasts of burden in many parts of Africa and the East Indies. They carry sacks and bundles of all kinds on their necks, backs, and tusks. They seldom lose or damage any thing committed to their care: they will stand on the edge of a river, take bundles off their necks and tusks, lay them carefully in a boat wherever they are desired, and try with their trunk whether they are properly situated; if they be loaded with casks they go in quest of stones to prop them and prevent them from rolling. When the elephant is properly managed he lives very long, even in a state of slavery and labor. That some have lived in this state 130 years is pretty well authenticated. In a natural state they often exceed 200 years, and propagate their species till they are 120: It is thirty years before they come to their full growth. The elephants inhabit India, and some of its greater islands, Cochin China, and some of the provinces of China. They abound in the southern parts of Africa, from the river Senegal to the Cape; and from thence as high as Ethiopia on the other side. They are found in the greatest numbers in the interior parts, where there are

vast forests, near the sides of rivers. The wild elephants of Ceylon live in troops or families, distinct and separate from all others, and seem o avoid the strange herds with peculiar care. When a family removes from place to place, the largest tusked males put themselves at the head, and if they meet with a large river are the first to pass it. On arriving on the opposite bank they try whether the landing place is safe: if it be, they give a signal of a note from the trunk as if it were the sound of a trumpet, on which the remaining part of the old elephants swim over; the little elephants follow, holding one another by locking their trunks together, and the rest of the old ones bring up the rear. In the woods is often seen a solitary male elephant, wandering like an outlaw, banished from the herd and all the race. In this solitary state, as if in a state of desperation, they are very dangerous. A single man will put to flight whole herds of social elephants: the solitary one fears not his presence, but will stand firm, putting his power to defiance. Elephants are not domesticated in Africa as in the more civilised parts of Asia, although they are much more numerous. In some parts of Africa they swarm so, that the negroes are obliged to make their habitations under ground for fear of them. They are killed and eaten by the natives, and the trunk is said to be a delicious morsel. In the Philosophical Transactions for 1799, we find some curious particulars relative to the natural history of the elephant, by Mr. Corse, who, during his residence in India, had investigated the subject with considerable attention. A female elephant has been known to forget her young one in the short space of two days' separation, and to repel its advances. It is also said, that an elephant which had escaped from its confinement suffered itself to be again trepanned, and reconducted to its state of captivity. According to Mr. Corse, both male and female elephants are divided by the natives of Bengal into two castes, viz. koomareah and the merghee; the former consisting of the large or full bodied kind; the latter of the more slender, with longer legs and proportionably thinner trunk. The merghee is also a taller animal than the koomareah, but not so strong. Many indistinct varieties are again produced from the intermixture of these two breeds. A large trunk is always considered as a great beauty in an elephant, so that the koomareah is always preferred, not only on this account, but for his superior strength in carrying burdens, &c. The torrid zone appears to be the natural clime of the elephant, and the most favorable for the production of the largest and hardiest race; and, when this animal migrates beyond the tropics, the species degenerates. Elephants are taken on the Malabar coast, as far north as the territories of Coorgah Rajah, but these are considered by Mr. Corse as much inferior to the Ceylonese elephant. In some female elephants the tusks are so small as not to appear beyond the lip, whilst in others they are large and long. In both sexes the grinders are very much alike. The largest tusks, and those which furnish the best ivory, are found in a variety of the male elephant, called dauntelah, from this circumstance, in opposition to another called mooknah, whose tusks do not exceed those of some females. An elephant is considered perfect when his ears are large and rounded, not ragged or indented at the margin: his eyes of a dark hazel color, free from specks: the roof of his mouth and his tongue without dark or blackish spots of any considerable size: his trunk large: his tail long, with a tuft of hair hanging almost to the ground. His fore-feet must have five nails on each, and the hinder ones four; his head well set on and carried rather high: the arch or curve of his back rising gradually from the shoulder to the middle, and thence descending to the insertion of the tail. All his joints must be firm and strong. In one variety of the elephant the tusks point downwards, projecting only a little way beyond the trunk. The tusks in elephants are fixed very deep in the upper jaw; and the root or upper part, which is hollow, and filled with a core, goes as high as the insertion of the trunk, round the margin of the nasal opening of the throat, which opening is just below the protuberance of the forehead.

The elephant breathes through this opening, and by its means sucks up water into his trunk: between it and the roots of the tusks there is only a thin bony plate. The first or milk tusks of an elephant are shed between the first and second year, when scarcely two inches in length. The time when the tusks cut the gums varies considerably; some young elephants have tusks at five months, and others not till seven; yet these deciduous tusks are formed in a fœtus arrived at its full time. A young elephant was observed to shed one of its milk tusks, on the 6th of November, 1790, when only about thirteen weeks old, and the other on the 6th of December the same year: about two months after, the permanent ones cut the gums; and on the 19th of April, 1791, they were an inch long. Another young elephant was sixteen months before he shed his milk tusks; so various is the time of this process. The permanent tusks of the female are small, compared with those of the male; and do not take their rise so deep in the jaw. The tusks are increased by layers of ivory arising internally from the core on which they are formed; similar to the growth of the horns of some animals. The largest elephant tusks Mr. Corse ever saw, in Bengal, did not exceed the weight of 72 lbs. avoirdupois: at Tiperah, they seldom weigh more than 52 lbs. each. But those brought from other parts to the India-house, far exceed either of these weights, some of them weighing 150 lbs. each. Mr. Corse supposes these to come from Pegu. The Asiatic elephant is said to be larger than the African; yet the ivory dealers in London affirm that the largest tusks come from Africa; and that they are of a better texture, and less liable to turn yellow than the Indian ones. From the earliest accounts in history, the eastern nations have employed elephants in war; Alexander the Great was the first European who ever mounted an elephant. He carried a number of them into Greece, which Pyrrhus employed some years after against the Romans at the battle of Tarentum. Both the Greeks and Romans soon learnt to get the better of those monstrous animals: they opened their ranks and

allowed them to pass through; neither did they attempt to hurt them, but threw darts, &c., at their guides. Now that fire-arms are the principal instruments of war, elephants, who are terrified at the noise and flame, instead of being useful, would only embarrass and confuse an army. However, in Cochin and other parts of Malabar, and in Tonquin, Siam, and Pegu, where fire-arms are little understood, they are still used in battle. The guide sits astride upon the neck, and the combatants sit or stand upon the other parts of the body. They are also extremely serviceable in fording rivers, and carrying over the baggage on their backs. After the keepers have loaded them with several hundred weight, they fasten ropes to them; of which the soldiers taking hold, either swim or are drawn across the river. In time of action, they sometimes fix a heavy iron chain to the end of their trunks, which they whirl round with such agility, as to make it impossible for an enemy to approach them at that time. Another use they still have for this creature in war, is to force open the gates of a city or garrison which is closely besieged. This he does by forcing himself against them with his whole weight, till he has burst the bars: to prevent which, most of the garrisons in this country have large spikes stuck in their gates, that project to a considerable distance. But these prodigious animals are kept more for show and grandeur than for use, and their keeping is attended with a very great expense; for they devour vast quantities of provision, and must sometimes be regaled with a plentiful repast of cinnamon, of which they are excessively fond. It is said to be no uncommon thing with a Nabob, if he has a mind to ruin a private gentleman, to make him a present of an elephant, which he is ever afterwards obliged to maintain at a greater expense than he can afford: as, by parting with it, he would certainly fall under the displeasure of the grandee, besides forfeiting all the honor which his countrymen think is conferred upon him by so respectable a present.

EL'EVATE, *v. a.* & *part. adj.*
ELEVA'TION, *n. s.*
EL'EVATOR.
} Fr. *elever*; Span. *elevar*; Port. *alavantar*: Ital. and Lat. *elevare*; from *levis*, light, i.e. easily lifted. To lift up; also to make light; lessen by detraction. For the particular use of elevation, see the article following.

When the judgments of learned men are alledged against you, what do they but either *elevate* their credit, or oppose unto them the judgments of others as learned? *Hooker.*

All which different *elevations* of spirit unto God are contained in the name of prayer. *Id.*

His style was an elegant perspicuity, rich of phrase, but seldom any bold metaphors; and so far from tumid, that it rather wanted a little *elevation*. *Wotton.*

To mischief swift, hope *elevates*, and joy
Brightens his crest. *Milton.*

On each side an imperial city stood,
With towers and temples proudly *elevate*
On seven small hills. *Id.*

Some latitudes have no canicular days, as those which have more than seventy-three degrees of northern *elevation*, as Nova Zembla.
*Browne's Vulgar Errours.*

Where the hand is used to the plough and the spade, the head is seldom *elevated* to sublime notions, or exercised in mysterious reasoning. *Locke.*

Angels, in their several degrees of *elevation* above us, may be endowed with more comprehensive faculties. *Id.*

We are therefore to love him with all possible application and *elevation* of spirit, with all the heart, soul, and mind. *Norris.*

This subterranean heat or fire, which *elevates* the water out of the abyss. *Woodward.*

The disruption of the strata, the *elevation* of some, and depression of others, did not fall out by chance, but were directed by a discerning principle. *Id.*

Those among the nobles who wished for a reformation in religion, dreaded his severity, and others considered the *elevation* of a churchman to the highest office in the kingdom as a depression of themselves.
*Robertson. History of Scotland.*

Kings are naturally lovers of low company. They are so *elevated* above the rest of mankind, that they must look upon all their subjects as on a level.
*Burke.*

The *elevation* of the mind ought to be the principal end of all our studies, which, if they do not in some measure effect, they are of very little service to us.
*Id.*

Some headless hero, or some Cæsar, shows—
Defective only in his Roman nose;
Exhibits *elevations*, drawings, plans,
Models of Herculanean pots and pans;
And sells them medals, which, if neither rare
Nor ancient, will be so, preserved with care.
*Cowper.*

ELEVATION OF THE HOST, in the church of Rome, that part of the mass where the priest raises the host above his head for the people to adore.

ELEVATOR, in anatomy, the name of several muscles, so called from their serving to raise the parts of the body to which they belong.

ELEVATOR, in surgery, an instrument for raising depressed portions of the skull. Besides the common elevator, several others have been invented, as, for instance, the tripod elevator, and another, which was first devised by M. I. L. Petit, and afterwards improved by M. Louis: but as all the best modern surgeons give the preference to the common one, which is most simple and is found to answer every desirable purpose, we shall not undertake the description of these more complicated instruments. The common elevator is in fact a mere lever, the end of which is somewhat bent, and made rough, in order that it may be less apt to slip away from the piece of bone which is to be raised. This instrument may be used by forming a fulcrum for it, either in the hand which holds it, or on the fingers of the other hand; or the operator may make a fixed point for it on the edge of the opening made with the trephine, or of that which the accidental violence has occasioned. See TREPANNING.

ELEV'EN, *adj.*
ELEV'ENTH.
} Sax. ænleꝼen (æn, one, and lyꝼan, to leave), one left, i. e. above ten, or after the enumeration of ten, as Skinner suggests. See TWELVE.

And thei bithoughten on his wordis, and thei geden agen fro the graue; and teelden alle these thingis to the *ellevene* and to alle othere.
*Wiclif. Luk* 24.

Had I a dozen sons, and none less dear than Marcius, I had rather *eleven* die nobly for their country, than one voluptuously forfeit out of action.
*Shakspeare.*

In the *eleventh* chapter he returns to speak of the building of Babel. *Raleigh's History.*

I know not wherein Lewis the *Eleventh* shewed himself unwitty, but in the charge which he gave to his son, to learn no more Latin. *Bp. Hall.*

ELEUSINIA, in Grecian antiquity, a festival held in honor of Ceres, every fourth year by some states; by others every fifth. The Athenians celebrated it at Eleusis, whence the name. Here stood the memorials of her presence and of her bounty; the well, Callichorus, by which she had rested, in the reign of Erectheus; the stone on which she sat, named the sorrowful; the Rharian plain, where barley was first sown; and the threshing floor and altar of Triptolemus, a herdsman whom she instructed in the culture of that grain, the use of which succeeded to acorns. The mystic temple, provided by Pericles for the solemnity, was unequalled for beauty and magnitude. The profane or uninitiated were forbidden to enter it on any pretence; and any intrusion was punished with death. The chief priest, Ιεροφάντης, was taken from the Eumolpidæ, a holy family at Athens, descended from Eumolpus, a shepherd and favorite of Ceres. He was enjoined celibacy, and wore a long garment, and a wreath of myrtle. Under him, besides many of inferior station, was the torchbearer, δαδόυχος, who had likewise his hair bound with a fillet; the priest, who officiated at the altar, thence called ο επι βωμῶ; and the sacred herald, Κηρυξ. The latter was of a family which claimed the god Mercury and Aglauros the daughter of Cecrops for its ancestors. The secrecy in which the mysteries were enveloped was so strict, that no person was allowed even to name the hierophant by whom he had been initiated. Public abhorrence and detestation awaited the babbler, and the law condemned him to death. The Athenians at first suffered none but citizens to be initiated into these mysteries. This regulation, which compelled Hercules, Castor, and Pollux, to become citizens of Athens, was strictly observed in the first ages of the institution, but afterwards all persons, barbarians excepted, were freely initiated. The Eleusinia were divided into the greater and lesser mysteries. Μυστήρια μεγάλα και μικρά. The lesser were instituted from the following circumstances:—Hercules passed near Eleusis while the Athenians were celebrating the mysteries, and desired to be initiated. As this could not be done, because he was a stranger, and as Eumolpus was unwilling to displease him on account of his great power, and the services which he had done to the Athenians, another festival was instituted, and Hercules was solemnly admitted to the celebration and initiated. In later times the smaller festivals were preparatory to the greater, and no person could be initiated at Eleusis without a previous purification at Agræ. This purification they performed by keeping themselves pure, chaste, and unpolluted, during nine days; after which they came and offered sacrifices and prayers, wearing garlands of flowers, called, ισμερα or ιμερα, and having under their feet Διος κωδιον, Jupiter's skin, which was the skin of a victim offered to that god. The person who assisted was called ὑδρανος, from υδωρ water, which was used at the purification, and they themselves were called μυσται, the initiated. A year after the initiation at the less mysteries they sacrificed a sow to Ceres, and were admitted in the greater, and the secrets of the festivals were solemnly revealed to them, from which they were called εφοροι and εποπται, inspectors. This festival was observed in the month Boedromion or September, and continued nine days from the 15th till the 23rd. During that time it was unlawful to arrest any man or present any petition, on pain of forfeiting 1000 drachmas, or, according to others, on pain of death. If any woman rode to Eleusis in a chariot, she was obliged by an edict of Lycurgus to pay 6000 drachmas. The design of this law was to destroy all distinction between the rich and poor citizens. When the season approached, the mystæ, or persons who had been initiated only in the lesser mysteries, repaired to Eleusis to be instructed in the ceremonial. The first day was called αγορμος, an assembly, because the mystæ then first assembled together. The service for the opening of the temple, with morning sacrifice, was performed. The ritual, which was called Petroma,* and consisted of two stones exactly fitted, was then produced. The mysterious record was replaced after the reading, and closed up until a future festival. The principal rite was nocturnal, and confined to the temple and its environs. The mystæ waited without, with impatience and apprehension. Lamentations and strange noises were heard. Flashes of light and of fire rendered the deep succeeding darkness more terrible. They were beaten, and perceived not the hand. They beheld frightful apparitions, monsters, and phantoms of a canine form. They were filled with terror, became perplexed and unable to stir. The scene then suddenly changed. The propylæa or vestibules of the temple were opened and the curtains withdrawn. They were introduced by the hierophant and daduchus, and the former showed them the mysteries. The splendor of the illumination, the glory of the temple and of the images, the singing and dancing which accompanied the exhibition, all contributed to sooth the mind after its late agitation, and to astonish the wondering devotee. After this inspection, called αυτοψια, they retired, and others advanced. The succeeding days were employed in purification, in sacrifice, in pompous processions, and spectacles, at which they assisted, wearing myrtle crowns. The second day was called αλαδε μυσται, i. e. to the sea, you that are initiated; because they were commanded to purify themselves by bathing in the sea. On the third day sacrifices, and chiefly a mullet, were offered; also barley from a field of Eleusis. These oblations were called Θυα, and held so sacred that the priests themselves were not permitted to partake of them. On the fourth day they made a solemn procession, in which the καλαθιον, or holy basket of Ceres, was carried about in a consecrated cart, while on every side

the people shouted χαιρε Δημητερ, Hail Ceres! After these followed women called κιστοφοροι, who carried baskets, in which were sesamum, carded wool, grains of salt, a serpent, pomegranates, reeds, ivy boughs, certain cakes, &c. The fifth was called Ἡ των λαμπαδων ημερα, the torch day; because on the following night the people ran about with torches in their hands. It was usual to dedicate torches to Ceres, and contend who should offer the biggest, in commemoration of the travels of the goddess, and of her lighting a torch in the flames of mount Ætna. The sixth day was called Ιακχος, from Iacchus, the son of Jupiter and Ceres, who accompanied his mother in her search after Proserpine, with a torch in his hand. From that circumstance his statue had a torch in his hand, and was carried in solemn procession from the Ceramicus to Eleusis. The statue, with those that accompanied it, called Ιακχαγωγοι, was crowned with myrtle. In the way nothing was heard but singing and the noise of brazen kettles as the votaries danced along. The way through which they issued from the city was called Ιερα οδος, the sacred way; the resting place was Ιερα συκη, from a fig-tree, which grew in the neighbourhood. They also stopped on a bridge over the Cephisus, where they derided those that passed by. After they had passed this bridge, they entered Eleusis by a place called μυστικη εισοδος, the mystical entrance. On the seventh day there were sports, in which the victors were rewarded with a measure of barley, as that grain had been first sown in Eleusis. The eighth day was called Επιδαυριων ημερα, because once Æsculapius at his return from Epidaurus to Athens was initiated by the repetition of the less mysteries. It became customary, therefore, to celebrate them a second time upon this, that such as had not hitherto been initiated might be lawfully admitted. The ninth and last day of the festival was called Πλημοχοαι, earthen vessels, because it was usual to fill two such vessels with wine; one placed towards the east, and the other towards the west, which, after the repetition of some mystical words, were both thrown down, and the wine being spilt on the ground was offered as a libation. The story of Ceres and Proserpine, the foundation of the Eleusinian mysteries, was partly verbally delivered, and partly represented in allegorical show. Proserpine was gathering flowers when she was stolen by Pluto. Hence the procession of the holy basket, which was placed on a car dragged along by oxen, and followed by a train of females, some carrying the mystic chests, shouting, Hail, Ceres! At night a procession was made with lighted torches, to commemorate the goddess searching for her daughter. A measure of barley, the grain which it was believed she had given, was the reward of the victors in the gymnastic exercises; and the transaction at the temple had a reference to the legend. Some, however, have supposed the principal rites at this festival to have been obscene and abominable, and that thence proceeded all the mysterious secrecy. They were carried from Eleusis to Rome in the reign of Adrian, where they were observed with the same ceremonies as before, though perhaps with more licentiousness. They lasted about 1800 years, and were at last abolished by the emperor Theodosius.

ELEUSIS, the modern Lefchimo, was, in ancient geography, a town of Attica, between Megara and the Piræus, and celebrated for the festivals of Ceres; rites not finally extinguished in Greece until the invasion of Alaric the Goth. Eleusis, on the overthrow of its goddesses and the cessation of its mysteries, became soon an obscure place, without character or riches. For some ages, however, it was not entirely forsaken. The port was small and of a circular form; the stones of one pier were seen by Chandler above water, and the corresponding side was traced. About half a mile from the shore he found a long hill which divided the plain. In the side next the sea were traces of a theatre, and on the top cisterns cut in the rock. In the way to it some masses of wall and rubbish, partly ancient, were standing, he says; and beyond some other ruins a long broken aqueduct crossed to the mountains. The Christian pirates had infested the place so much, that in 1676 it was abandoned. It is now a small village at the eastern extremity of the rocky brow, on which was once a castle, and is inhabited by a few Albanian families, employed in the culture of the plain. The mystic temple at Eleusis was planned by Ictinus, the architect of the Parthenon. Pericles was overseer of the building. It was of the Doric order; the cell so large as to admit the company of a theatre. The columns on the pavement within, and their capitals, were raised by Coræbus. Metagenes, of Xypete, added the architraves and the pillars above them, which sustained the roof. Another completed the edifice. This was a temple in antis, or without exterior columns, which would have occupied the room required for the victims. The aspect was changed to Prostylos, under Demetrius, the Phalerian; Philo, a famous architect, erecting a portico, which gave dignity to the fabric, and rendered the entrance more commodious. The site was beneath the brow, at the east end, and encompassed by the fortress. Some marbles, which are uncommonly massive, and some pieces of the columns, remain on the spot. The breadth of the cell is about 150 feet; the length, including the pronaos and portico, is 216 feet; the diameter of the columns, which are fluted six inches from the bottom of the shafts, is six feet and more than six inches. The temple was a decastyle, or had ten columns in the front, which was to the east. The peribolus, or enclosure, which surrounded it on the north-east and on the south side, measures 387 feet in length from north to south, and 328 feet in breadth from east to west. On the west side it joined the angles of the west end of the temple in a straight line. Between the west wall of the enclosure and temple and the wall of the citadel was a passage of forty-two feet six inches wide, which led to the summit of a high rock at the north-west angle of the enclosure, on which are visible the traces of a temple in antis, in length seventy-four feet six inches from north to south, and in breadth from the east to the wall of the citadel, to which it joined on the west, fifty-four feet. It was perhaps that sacred to Triptolemus.

This spot commands a very extensive view of the plain and bay. About three-fourths of the cottages are within the precincts of the mystic temple, and the square tower stands on the ruined wall of the enclosure. At a small distance from the north end of the enclosure is a heap of marble, consisting of fragments of the Doric and Ionic orders, remains, it is likely, of the temples of Diana Propylea and of Neptune, and of the Propyleum or gateway. Wheeler saw some large stones carved with wheat ears and bundles of poppy. Near it is the bust of a colossal statue of excellent workmanship, maimed, and the face disfigured; the breadth at the shoulders, as measured by Pococke, five feet and a half; and the basket on the head above two feet deep. It probably represented Proserpine. In the heap are two or three inscribed pedestals; and on one are a couple of torches, crossed. Another cross seems to have belonged to the statue of a lady, who was hierophant or priestess of Proserpine, and had covered the altar of the goddess with silver. A well in the village was perhaps that called Callichorus, where the women of Eleusis were accustomed to dance in honor of Ceres. A tradition prevails, that, if the broken statue be removed, the fertility of the land will cease. The modern town does not contain more than thirty houses.

ELEUTHERIA, a festival, celebrated at Platæa, in honor of Jupiter Eleutherius, or the assertor of liberty, by delegates from almost all the cities of Greece. Its institution originated in this:—After the victory obtained by the Grecians, under Pausanias, over Mardonius the Persian general, in Platæa, an altar and statue were erected to Jupiter Eleutherius, who had freed the Greeks from the tyranny of the barbarians. It was further agreed upon in a general assembly, by the advice of Aristides, the Athenian, that deputies should be sent every fifth year, from the different cities of Greece, to celebrate Eleutheria, festivals of liberty. The Platæans celebrated also an anniversary festival in memory of those who had lost their lives in that famous battle on the sixteenth of the month Mæmacterion, a procession was made with a trumpeter at the head, sounding a signal for battle. After him followed chariots loaded with myrrh, garlands, and a black bull, and certain free young men, as no signs of servility were to appear during the solemnity, because they in whose honor the festival was instituted had died in the defence of their country. They carried libations of wine and milk in large-eared vessels, with jars of oil, and precious ointments. Last of all appeared the chief magistrate, who, though not permitted at other times to touch iron, or wear garments of any color but white, yet appeared clad in purple, and, taking a water pot out of the city chamber, proceeded through the middle of the town, with a sword in his hand, towards the sepulchres. There he drew water from a neighbouring spring, and washed and anointed the monuments, after which he sacrificed a bull upon a pile of wood, invoking Jupiter and infernal Mercury, and inviting to the entertainment the souls of those happy heroes who had perished in the defence of their country. After this he filled a bowl with wine, saying, I drink to those who lost their lives in the defence of the liberties of Greece. There was also a festival of the same name observed by the Samians in honor of the god of love. Slaves also, when they obtained their liberty, kept a holiday, which they called eleutheria.

ELF, *n. s.* & *v. a.*
ELF'IN, *n. s.* & *adj.*
ELF'ISH, *adj.*
ELF'-LOCK, *n. s.*
ELF'-QUEEN,
EL'VISH, *adj.*

Sax. ælfe; Goth. and Teut. *alf*; Swed. *alf-war*; Brit. *eilf*; Belg. *alve*; à Gr. επιαλτης or εφίαλτης, says Minsheu, incubus, the night-mare. Skinner derives the Saxon word from ahleopan, Saxon, to leap. The male of a fairy; a spirit of the woods or mountains; a demon; a dwarf. To elf is to entangle or ravel the hair as elves were supposed to do; and elf-locks are hair so ravelled. Elfin is a diminutive of elf; or, as an adjective, synonymous with elfish, and signifies of or belonging to elves.

In olde dayes of the King Artour,
Of which that Bretons spoken gret honour
All was this lond fulfilled of Faerie;
The *Elf*-quene with hire joly compagni
Danced ful oft in many a grene mede.
*Chaucer. Cant. Tales.*

Now when that idle dream was to him brought,
Unto that *elfin* knight he bade him fly,
Where he slept soundly. *Spenser.*

Through this house give glimmering light,
By the dead and drowsy fire;
Every *elf*, and fairy sprite,
Hop as light as bird from briar. *Shakspeare.*

My face I'll grime with filth,
Blanket my loins, *elf* all my hair in knots. *Id.*

Thou *elvish* markt, abortive, rioting hog!
The slave of nature, and the son of hell! *Id.*

This is that very Mab,
That plats the manes of horses in the night,
And cakes the *elf-locks* in foul sluttish hairs,
Which, once untangled, much misfortune bodes.
*Id.*

No muse hath been so bold,
Or of the latter or the old,
Those *elvish* secrets to unfold,
Which lie from others reading.
*Drayton.*

Fairy *elves*,
Whose midnight revels by some forest side,
Or fountain, some belated peasant sees
Or dreams he sees. *Milton.*

From the like might proceed the fears of polling *elvelocks*, or complicated hairs of the head.
*Browne's Vulgar Errours.*

The king of *elfs* and little fairy queen
Gamboled on heaths, and danced on every green.
*Dryden.*

That we may angels seem, we paint them *elves*;
And are but satires to set up ourselves. *Id.*

However it was civil, an angel or *elf*;
For he ne'er could have filled it so well of himself
*Swift.*

Ye sylphs and sylphids to your chief give ear;
Fays, fairies, genii, *elves*, and demons hear. *Pope.*

Drawn by conceit from reason's plan,
How vain is that poor creature, man!
How pleased is every paltry *elf*
To prate about that thing himself. *Churchill.*

How from the yielding touch and rolling eyes
The piles immense of human science rise.—

With mind gigantic steps the puny *Elf*,
And weighs and measures all things but himself.
*Darwin.*

Here, seen of old, the elfin race
With sprightly vigils marked the place;
Their gay processions charmed the sight,
Gilding the lucid noon of night. *Id.*

Elf Arrows, in natural history, a name given to the flints anciently fashioned into arrow-heads, and still found fossile in Scotland, America, and several other parts of the world: they were believed to be shot by fairies, and that cattle were sometimes killed by them.

ELGIN or Elgyn, a royal borough of Scotland, and formerly a bishop's see, is situated on the river Lossie, about six miles north of the Spey. The name is probably derived from Helgy, general of the army of Sigurd, the Norwegian earl of Orkney, who, about 927, conquered Caithness, Sutherland, Ross, and Moray. It is said that he built a town in the south of Moray, which it is probable was Elgin. Many Norwegian princes were also named Helgy, and the inscription upon the town seal is, 'S. commune civitatis de Helgyn,' engraved in Saxon characters, in a style earlier than the middle of the sixteenth century. In the reign of William the Lion, Elgin had a royal fort. Its most ancient charter in the archives is from Alexander II. in 1234, granting a guild to the burgesses with extensive privileges. Elgin is a good town, and has many of the houses built over piazzas; but, excepting its great cattle fairs, has little trade. It is principally remarkable for its ecclesiastical antiquities. The cathedral, now in ruins, has been formerly a very magnificent pile. The west door is richly ornamented. The choir is very beautiful, and has a fine light gallery running round it. At the east end are two rows of narrow windows, in an excellent Gothic taste. The chapter house is an octagon; the roof supported by a fine single column with neat carvings of coats of arms round the capital. There is still a tower on each side of this cathedral; but that in the centre, with the spire and whole roof, are fallen in; and form awful fragments, mixed with the battered monuments of knights and prelates. The cathedral was founded by Andrew de Moray, in 1224, on a piece of land granted by Alexander II.; and his remains were deposited in the choir, under a tomb of blue marble, in 1244. The great tower was built principally by John Innes, bishop of this see, as appears by the Latin inscription cut on one of the great pillars. At the west end of the town are to be seen the ruins of an ancient castle, in which Edward Bruce surprised an English garrison early in the fourteenth century. Elgin is a royal borough, and unites with Banff, Cullen, Inverary, and Kintore, in returning a member to parliament. The burgesses resident in the town are alone eligible to the magistracy. Sixty-three miles and a half north-west from Aberdeen, and 144 north from Edinburgh. Population between 3000 and 4000. The parish of Elgin is about ten miles in length and six in breadth. Population of the town and parish, 4602.

Elgin Marbles. These admirable works of ancient art, recently purchased by the public of the earl of Elgin, are derived chiefly from the temple of Minerva, in the Acropolis at Athens, originally known as the Hecatompedon, or of an hundred feet, on account of its breadth; and Parthenon, or Temple of the Virgin, from the character of its patroness. This edifice was erected under the administration of Pericles, by Phidias, and artists and architects employed under him, about B.C. 500. It was wholly built of white marble, and the plan was that which is technically called octastyle peripteral; that is to say, it was an oblong colonnade, having eight columns in the porticos, front and back, and fifteen down each side, exclusive of those at the angles; within the columns, at about the distance of nine feet, was the wall of the cella, or interior of the temple; and this cella was a peristyle, that is, it had a row of columns forming an internal colonnade; this colonnade in the Parthenon seems to have supported a gallery.

The interior was divided into two parts: that towards the east, or front, was the place of worship, and occupied about two-thirds of the length—here stood the statue of the goddess; the division to the west was called the opisthodomos, and it was here that the public treasures were kept.

The pediments or triangular spaces over the portico, were adorned with groups of statues. Pausanias says, 'the pediment of the front, or entrance, represented the birth of Minerva; and that of the back the Contest of Minerva and Neptune for Attica.' Att. c. 24. The Acropolis is entered from the westward, and, of course, the west end of the temple is that which first presents itself to the observer; and the east end was, at the earliest modern period when we have any record of it, shut in and built round with Turkish houses: from these two circumstances it has happened that travellers mistook the west for the front, and the east for the back, and they, therefore, erroneously applied what Pausanias had said of the one to the other, and, having once fallen into this error, they went on, moulding, by their own ingenious fancies, the remains of the groups of the several pediments into some kind of consistency with his relation.

So obstinately long-lived was this error, that though the ingenious and accurate Stuart, in the second volume of his beautiful and valuable Survey of Athens, establishes, beyond all doubt, that the principal front and entrance were to the eastward (as indeed was the case in all ancient temples), yet, from not consulting the original Greek, he adopts, as to the subject of the sculptures of the pediments, the common error, and argues as if Pausanias had said the west instead of the entrance, which is his real expression. This point has been, of late, fully explained and decided by the work of the Chevalier Visconti on the Elgin marbles, London, 1816.

The height of the statues in the pediments varied in size, according to the increasing height of the cornice under which they were placed, from about seven feet to twelve; but as the pediment at each angle came, of course, to a point, erect figures of even the lowest stature could not be introduced; but the artist overcame this

difficulty with admirable skill, for the statues nearest the angles were recumbent, with their feet towards the angles; next came sitting figures, then figures in higher attitudes, and lastly, towards the centre, the chief figures of the composition upright and at full length. The next portion of the temple which we are to examine is the entablature, which surmounted the entire colonnade. The frieze of this entablature was composed of the well known Doric architectural ornaments called triglyphs, and of sculptured ornaments called metopes, placed alternately, the triglyph being over the centres of each column and of each intercolumniation, and the metopes occupying the intervals; each of these metopes consisted of a block of marble about three feet square, representing in bold *high-relief* the combat of a Lapitha with a Centaur. This subject was, on account of Theseus, who had overcome the Centaurs, one of national interest with the Athenians, and it seems to have been a very favorite subject in all sculptures of this period. It was depicted, as Pliny tells us, on the sandals of Minerva in the temple; it ornamented, as we still see, the frieze of the temple of Theseus, and it was again introduced in the frieze of the temple of Phigalia, which was built by Ictinus, one of the architects employed under Phidias on the Parthenon.

Another part of the Parthenon to which we must direct the attention of our readers is the frieze of the cella, or interior; this was an uninterrupted series of sculpture in blocks of marble about three feet high, that ran round the upper part of the wall, which, as we before stated, was about nine feet within the external row of columns; this frieze, with peculiar taste and judgment, represented, in very *low-relief*, the Panathenaic Procession, the highest festival of the Athenians, the solemnity in which the whole people conveyed, in solemn pomp, to this very temple, the sacred veil that was to be suspended over the statue of the goddess within.

These are the three classes of sculptures which adorned the exterior of the temple, and have alone come down to posterity; and it may not be here improper, though it is somewhat premature, to observe that the *perfect statue* of the pediment, the *high-relief* of the metope, and the *low-relief* of the frieze, include the only three species of which the art of sculpture is capable. In the pediments, which not only admitted, but required, on account of the situation as well as of the subjects, the boldest and noblest efforts of his art, Phidias represented divinities and heroes in full wrought statues of the colossal size, grouped with all the variety of attitude, expression, and sentiment. In the metopes, which, from their situation between the triglyphs, and their distance from the eye, ran the risk of being indistinct, he employed the highest relief of which there is any instance extant; in fact these groups are almost statues, and adhere to the blocks of marble by a very slight contact: but in the wall of the cell, which was surrounded by the ambulatory, this high-relief would have had two ill effects—it would have jetted out unpleasantly over the heads of the spectators, and prevented their having a perfect view of its composition, and as the only light by which it could be seen was reflected, broken, and unequal, (being admitted through the intercolumniations), the violent shadows of a high-relief would have perplexed and defeated the artist's design; for this situation, therefore, he employed relief so very low, that though it is the most exquisite and striking work of the ancient chisel, and though it expresses action, light, and shade in the highest perfection, it does not, in any part, project above an inch, and, in truth, exhibits all the force of relief with all the smoothness and delicacy of a drawing.

These details will at once prepare our readers to see how this great artist joined to the most fertile fancy, the truest taste, and the most perfect architectural science; and to understand the important acquisitions to our English school of sculpture, which the following list of the Elgin marbles presents.

We now, therefore, insert an abstract of the official catalogue, drawn up from the notes of the learned Visconti, of all the articles of the Elgin collection; and afterwards insert various testimonies to their value both as antiques and as works of art.

From the Parthenon there are ninety-two pieces, of which six statues or fragments of statues are stated to be from the eastern pediment, five from the western pediment, and six, the places of which (Report 71) are not ascertained. Of the metopes in high-relief there are fourteen. Of the frieze of the cell, in low-relief, there are, in all, fifty-two pieces, viz. twelve from the east end, fourteen from the north side, one from the west, fourteen from the east, and ten whose places are not ascertained.

Lord Elgin has also obtained a variety of other articles of considerable curiosity and value, which are stated in the same document, and are included in his lordship's offer to the public, viz. From the Temple of Victory there are four pieces of high-relief.—From the triple Temple of Erectheus, Minerva Polias, and Pandrosa, eighteen architectural specimens.—Seven architectural Doric specimens from the Propylea, Parthenon, &c.—Three pieces from the theatre of Bacchus.—Thirteen detached heads or fragments of heads.—Thirty-five detached pieces of various sculpture.—Eleven marble and three bronze urns; and some hundreds of vases, dug up in or near Athens. One of the bronze urns was found in what is called the tomb of Aspasia.—Eight altars.—Thirteen sepulchral pillars or cippi.—Forty-four casts in plaster of Paris of the friezes of the Parthenon, the temple of Theseus, and the Choraic monument of Lysicrates.

In a collection so extensive, there must be a great variety in the worth and beauty of the articles; though there is scarcely one that is not in a high degree curious and interesting: but it is to the sculptures of the Parthenon that the collection owes its chief reputation and most transcendant value. Before the splendor of their beauty every thing else fades away, and, compared with them, this crowd of minor antiquities appears almost worthless. But, at the head of all, in excellence, the best judges have placed two statues, one of which occupied the left corner of the eastern, and the other the same place

in the western pediment.' The situation in which these statues were placed in the original composition, would not have led us to imagine that they had been the peculiar objects of the artist's care, and yet they certainly excel, not only all that has been found in the same temple, but, in the best opinions, all the statues in the world. The humble situation, if we may use the expression, which they occupied in the pediment, is probably the cause of their present superiority; they were more sheltered from the injuries of time or accident, and, although much mutilated and weather-worn, they exhibit such a degree of excellence as leaves us at a loss to conceive any higher degree of merit, or to imagine how the rest of the composition could be kept on a scale of excellence answerable to these subordinate parts. But our readers will be glad to hear what our superior artists and connoisseurs say of these admirable sculptures.

We follow the House of Commons' Report of their testimony:—Mr. Nollekens rates these marbles in the same class with the finest sculptures of Italy, and beyond any thing that this country before possessed; and he adds, that the Theseus is, in his opinion, equal to the Apollo Belvedere.—*Report*, p. 30.

Mr. Flaxman considers the Elgin marbles as the finest works of art which he has seen; and he especially places the Theseus in the first order of merit: but, when the Theseus is compared with the Apollo Belvedere, Mr. Flaxman would prefer the latter, because the Theseus is a mere representation of nature, fine nature indeed, but mere nature; and the Apollo is a higher effort of the art, namely, an attempt at the perfection of ideal beauty.—*Report*, p 30.

Mr. Westmacott considers the whole collection as of the first class of art, but the Theseus and Ilissus he thinks unequalled—they are infinitely superior to the Apollo Belvedere, because they unite the greatest dignity of style with the greatest truth of nature, and that the Apollo is merely an ideal figure. He cannot readily determine which he prefers, the Theseus or the Ilissus: the back of the Theseus is the finest thing in the world, and the front of the Ilissus is not surpassed by any known work of art.—*Report*, p. 33.

On this very just observation of Mr. Westmacott's it is worth remarking, that the parts of each statue which he thus distinguishes, are those in which the surface happens to be most perfect, and in which of course the hand of the original master is more distinctly visible.

Mr. Chauntry, though he does not state distinctly that he prefers these statues to the Apollo, seems to consider them as higher specimens of the art. The characters of the works, he truly observes, are not comparable; the Elgin statues are groups in the simplest and grandest style of nature. The Apollo is a single figure, wrought out with a degree of finish that would have been mischievous in the former. At the same time Mr. Chauntry remarks, that though these statues have all this grand simplicity of nature, and are calculated to produce the greatest effect in the distant position for which they were intended, they are yet executed with a degree of finish which is quite surprising, and which yet detracted nothing from the magnificence of their local effect.—*Report*, p. 37.

Mr. Rossi considers the Theseus and Ilissus as superior to the Apollo and Laöcoon, and he adds the important verbal testimony of Canova, with whom he had personally visited the marbles, 'that they were as fine things as he had ever seen.'—*Report*, p. 37.

Mr. Wilkins, a gentleman of taste and learning, and of well-merited eminence in his own profession as an architect, ranks the Elgin marbles 'in the very highest order of art.'—*Report*, p. 43.

Not less decisive was the opinion of Mr. West, the late president of the Royal Academy, and Sir Thomas Lawrence, without whose opinion the Committee appear (very properly) to have thought their Report would not be satisfactory to the public.

The president considered the Theseus and Ilissus, the Torso of Neptune, and the Horse's Head, as in the first class of dignified art employed on the finest specimens of nature. The Apollo and Torso of the Belvedere, and the Laöcoon, as specimens of systematic art—the production of ideal form by mechanical principles.—Report, p. 59. And he states, both in his evidence, and in a letter subjoined to the Pursuits, with a modesty and force which do equal honor to himself and these marbles, that he has worked from them, as a student, for his own improvement.—Pursuits, p. 52. That he has patiently drawn the most distinguished of them, the same size of the marbles; that he has introduced their spirit and forms, as far as he was capable of catching them, into his own compositions; and he adds:—

'Had I been blessed with seeing and studying these emanations of genius at an earlier period of life, the sentiment of their pre-eminence would have animated all my exertions; and more character, and expression, and life, would have pervaded all my humble attempts in historical painting.'—*Pursuits*, pp. 54, 55.

We cannot refuse ourselves the pleasure of extracting another passage of his letter, in which this amiable old man poured forth his gratitude for the benefit which lord Elgin has conferred on the arts of his country.

'In whatever estimation the arts of the present day shall be held by those of future ages, your lordship must be remembered by the present, and be recorded by those to come, as a benefactor, who has conferred obligations, not only on a profession, but upon a nation; and as having rescued from the devastation of ignorance, and the unholy rapine of barbarism, those unrivalled works of genius, to be preserved in the bosom of your country, which a few centuries more might have consigned to oblivion.'—*Pursuits*, p. 52.

The opinion of Sir Thomas Lawrence is marked by that fine genius and taste which those who know him find in his conversation, and which all admire in the efforts of his pencil.

He considers the Elgin marbles as in the very highest class of art; and after having made himself minutely acquainted with the chefs-

d'œuvre in the gallery of the Louvre, he pronounces the Elgin statues to be of a higher class than the Apollo; because, as he judiciously marks the distinction, there is in them a union of fine composition and grandeur of form, with a more true and perfect expression of nature, than there is in the Apollo, or in any other of the most celebrated statues;—there is in them all that beautiful and harmonious variety which is produced in the human form by the alternate repose and action of the muscles; and it is impossible, he adds, after looking at the Elgin statues, to look at the casts of other celebrated works, without being struck by the inferiority of the latter in this respect.

The earl of Aberdeen, in his evidence, which is of considerable length, and which does the greatest credit to his candor, learning, and good taste, rates them in the highest class of art.

And finally, Canova, the most celebrated sculptor of modern times, in addition to his verbal expressions of admiration, left, in a letter to lord Elgin, his recorded judgment of them.

London, Nov. 10, 1815.

'Permit me to express the sense of the great gratification which I have received from having seen in London the valuable antique marbles, which you have brought hither from Greece. I think that I can never see them often enough: and, although my stay in this great capital must be extremely short, I dedicate every moment that I can spare to the contemplation of these celebrated remains of ancient art. I admire in them the truth of nature united to the choice of the finest forms. Every thing here breathes life, with a veracity, with an exquisite knowledge of art, but, without the least ostentation or parade of it, which is concealed by consummate and masterly skill. The naked is perfect flesh, and most beautiful in its kind. I think myself happy in having been able to see with my own eyes these distinguished works; and I should feel perfectly satisfied if I had come to London only to view them. Upon which account the admirers of art, and the artists, will owe to your lordship a lasting debt of gratitude, for having brought amongst us these noble and magnificent pieces of sculpture; and for my own part I beg leave to return you my own most cordial acknowledgments.'

'Nothing, perhaps, after all,' however, says the Quarterly Reviewer, 'will surprise the common observer more than the extraordinary praises which are lavished upon what appear to them to be little better than mutilated and shapeless fragments—to their eyes in no degree ornamental, and to their judgments of no kind of utility. It must be confessed that the details of those sculptures have been greatly and lamentably degraded; but there remains enough amply to gratify the eye of taste, and to guide and form the powers of the student. It should be recollected, in considering this point of the subject, that not one of the great statues of the ancient world was found in a perfect state. The Venus de Medicis is in, we know not how many, pieces, and both the arms, at least, are modern—of the Apollo, the most perfect of ancient sculptures, one hand and one arm are modern, and both the legs were broken. Of the beautiful Ceres, one of the most exquisite remains of antiquity, the head, though undoubtedly antique, does not belong to the body. The Torso, every one knows, is a mere trunk, without limbs or head. The Barberini Faun, which we have heard called the most perfect statue in the world, wants the legs and hands. The Laöcoon has been restored; and, in short, all those admirable specimens of the arts, when first found, would have excited to the common observer the same disappointment, though in various degrees, which the Elgin marbles have excited in some ordinary visitors; but it is with them as with the cartoons and frescos of Raphael, if disappointment clouds the first visit, it vanishes at the second; and, by a more constant examination of those divine models, a purity of taste and accuracy of judgment grows up in the mind of the student, till at last, not his fancy, but his judgment, supplies the deficiencies, and repairs the damages of accident and time.

'Who is there, however unskilled in the arts, who can, for any time, look on the representation of the Panathenaic procession without the highest intellectual delight, that festival of the metropolis of the civilised world, connected with all the delicious remembrances of Athenian history, designed by the hand of Phidias, from the living procession in which Pericles, and Socrates, and Aspasia walked, and exhibiting on the marble which we may now call eternal, the noblest moral recollections with the most exquisite forms of natural beauty;—who is there, we say, who can look at this admirable work without feeling that expansion of the heart, that exaltation of the mind, which it is the first and proudest office of the fine arts to create.'

These marbles were finally secured to the public for the sum of £35,600, we believe, and are deposited in the British Museum. Many foreigners are said to have already come into this country, solely for the purpose of seeing them; and casts from the whole collection have been sent to Bavaria, to Wirtemberg, to Russia: others have been ordered for Florence. 'The school of sculpture,' adds the critic we have before quoted, 'will soon be in England.'

ELI, Heb. עלי, i. e. offering, high priest of Israel, and the last of the judges except Samuel, succeeded Samson, about A. M. 2848; and A.A.C. 1156. His too gentle government, particularly towards his sons, the practisers of the greatest wickedness, and the consequent misfortunes of his family and the commonwealth, are recorded in 1 Sam. iv. xiv. and xxii. He died in the fortieth year of his government, and ninety-eighth of his age, A. M. 2888, and A. A. C. 1116.

ELIAS, or ELIJAH, from אל, God, and יה, the Lord, an eminent prophet of Israel, who escaped the common lot of mankind, by not suffering death; being translated, about A. M. 3108, and A. A. C. 896. His miracles, persecutions, and ascension to heaven, are recorded in 1 Kings xvii—xxi.; 2 Kings i. and ii.

ELICHMAN (John), a native of Silesia in the seventeenth century, who practised physic

at Leyden, and was remarkable for his knowledge of sixteen languages. He supported an opinion, that the German and Persian languages were derived from the same origin. His Latin translation of the Tablet of Cebes, with the Arabic version and the Greek, was printed at Leyden in 1640, under the care of Salmasius, who prefixed thereto a very ample preface.

ELICHPOOR, a town and district of the province of Berar, Hindostan. It belongs to the nizam, and lies between the twentieth and twenty-second degrees of northern latitude: it is separated from the territories of the Berar rajah by the river Burda. The capital was formerly the chief town of all Berar, and is said to have been founded in very ancient times, by rajah Elloo; it stands on a branch of the Burda, and is a fortified place. In 1772 it was besieged by the Mahrattas, who retired upon payment of the tribute: it was then governed by a deputy of the nizam, who bore the title of nabob, and in the year 1777 endeavoured to establish his independence; but he was soon surrounded by the troops of the former, and was killed in battle. His family being made prisoners, all his property was confiscated. It is still governed by a deputy, who has charge of the district.

ELIC'IT, *v. a.* & *adj.* }
ELIC'ITATE, *v. a.* }
ELICITA'TION, *n. s.* } Lat. *elicio, elicitum*, to draw out. To strike or bring out by labor or art. The verbs are synonymous: as an adjective elicit means brought into action, or actual existence.

It is the virtue of humility and obedience, and not the formal *elicit* act of meekness; meekness being ordinarily annexed to these virtues. *Hammond.*

The schools dispute whether, in morals, the external action superadds any thing of good or evil to the internal *elicit* act of the will. *South.*

That *elicitation* which the schools intend, is a deducing of the power of the will into act: that drawing which they mention, is merely from the appetibility of the object. *Bramhall.*

Although the same truths may be *elicited*, and explicated by the contemplation of animals, yet they are more clearly evidenced in the contemplation of man. *Hale's Origin of Mankind.*

He *elicits* those acts out of the meer lapsed state of human nature. *Cheyne.*

ELIDE', *v. a.* }
ELI'SION, *n. s.* } Fr. *elider*; Lat. *elido, elisus*; to strike off; to break off or from: hence to break in pieces.

We are to cut off that whereunto they, from whom these objections proceed, fly for defence, when the force and strength of the argument is *elided*. *Hooker.*

The cause given of sound, that it would be an *elision* of the air, whereby, if they mean any thing, they mean a cutting or dividing, or else an attenuating of the air, is but a term of ignorance. *Bacon's Natural History.*

You will observe the abbreviation and *elisions*, by which consonants of most obdurate sounds are joined together, without any softening vowel to intervene. *Swift.*

EL'IGIBLE, *adj.* }
ELIGIBIL'ITY, *n. s.* } Lat. *eligibilis, eligo*, to choose. Fit to be chosen; preferable. Eligibility is worthiness, or legal fitness to be chosen.

Certainty, in a deep distress, is more *eligible* than suspense. *Clarissa.*

The business of the will is not to judge concerning the nature of things, but to choose them in consequence of the report made by the understanding, as to their *eligibility* or goodness. *Fiddes's Sermons.*

A British ministry ought to be satisfied, if, allowing to every particular man that his private scheme is wisest, they can persuade him, that next to his own plan, that of the government is the most *eligible*. *Addison's Freeholder.*

Did they really think, that going on with the war was more *eligible* for their country than the least abatement of those conditions? *Swift.*

Through tomes of fable and of dream,
I sought an *eligible* theme;
But none I found, or found them shared
Already by some happier bard. *Cowper.*

ELIHU, from Heb. אלי and הוא, i. e. he is my God, the son of Barachel the Buzite, a descendant of Buz, the son of Nahor, Abraham's brother, and the youngest of Job's friends who visited him in his affliction. His remarkable speech to Job, and his senior friends, is recorded in the thirty-second and five following chapters. From some passages in that speech, particularly in chap. xxxiii. ver. 4 and 6, as well as from the propriety of the sentiments expressed in it, and the signification of the name Elihu, and more especially from the Almighty himself being introduced as the next speaker, some commentators have supposed, that our Saviour is meant by this personage. Others have supposed that Elihu was the author of the book of Job, from the fifteenth and sixteenth verses of chap. xxxii. where he seems to speak of himself as the writer of the narrative, and of the effect of his words upon Job's three senior friends. But these two verses are indeed evidently a parenthesis, and cannot, by any construction of language, be reckoned a part of the speech, which precedes and follows them.

ELIM'INATE, *v. a.* }
ELIMINA'TION, *n. s.* } Fr. *eliminer*; Lat. *elimino*, from *e* and *limen*, the threshold of a door; to put beyond the door; to banish: hence to set free; liberate.

*Eliminate* my Spirit, give it range
Through provinces of thought yet unexplored,
Teach me by this stupendous scaffolding,
Creation's golden steps, to climb to Thee.
*Young.*

ELIOTT, or ELLIOT (George Augustus), Lord Heathfield, was the youngest son of Sir Gilbert Eliott, Bart. of Stobbs, in Roxburghshire, where lord Heathfield was born in 1718. He received the first rudiments of his education under a private tutor; and was early sent to the university of Leyden. Being designed for a military life, he was sent from thence to the celebrated Ecole Royale du Genie Militaire, conducted by the great Vauban, at La Fere, in Picardy, where he laid the foundation of what he so conspicuously exhibited at the defence of Gibraltar. He returned to Scotland in 1735, in the seventeenth year of his age, and was introduced by his father to lieutenant-colonel Peers, of the twenty-third regiment of foot, then lying at Edinburgh. He was accordingly entered as a volunteer in that regiment, where he continued for a year or more: he then went into the engineer corps at

Woolwich, where he continued till 1740, when his uncle Colonel Eliott appointed him his adjutant of the second troop of horse grenadiers. With these troops he went upon service to Germany, and was with them in a variety of actions. In this regiment he bought the rank of captain and major, and afterwards purchased the lieutenant-colonelcy from Colonel Brewerton, who succeeded to his uncle. Soon after this he was appointed aid-de-camp to George II., and was distinguished for his military skill and discipline. In March 1759 he quitted the second troop of horse grenadier guards, being selected to raise, form, and discipline, the first regiment of light horse, called after him Eliott's regiment. As soon as they were raised and formed, he was appointed to the command of the cavalry in the expedition on the coasts of France, with the rank of brigadier general. After this he passed into Germany, where he was employed on the staff, and greatly distinguished himself in a variety of movements; particularly at the battle of Minden, where he headed the second line of horse under the marquis of Granby; and where his regiment displayed a strictness of discipline, an activity and enterprise, which gained them signal honor. From Germany he was recalled in 1762, for the purpose of being employed as second in command in the memorable expedition against the Havannah. On the peace in 1763 his regiment was reviewed by the king, when they presented to his majesty the standards which they had taken from the enemy. Gratified with their fine discipline and high character, the king appointed it a royal regiment, naming it the 15th, or King's Royal Regiment of Light Dragoons. In 1774 he was appointed to succeed general A'Court as commander in chief of the forces in Ireland; but he soon solicited to be recalled. He accordingly was so, and appointed to the command of Gibraltar in a fortunate hour for the safety of that important fortress. His gallant defence of this besieged rock is too well known to every Englishman, and too intimately connected with English history, to need a separate description here. See England, History of. On his return to England, the gratitude of the British senate was as forward as the public voice in giving him that distinguished mark his merit deserved. Both houses of parliament voted a unanimous address of thanks to the general. The king conferred on him the honor of Knight of the Bath, with a pension during his own and a second life of his own appointment; and on June 14th, 1787, his majesty advanced him to the peerage by the title of Lord Heathfield, Baron Gibraltar, permitting him to take, in addition to his family arms, the arms of the fortress he had so bravely defended, to perpetuate to futurity his noble conduct. He died at his chateau at Aix-la-Chapelle, on the 6th of July, 1790, in the seventy-third year of his age, of a second stroke of the palsy; after having for some weeks preceding enjoyed a tolerably good share of health, and an unusual flow of spirits. His remains were brought to England, and buried at Heathfield in Sussex, where a monument is erected to his memory.

ELIPHAZ; from אל, and פיז, i. e. the strength of God; the eldest of Job's three uncharitable friends. From his being styled the Temanite, it is evident that he was a descendant of Esau, by Teman, the son of Eliphaz, and grandson of Esau, the first duke of Edom.

ELIQUATION, in chemistry, an operation by which a more fusible substance is separated from one that is less so, by means of a heat sufficiently intense to melt the former, but not the latter. Thus an alloy of copper and lead may be separated by a heat capable of melting the latter, but not the former.

ELIS, or Elea, in ancient geography, a fertile district of Peloponnesus, famous for raising flax, which equalled that of Judea in fineness, though not so yellow, and grew no where else in Greece.

Elis, the capital of the above district, situated on the Peneus, which ran through it. It was the country of Phædo the friend of Plato, and of Pyrrho the founder of the Pyrrhonists. This city owed its origin to a union of small towns after the Persian war. It was not encompassed immediately with a wall; for it had the care of the temple at Olympia, and its territory was solemnly consecrated to Jupiter. To invade or not protect it was deemed impiety; and armies, if marching through it, delivered up their weapons, which, on their quitting it, were restored. Amidst warring states this city enjoyed repose, was resorted to by strangers, and flourished. It was a school for Olympia, which was distant thirty-seven miles. The athletic exercises were performed there, before the more solemn trial, in a gymnasium, by which the Peneus ran. There also was the town-hall, in which extemporary harangues were spoken and compositions recited. It was hung round with bucklers for ornaments. A way led from it to the baths through the Secret of Silence; and another to the market-place, which was planned with streets between porticoes of the Doric order adorned with altars and images. Among the temples one had a circular peristyle or colonnade; but the image had been removed and the roof was fallen in the time of Pausanias. The theatre was ancient, as was also a temple of Bacchus, one of the deities principally adored at Elis. Minerva had a temple in the citadel, with an image of ivory and gold made by Phidias. At the gate leading to Olympia was the monument of a person, who was buried, as an oracle had commanded, neither within nor without the city. The structures of Elis, Dr. Chandler observes, seem to have been raised with materials far less elegant and durable than the produce of the Ionian and Attic quarries. The ruins are of brick, and not considerable, consisting of pieces of ordinary walls, and an octagon building with niches, which, it is supposed, was the temple with a circular peristyle. These stand detached from each other, ranging in a vale southward from the wide bed of the river Peneus; which, by the margin, has several large stones, perhaps reliques of the gymnasium. The citadel was on a hill, which has on the top some remnants of a wall.

ELISHA, or Elisæus; from Heb. אל and ישע, i. e. the salvation of God; the son of Sha-

phat, an eminent prophet of Israel, the disciple and successor of Elijah. His call, with his various miracles and prophecies, are recorded in 1 Kings, xix. xxi.; 2 Kings, ii.—viii. and xiii. He died much lamented by Joash king of Israel, A. M. 3165, and A. A. C. 839.

ELISHAH, the son of Javan, and grandson of Japhet, is supposed by chronologists to have been the progenitor of the inhabitants of Eolia, in Lesser Asia, and of Elis and Alisium in Peloponnesus.

ELI'SION. See ELIDE.

ELIX'ATE, *v. a.* } Lat. *elixare*, to boil: but ELIXA'TION, *n. s.* } all etymologists derive ELIX'IR. } *elixir*, so written in Fr. Ital. Span. Port. and Lat. from the Arabic; Mr. Thomson says, from the Arab. *al uxseer*. Elixation is the act or state of boiling. Elixir is a supposed quintessence, 'or the philosopher's stone, or one of the names thereof. Some take it for the chemical powder of production,' says Minsheu. 'The word signifieth force or strength,' he adds. It is used for any cordial.

> No chymist yet the *elixir* got,
> But glorifies his pregnant pot,
> If by the way to him befal
> Some odoriferous thing, or medicinal.
> *Donne.*

> What wonder then, if fields and regions here
> Breathe forth *elixir* pure! *Milton's Paradise Lost.*

> ——— Bring Quintessence of *elixer* pale,
> Out of sublimed spirits minerall.
> *Bp. Hall. Satires.*

Even to ourselves, and more perfect animals, water performs no substantial nutrition; serving for refrigeration, dilution of solid aliments, and its *elixation* in the stomach. *Browne.*

In the soul, when the supreme faculties move regularly, the inferior passions and affections following, there arises a serenity infinitely beyond the highest quintessence and *elixir* of worldly delight. *South.*

> For when no healing art prevailed,
> When cordials and *elixirs* failed,
> On your pale cheek he dropped the shower,
> Revived you like a dying flower. *Waller.*

When we see men grow old, and die at a certain time one after another, from century to century, we laugh at the *elixir* that promises to prolong life to a thousand years. *Dr. Johnson.*

ELIXIR, in medicine, is defined by others, a compound tincture extracted from many efficacious ingredients. The difference between a tincture and an elixir seems to be this, that a tincture is drawn from one ingredient, sometimes with an addition of another to open it and to dispose it to yield to the menstruum; whereas an elixir is a tincture extracted from several ingredients at the same time.

ELIZABETH, queen of England, daughter of Henry VIII. and Anne Boleyn, was born at Greenwich, September 7th, 1533. She was early instructed in the learned languages, first by Grindal, and afterwards by the celebrated Roger Ascham. She acquired likewise considerable knowledge of the Italian, Spanish, and French, languages. Dr. Grindal was also her preceptor in divinity, which she is said to have studied with uncommon application and industry. That Elizabeth became a Protestant, and her sister Mary a Papist, was the effect of that cause which determines the religion of the most of mankind; namely, the opinions of those by whom they are educated: and this difference of opinion, in their tutors, is not at all surprising, when we recollect, that their father was of both religions, and of neither. But the studies of Elizabeth were not confined merely to languages and theology; she was acquainted with the political history of the ancients; and was also well skilled in music. After the short reign of her brother Edward, our heroine being then about twenty years of age, and her bigoted sister acceding to the crown, Elizabeth experienced a considerable degree of persecution, so as to be even apprehensive of a violent death. She was imprisoned; and we are told inhumanly treated. At last, by the intercession of king Philip of Spain, she was set at liberty; which she continued to enjoy till, on the death of her sister, she, on the 17th of November, 1558, ascended the throne of England. Her political history as a queen, is universally known and admired. See ENGLAND. But her attention to government did not suspend her pursuit of learning. Ascham, in his Schoolmaster, tells us, that, about 1563, five years after her accession, she being then at Windsor, 'besides her perfect readiness in Latin, Italian, French, and Spanish, she read more Greek in one day than some prebendaries of that church did read Latin in a whole week.' She employed Sir John Fortescue to read to her Thucydides, Xenophon, Polybius, Euripides, Æschines, and Sophocles.—Ballard, p. 219. That the Latin language was familiar to her, is evident from her speech to the university of Oxford, when she was near sixty; as well as from her spirited answer to the Polish ambassador in 1598. 'But,' says Walpole, 'a greater instance of her genius, and that too in Latin, was her extempore reply to an insolent prohibition delivered to her from Philip II. by his ambassador, in this tetrastic.

> Te veto ne pergas bello defendere Belgas:
> Quæ Dracus eripuit, nunc restituantur oportet:
> Quas pater evertit, jubeo te condere cellas:
> Religio papæ fac restituatur ad unguem.

'She instantly answered him, with as much spirit as she used to return his invasions,'

> Ad Græcas, bone rex, fient mandata kalendas.

Being pressed by a Romish priest, during her persecution, to declare her opinion concerning the real presence of Christ's body in the wafer, she answered, it is said,

> Christ was the Word that spake it;
> He took the bread and brake it;
> And what that Word did make it,
> That I believe and take it.

Sir Walter Raleigh having wrote on a window,

> Fain would I climb, yet fear I to fall;

She immediately wrote under it.

> If thy heart fail thee climb not at all.
> *Worthies of Devonshire,* 261.

Elizabeth was doubtless a woman of singular capacity and extraordinary acquirements; and, if we could forget the fate of her cousin, queen Mary, and of her own favorite, Essex, together with the burning of the anabaptists; in short,

could we forbear to contemplate her character through the medium of religion and morality, we might pronounce her the most illustrious of illustrious women. See England, Mary, and Scotland. She died at Richmond the 24th March, 1602, aged seventy, having reigned forty-four years, and was interred in the chapel of Henry VII. in Westminster Abbey. Her successor, James, erected a magnificent monument to her memory. She wrote, 1. The Mirrour or Glass of the Sinful Soul. This was translated out of French verse into English prose, when she was eleven years old. It was dedicated to queen Catherine Parr. Probably it was never printed; but the dedication and preface are preserved in the Sylloge epistolarum, in Hearne's edition of Livii Foro-Juliensis, p. 161. 2. Prayers and Meditations, &c.; dedicated to her father, dated at Hatfield, 1545, MS. in the royal library. 3. A Dialogue out of Xenophon, in Greek, between Hiero a king, yet some time a private person, and Simonides, a poet, as touching the life of the prince and private man; first printed from a MS. in her own hand writing, in the Gentleman's Magazine, for 1743. 4. Two Orations of Isocrates, translated into Latin. 5. Latin Oration at Cambridge, preserved in the king's library, in Hollingshed's Chronicles, p. 1206; and in Fuller's History of Cambridge, p. 138. 6. Latin Oration at Oxford; in Wood's History and Antiquities of Oxford, lib. i. p. 289; also in Dr. Jebb's Appendix to his Life of Mary, Queen of Scots. 7. A Comment on Plato. 8. Boethius de Consolatione Philosophiæ, translated into English, 1593. 9. Sallustius de Bello Jugurthino, translated into English, 1590. 10. A Play of Euripides, translated into Latin, Cat. of Royal Auth. 11. A Prayer, for the use of her fleet in the great expedition in 1596. 12. Part of Horace's Art of Poetry, translated into English, anno 1598. 13. Plutarch de curiositate, translated into English. 14. Letters on various occasions to different persons; several Speeches to her Parliament; and a number of other pieces.

Dr. Lingard, the Catholic historian, has given us a character of this princess which displays the usual research and elaborate care of his work. It is perhaps, as a whole, a fair specimen of his History of England. We subjoin the principal part of it.

'In the judgment of her contemporaries,' he says, 'and that judgment has been ratified by the consent of posterity, Elizabeth was numbered among the greatest and most fortunate of our princes. The tranquillity which, during a reign of nearly half a century, she maintained within her dominions, while the neighbouring nations were convulsed with intestine dissensions, was taken as a proof of the wisdom or the vigor of her government: and her successful resistance against the Spanish monarch, the many injuries which she inflicted on that lord of so many kingdoms, and the spirit displayed by her fleets and armies, in expeditions to France and the Netherlands, to Spain, to the West and even to the East Indies, served to give to the world an exalted notion of her military and naval power. When she came to the throne, England ranked only among the secondary kingdoms; before her death it had risen to a level with the first nations in Europe.

'Of this rise two causes may be assigned. The one, though more remote, was that spirit of commercial enterprise, which had revived in the reign of Mary, and had been carefully fostered, in that of Elizabeth, by the patronage of the sovereign, and the co-operation of the great. Its benefits were not confined to the trading and sea-faring classes, the two interests more immediately concerned. It gave a new tone to the public mind: it diffused a new energy through all ranks of men. Their views became expanded: their powers were called into action: and the example of successful adventure furnished a powerful stimulus to the talent and industry of the nation. Men in every profession looked forward to wealth and independence: all were eager to start in the race of improvement.

'The other cause may be discovered in the system of foreign policy, adopted by the ministers; a policy, indeed, which it may be difficult to reconcile with honesty and good faith, but which, in the result, proved eminently successful. The reader has seen them perpetually on the watch to sow the seeds of dissension, to foment the spirit of resistance, and to aid the efforts of rebellion, in the neighbouring nations. In Scotland the authority of the crown was almost annihilated; France was reduced to an unexampled state of anarchy, poverty, and distress: and Spain beheld with dismay her wealth continually absorbed, and her armies annually perishing, among the dikes and sand-banks of the Low Countries. The depression of these powers, if not a positive, was a relative benefit. As other princes descended, the English queen appeared to rise on the scale of reputation and power.

'In what proportion the merit or demerit of these and of other measures should be shared between Elizabeth and her counsellors, it is impossible to determine. On many subjects she could see only with their eyes, and hear with their ears; yet it is evident that her judgment or her conscience frequently disapproved of their advice. Sometimes, after a long struggle, they submitted to her wisdom or obstinacy; sometimes she was terrified or seduced into the surrender of her own opinion: generally a compromise was effected by mutual concessions. This appears to have happened on most debates of importance, and particularly with respect to the treatment of the unfortunate queen of Scots. Elizabeth may perhaps have dissembled: she may have been actuated by jealousy or hatred: but, if we condemn, we should also remember the arts and frauds of the men by whom she was surrounded, the false information which they supplied, the imaginary dangers which they created, and the despatches which they dictated in England to be forwarded to the queen through the ambassadors in foreign courts, as the result of their own judgment and observation.

'It may be, that the habitual irresolution of Elizabeth was partially owing to her discovery of such practices: but there is reason to believe that it was a weakness inherent in the constitu-

tion of her mind. To deliberate appears to have been her delight: to resolve was her torment. She would receive advice from any; from foreigners as well as natives, from the ladies of her bed-chamber no less than the lords of her council: but her distrust begot hesitation; and she always suspected that some interested motive lurked under the pretence of zeal for her service. Hence she often suffered months, sometimes years, to roll away before she came to a conclusion: and then it required the same industry and address to keep her steady to her purpose, as it had already cost to bring her to it. The ministers, in their confidential correspondence, perpetually lamented this infirmity in the queen; in public they employed all their ingenuity to screen it from notice, and to give the semblance of wisdom to that which, in their own judgment, they characterised as folly.'

He then notices her alleged parsimony, and ascribes it, principally, to the lavish expenditure incurred by her foreign policy.

'An intelligent foreigner,' he continues, 'had described Elizabeth, while she was yet a subject, as haughty and overbearing: on the throne she was careful to display that notion of her own importance, that contempt of all beneath her, and that courage in the time of danger, which were characteristic of the Tudors. She seemed to have forgotten that she ever had a mother: but was proud to remind both herself and others that she was the daughter of a powerful monarch, of Henry VIII. On occasions of ceremony she appeared in all her splendor, accompanied by the great officers of state, and with a numerous retinue of lords and ladies dressed in their most gorgeous apparel. In reading the accounts of her court, we may sometimes fancy ourselves transported into the palace of an eastern princess. When Hentzner saw her she was proceeding on a Sunday from her own apartment to the chapel. First appeared a number of gentlemen, barons, earls, and knights of the garter; then came the chancellor with the seals, between two lords carrying the sceptre and the sword. Elizabeth followed: and wherever she cast her eyes, the spectators instantly fell on their knees. She was then in her sixty-fifth year. She wore false hair of a red color, surmounted with a crown of gold. The wrinkles of age were imprinted on her face; her eyes were small, her teeth black, her nose prominent. The collar of the garter hung from her neck; and her bosom was uncovered, as became an unmarried queen. Behind her followed a long train of young ladies dressed in white; and on each side stood a line of gentlemen pensioners, with their gilt battle-axes, in splendid uniforms.'

'The traveller next proceeded to the dining room. Two gentlemen entered to lay the cloth, two to bring the queen's plate, salt, and bread. All, before they approached the table, and when they retired from it, made three genuflexions. Then came a single and a married lady, performing the same ceremonies. The first rubbed the plate with bread and salt: the second gave a morsel of meat to each of the yeomen of the guard, who brought in the different courses; and at the same time the hall echoed to the sound of twelve trumpets, and two kettle-drums. But the queen dined that day in private; and, after a short pause, her maids of honor entered in procession, and, with much reverence and solemnity, took the dishes from the table, and carried them into an inner apartment. Yet while she maintained this state in public and in the palace, while she taught the proudest of the nobility to feel the distance between them and their sovereign, she condescended to court the good will of the common people. In the country they had access to her at all times; neither their rudeness nor importunity appeared to offend her: she received their petitions with an air of pleasure, thanked them for their expressions of attachment, and sought the opportunity of entering into private conversation with individuals. Her progresses were undoubtedly undertaken for pleasure: but she made them subservient to policy, and increased her popularity by her affability and condescension to the private inhabitants of the counties in which she made her temporary abode.'

'From the elevation of the throne, we may now follow Elizabeth into the privacy of domestic life. Her natural abilities were great: she had studied under experienced masters; and her stock of literature was much more ample than that of most females of the age. Like her sister Mary, she possessed a knowledge of five languages: but Mary did not venture to converse in Italian, neither could she construe the Greek Testament, like Elizabeth. The queen is said to have excelled on the virginals, and to have understood the most difficult music. But dancing was her principal delight: and in that exercise she displayed a grace and spirit which was universally admired. She retained her partiality for it to the last: few days passed in which the young nobility of the court were not called to dance before their sovereign; and the queen herself condescended to perform her part in a galliard with the duke of Nevers, at the age of sixty-nine.'

'It is seldom that females have the boldness to become the heralds of their own charms: but Elizabeth by proclamation announced to her people, that none of the portraits, which had hitherto been taken of her person, did justice to the original: that at the request of her council she had resolved to procure an exact likeness from the pencil of some able artist: that it should soon be published for the gratification of her loving subjects: and that on this account she strictly forbad all persons whatsoever, to [illegible] or engrave any new portraits of her features [illegible] license, or to show or publish any of the old portraits, till they had been reformed according to the copy to be set forth by authority. The courtiers soon discovered how greedy their sovereign was of flattery. If they sought to please, they were careful to admire: and adulation the most fulsome and extravagant, was accepted by the queen with gratitude, and rewarded with bounty. Neither was her appetite for praise cloyed, it seemed rather to become more craving, by enjoyment. After she had passed her grand climacteric she exacted the same homage to her faded charms as had been paid to

her youth; and all who addressed her were still careful to express their admiration of her beauty in the language of oriental hyperbole.

'In her temper Elizabeth seemed to have inherited the irritability of her father. The least inattention, the slightest provocation, would throw her into a passion. At all times her discourse was sprinkled with oaths: in the sallies of her anger it abounded with imprecations and abuse. Nor did she content herself with words: not only the ladies about her person, but her courtiers and the highest officers in the state, felt the weight of her hands. She collared Hatton, she gave a blow on the ear to the earl-marshal, and she spat on Sir Matthew ———, with the foppery of whose dress she was offended.

'Elizabeth firmly believed, and zealously upheld, the principles of government established by her father, the exercise of absolute authority by the sovereign, and the duty of passive obedience in the subject. The doctrine, with which the lord keeper Bacon opened her first parliament, was indefatigably inculcated by all his successors during her reign, that, if the queen consulted the two houses, it was through choice, not through necessity, to the end that her laws might be more satisfactory to her people, not that they might derive any force from their assent. She possessed by her prerogative whatever was requisite for the government of the realm. She could, at her pleasure, suspend the operation of existing statutes, or issue proclamations which should have the force of law. In her opinion the chief use of parliaments was to vote money, to regulate the minutiæ of trade, and to legislate for individual and local interests. To the lower house she granted, indeed, freedom of debate; but it was to be a decent freedom, the liberty of 'saying aye or no;' and those who transgressed that decency were liable, we have repeatedly seen, to feel the weight of the royal displeasure.

'The historians, who celebrate the golden days of Elizabeth, have described with a glowing pencil, the happiness of the people under her sway. To them might be opposed the dismal picture of national misery, drawn by the catholic writers of the same period. But both have taken too contracted a view of the subject. Religious dissension had divided the nation into opposite parties, of almost equal numbers, the oppressors and the oppressed. This estimate of "England's Maiden Queen," though from the pen of a Catholic historian, and as such highly [illegible] to his liberality, conveys but a very [illegible] notion of the character of Elizabeth. [illegible] present day even the respect which attends [illegible] royal diadem would not for a moment have ensured the toleration of her licentious amours, and in many respects she closely resembled her royal namesake. It is evident that neither Elizabeth nor her ministers understood the benefit of civil and religious liberty. The prerogatives which she so highly prized, have long since withered away: the bloody code which she enacted against the rights of conscience, has ceased to stain the pages of the statute book: and the result has proved, that the abolition of despotism and intolerance adds no less to the stability of the throne, than to the happiness of the people.'

Elizabeth Petrowna, empress of Russia, was the second daughter of Peter the Great, and born in 1709. The testamentary disposition of this monarch was in favor of her succession to the throne, and she was urged to avail herself of the infancy of Ivan, who had been declared emperor under the regency of his father and mother, Anthony and Elizabeth of Mecklenburg. Her surgeon, Lestoff, seems to have decided her to assert her claim, by sending to her a picture, representing her on one side seated upon an imperial throne, and on the other beheaded on a scaffold. On the night of the 6th of December, 1741, she went to the quarters of the Preobashenki regiment of guards, who immediately declared her empress. A detachment accompanied her to the palace, where they arrested the regent prince and princess and the young Ivan; and by six o'clock in the morning she was proclaimed empress by a bloodless revolution. Elizabeth now became indolent and voluptuous. On her accession she made a vow never to inflict a capital punishment; and, resolving to pass her days unmarried, she nominated her nephew, Charles Peter Ulric (afterwards Peter III.) her successor. She, however, openly indulged in the most licentious amours, and her favorites, in fact, ruled her people. She is said to have had no fewer than eight natural children by them. With all this she was most scrupulously devout, and practised with great exactness all the ceremonies of her church. In 1756 Russia joined Austria and France against the king of Prussia; and the troops of the latter so hardly pressed upon him as to bring him to the brink of destruction, when the death of Elizabeth changed the entire prospect of affairs. This took place in December, 1761, in the fifty-second year of her age.

Elizabeth, in geography, a township of Pennsylvania, in Lancaster county, eighteen miles north-west by west of Lancaster, and eighty-four west by north of Philadelphia.

Elizabeth Cape, a cape on the island which forms the north-east point of the entrance into Cook's inlet. Vancouver describes this coast as composed of high land, before which lie three small islands and some rocks; the cape is itself the largest and the most western of these islands, which appear to afford a navigable channel between them and the main land, in an east and west direction; though between the cape and the middle island some low lurking rocks were discerned, which had the appearance of being connected with a cluster above the surface of the sea, lying south-east from the cape, at the distance of three or four miles; to the south-west of the middle island is another cluster of rocks, both above and beneath the water. Long. 208° 53′ E., lat. 59° 9′ N. Also a cape on the coast of Main.

Elizabeth Castle, a fortress of the island of Jersey, built on a rock in the east side of St. Aubin's Bay, which is insulated with the flowing of the tide. It is 663 paces distant from St. Heliers.

Elizabeth City, a county of Virginia, between the rivers James and York, bounded by Warwick and York counties on the west, and Chesapeake Bay on the east and north. It is

eighteen miles long, and eight broad. Point Comfort is the southern extremity of the county.

ELIZABETH ISLAND, an island in the straits of Magellan, near the shore of Patagonia. It was visited by Bougainville, who describes its coasts as high and steep. Water and wood are both scarce, and a small sort of heath is the only thing that can be used as fuel here. Long. 71° 45′ W., lat. 52° 50′ N.

ELIZABETH ISLANDS, sixteen small islands of Massachusetts, on the south-east side of Buzzard's Bay, extending south-west from Barnstaple county, and bearing north-west from Martha's vineyard. Cattahunk, Nashawn, Nashawenna, Pasqui, and Pinequese, are the chief of them. They belong to Duke's county, and lie between long. 70° 38′ and 70° 56′ W., and between lat. 41° 24′ and 41° 32′ N.

ELIZABETH RIVER, a river of the United States, the south head water of which rises from the Great Dismal Swamp, and running through Virginia falls into James River. A navigable canal was begun to be dug in 1797, to connect this river with the Pasquotank, which is fourteen miles distant. The canal company are incorporated by the legislatures of Virginia and North Carolina.

ELIZABETH-TOWN, a post town of New Jersey, in Essex county, seated on a rivulet which runs into Arthur Kull, six miles south of Newark, and fifteen south-west by west of New York. It is one of the oldest towns in the state, having been purchased of the Indians so early as 1664. It has two handsome churches, one for the Presbyterians and one for the Episcopalians; and is fifty-eight miles N. N. E. of Philadelphia, and twelve south-west by west of New York.

ELIZABETH-TOWN, a post town of Maryland, capital of Washington county, formerly called Hagar's Town, seated in the vale of Conecocheaque, six miles from the Potomac. It is regularly built, and has an Episcopalian, a Presbyterian, and a German Lutheran church; with a court house, gaol, &c. It carries on a good trade with the western county; and lies 175 miles west by south of Philadelphia, and fifty north-west of Baltimore.

ELK, *n. s.* Sax. ælc; Swed. *elg;* Goth. *alg;* Ital. and Span. *alce*, from Gr. *αλκη*, strength, according to Watcher. The moose deer.

The *elk* is a large and stately animal of the stag kind. The neck is short and slender; the ears nine inches in length, and four in breadth. The color of its coat in Winter is greyish, in Summer it is paler. The horns of the male *elk* are short and thick near the head, where it by degrees expands into a great breadth, with several prominences in its edges.
*Hill.*

And, scarce his head
Raised o'er the heapy wreath, the branching *elk*
Lies slumbering silent in the white abyss.
*Thomson.*

ELK, in zoology. See CERVUS.

ELK, in geography, a navigable river of the United States, on the eastern shore of Maryland, which rises in Chester county, Pennsylvania, and running S. S. W. thirty-three miles, falls into Chesapeake Bay, on the south side of Turkey Point.

ELK, a short navigable river in Tennessee, and Georgia, which rises in Tennessee, near the head waters of Duck River, and, running south-west, falls into the Tennessee at Muscle shoals.

ELKHORN RIVER, a river of Louisiana, which enters the La Plata about forty miles above its junction with the Missouri. It has a clear gravelly channel, and is about 100 yards wide at its mouth.

ELKRIDGE, a town of Maryland, United States, on the south bank of Patapsco River, eight miles north-west of Baltimore.

ELKTON, a town of Maryland, United States, at the head of Chesapeake Bay, and the capital of Cecil county. It is situated at the confluence of the head branches of the Elk, and enjoys considerable advantages from the carrying trade between Baltimore and Philadelphia. Thirty-seven miles south-west of Philadelphia.

ELL, *n. s.* Sax. eln (and frequently so written by our elder authors); Goth. *aul*, *aulin;* Swed. *aln;* Teut. *elle;* Belg. *el;* Lat. *ulna;* Gr. *ωλενη*. Both the last words, according to Vossius, being spoken of the arm as a measure of length. A measure containing in length one yard and a quarter.

The world produces for every pint of honey, a gallon of gall; for every dram of pleasure, a pound of pain; for every inch of mirth, an *ell* of moan; and as the ivy twines around the oak, so do misery and misfortune encompass the happiness of man.
*Burton.*

Acquit thee bravely, play the man;
Look not on pleasures as they come, but go;
Defer not the last virtue; life's poor span
Makes not an *ell* by trifling in thy woe. *Herbert.*

Upon their wedding-day Mr. Spectator and she had but half an *ell* of face betwixt them; and thy my very worthy predecessor, Mr. Serjeant Thin, always maintained to be no more than the true oval proportion between man and wife. *Spectator.*

They are said to make yearly forty thousand pieces of linen cloth, reckoning two hundred *ells* to the piece. *Addison.*

*The* ELL is a measure different in different countries, by which cloths, stuffs, linens, silks, &c., are usually measured. The ells most frequently used with us are the English and Flemish; the former containing three feet nine inches, or one yard and a quarter; the latter only twenty-seven inches, or three quarters of a yard; so that the ell English is to the Flemish ell as five to three. In Scotland the ell contains thirty-seven two-tenths English inches.

ELLAGIC ACID. The deposit which forms in infusion of nut-galls, left to itself, is not composed solely of gallic acid and a matter which colors it. It contains, besides, a little gallate and sulphate of lime, and a new acid, which was pointed out for the first time by M. Chevreul in 1815, an acid on which M. Braconnot made observations in 1818, and which he proposed to call acid ellagic, from the word galle, reversed. Probably this acid does not exist ready formed in nut-galls. It is insoluble; and, carrying down with it the greater part of the gallic acid, forms the yellowish crystalline deposit. But boiling water removes the gallic acid from the ellagic; whence the means of separating them from one another.

**ELLIPOMACROSTYLA**, in natural history, from ελλιπης, imperfect; μακρος, long; and στυλος, a column; q. d. an imperfect crystal with a long column; the name of a genus of crystals. The perfect figure of a crystal being a column, terminated by a pyramid at each end, those which want this character are esteemed imperfect: and accordingly the bodies of this genus are defined to be imperfect crystals with single pyramids; one end of their column being affixed to some solid body, and composed of thin and slender hexangular columns, terminated by hexangular pyramids. They are dodecahedral. Of these crystals authors enumerate many species, among which are the whitish pellucid sprig crystal, a bright brown kind, a dull brown kind, and a bright yellow kind; all which are farther distinguished according to the different lengths of their pyramids.

ELLIPOPACHYSTYLA, in natural history, from ελλιπης, imperfect; παχυς, thick; and στυλος, a column, q. d. an imperfect crystal with a thick column; a genus of crystals the bodies of which are composed of an hexangular column, considerably thick and short, affixed irregularly at one end to some solid body, and terminated at the other by an hexangular pyramid. There are two species, one short, bright, and colorless, found in great plenty in New Spain, and other parts of America; the other, a short, dull, and dusky brown one, found in Germany, and sometimes in England.

ELLIPSE, or ELLIPSIS, in geometry. See CONIC SECTIONS.

ELLIP'SIS, *n. s.*
ELLIP'TIC, *adj.*
ELLIP'TICALLY, *adv.*
} Fr. *ellipse;* Italian *elisse;* Span. and Port. *elipse,* from Gr. ελλειπσις (from εκ out, or emphat. and λειπω, to fail, Parkhurst). A figure of speech whereby something implied in a sentence is omitted: one of the conic sections, called also an oval; but originally termed an ellipse or ellipsis by Apollonius, because in this figure the squares of the ordinates are less than, or defective in, the rectangles, under the parameters and abscisses.

The words are delivered by way of *ellipsis*, Rom. iv. 18. *Hammond.*

The planets could not possibly acquire such revolutions in circular orbs, or in *ellipses* very little eccentrick. *Bentley.*

On the cylinder inclined, describe an *ellipsis* parallel to the horizon. *Wilkins's Dædalus.*

Since the planets move in *elliptick* orbits, in one of whose foci the sun is, and by a radius from the sun describe equal areas in equal times, which no other law of a circulating fluid, but the harmonical circulation, can account for; we must find out a law for the paracentrical motion, that may make the orbits *elliptick.* *Cheyne's Phil. Prin.*

In animals, that gather food from the ground, the pupil is oval or *elliptical*; the greatest diameter going transversely from side to side. *Id.*

Earths round each sun with quick explosions burst,
And second planets issue from the first;
Bend, as they journey with projectile force,
In bright *ellipses* their reluctant course. *Darwin.*

ELLIS (George), F. R. S. and F. S. A., an ingenious miscellaneous writer, was born in London in 1745, and educated at Westminster school. He afterwards went to Trinity College, Cambridge, and was one of the writers of the celebrated 'Rolliad,' a satirical publication against the administration of Mr. Pitt; but he afterwards became attached to that statesman, and was appointed secretary to lord Malmesbury, on the embassy to Lisle. Mr. Ellis died in 1815. His works are: 1. Specimens of the Early English Poets, 3 vols. 8vo. 2. Preface, Notes, and Appendix, to a Translation of Le Grand's Fabliaux, 2 vols. 8vo. 3. Specimens of English Metrical Romances, 3 vols. 8vo.

ELLIS (John), F. R. S., a zoological and botanical writer, was born in London about 1710; and, applying himself very early in life to scientific observations, discovered the animal nature of corals and corallines, on which subject he published an Essay, 4to. in 1755. He distinguished himself in botany by an account of new plants from America; a description of the Confervæ, and a dissertation on the Varnish Tree of Japan. He also wrote an account of Coffee, a description of the Mangostan and Bread Fruit, and Directions to Voyagers for bringing home Vegetable Productions. He was also the author of various papers in the Transactions of the Royal Society. Lord chancellor Northington gave him the place of agent for West Florida and Dominica. He died in 1776. His Natural History of uncommon Zoophites, was published by his daughter.

ELLISIA, in botany, a genus of the monogynia order, pentandria class of plants, natural order twenty-eighth, luridæ: COR. monopetalous and funnel-shaped; the berry carnous and bilocular: SEEDS two, muricated or set with small raised points, the one higher than the other. Species one only, an annual of Virginia.

ELLORE, or ELURA, one of the northern Circars of Hindostan, is situated between 16° and 17° of N. lat. Ellore and Condapilly occupy the whole of the space between the Krishna and the Godavery. Its superficial contents are estimated at 2700 square miles, exclusive of the high mountainous region on the west. The principal towns are Ellore, Colaircotta, and Gundgoli.

ELLORE, the capital of the above district, is situated on the northern side of the Colair Lake, through which it has lately been proposed to carry a canal from the Godavery to the Kistnah. It possesses a small fort, and formerly had a military cantonment in its vicinity.

ELLSMERE, a market town of Shropshire, sixteen miles north-west of Shrewsbury, and 169 north-west from London. Its principal traffic is in malt, the culture of barley being particularly attended to in its neighbourhood. It derives its name from an extensive lake, or mere, covering 100 acres, and exceedingly well stocked with fish, and its banks ornamented with a well-built town on one side, and the mansion and park, called Oatley, on the other. From the Castle-hill, on which there is one of the finest bowling-greens in the kingdom, there is a distinct view of nine different counties. The church has a square tower, with eight bells. Market on Tuesday.

ELLWANGEN, once the capital of a distric

of this name, is now the chief town in the department of the Kocher, in the kingdom of Wirtemberg, and situated in a pleasant valley on the Jaxt. It is small, but well built, and contains 2100 inhabitants. The catholic university here has been united with the protestant one of Zubingen. Thirty-two miles north of Ulm.

ELLWOOD (T.), an early quaker, and an associate of Milton the poet, published, in his twenty-second year, An Alarm to the Priests on a Message from Heaven to warn them. In 1665 he lodged with Milton at Chalfont, Bucks, and became the occasion of his writing Paradise Regained, by observing, on the return of the Paradise Lost, which the poet had lent him to read, 'Thou hast said much of Paradise lost, but what hast thou to say of Paradise found?' The life of Mr. Ellwood was almost wholly spent in controversy, and his zeal and perseverance in his opinions rendered him constantly liable to the conventicle, and other persecuting laws. In 1705 he published the first part of Sacred History, or the Historical Parts of the Old Testament; and in 1709 Sacred History, &c., of the New Testament. His other works are numerous; one of them, entitled The Foundation of Tithes Shaken, attracted much attention at the time. He also published Davideis, the Life of David, King of Israel, a poem; and died in 1713, aged seventy-four. His life, written by himself, affords several interesting particulars of the early history of his sect.

ELM, *n. s.* } Sax. elm; Fr. *ulme*, and *orme*;
ELM'Y, *adj.* } Lat. *ulmus*. A tree, formerly used to support the vine. See ULMUS.

> Thou art an *elm*, my husband; I a vine;
> Whose weakness married to thy stronger state,
> Makes me with thy strength to communicate.
> *Shakspeare.*

> The rural seat,
> Whose lofty *elms* and venerable oaks,
> Invite the rook, who high amid' the boughs,
> In early Spring, his airy city builds. *Thomson.*

> Through the sandy soil
> Of *elmy* Ross or Devon's myrtle groves.
> *Dyer. Fleece.*

> The simple spire and *elmy* grange. *T. Warton.*

> Round the tall *elm* the flattering ivies bend,
> And strangle, as they clasp, their struggling friend.
> *Darwin.*

ELM, in botany. See ULMUS. The elm is a timber of peculiar property and singular use in situations where it is continually exposed either to the wet, or to be kept dry. Its grain being rough and curly, causes it to be not liable to split. If felled between the months of November and February, it is found to have no sap, and is of peculiar service in mast-making.

ELMACINUS (George), author of a History of the Saracens, was born in Egypt towards the middle of the thirteenth century. His history begins with Mahomet, and continues to the year of the hegira 512, answering to A. D. 1134; in which he sets down year by year, in a very concise manner, whatever regards the Saracen empire, intermixed with some passages relating to the eastern Christians. He was son to Yaser Al Amid, secretary to the council of war under the sultans of Egypt for forty-five years; and in 1238, when his father died, succeeded him in his place, though professing Christianity. His history of the Saracens was translated from Arabic into Latin by Erpinius; and printed in these two languages in folio, at Leyden, in 1625. Erpinius died before the publication.

ELMINA, or ST. GEORGE DEL MINA, the capital of the Dutch settlements on the Gold Coast of Africa, and one of the most respectable fortresses in that neighbourhood, was built originally by the Portuguese, who made it the capital of their settlements upon this coast in 1481. In 1637 it was taken by the Dutch, and ceded to them afterwards by treaty. From this time the Dutch claimed the sole dominion of the Gold Coast, but were soon forced by the English to resign that pretension.

Elmina stands on a peninsula, formed by a small river running nearly parallel with the sea, and the castle has two approaches, one from the town, where it is strengthened by a double ditch, over which are drawbridges; the other adjoining the river, where is a small gate, at an elevation of about twelve feet, to which an ascent is formed by a steep ladder. A fort is built on an eminence adjoining named Conradsburg or St. Jago, and this may be considered the key of Elmina. The town is large and dirty, and the river, though small, will admit vessels of 100 tons burden at high water. It repulsed a respectable English force in 1781; but this is attributed to a want of concert between the commanders. The surrounding country is, for the most part, open and flat, and the soil light, though, in some places, of a heavy clay. The inhabitants consist of traders, fishermen, and persons employed as servants to traders; some among them are wealthy. There are likewise many mulattoes in respectable circumstances here, who support a number of slaves, performing the duties of carpenters, masons, and blacksmiths. The place is supposed, altogether, to contain 15,000 inhabitants. In 1808 the Dutch governor was killed in a conspiracy; but he is said to have been a very turbulent and imprudent man. During the invasion of the Ashantees, the inhabitants of Elmina favored that people, and delivered up to them some of the Fantees who fled to the place. The Fantees, on this, assembled afterwards in great force, but were unable to make any impression upon Elmina. Its trade, previous to these disturbances, was brisk, consisting in slaves and gold, with a little ivory, brought from the interior. Long. 2° 30′ W., lat. 5° 10′ N.

ELMSLEY (Peter), a learned divine and philologist, was born in London in 1773, and educated at Westminster school, whence he removed to Christ Church, Oxford, and took the degree of M. A. in 1797. Soon afterwards he entered into orders, and was presented to the chapelry of Little Horkesley in Essex, but is said to have bestowed all its emolument on his curate. Mr. Elmsley had a respectable private fortune, and after the peace of 1815 went to Italy, and was employed with Sir Humphry Davy in superintending the development of the papyri found at Herculaneum. To Mr. Elmsley was left the choice of the MSS. but the experiment proved

a failure. He settled at Oxford on his return, and took the degree of D. D. In 1823 he was appointed principal of Alban Hall, and Camdenian professor of History; but died of a decline in 1825. Dr. Elmsley was the editor of some of the plays of Euripides and Sophocles, and a writer in the Quarterly Review.

ELOCA'TION, *n. s.* Lat. *elocatus* (*e*, out, and *locare*, to place.) Placing out or from home.

This may without sin or blame be forborne—when the child either by general permission or former *elocation* shall be out of the parents' disposing. *Bp. Hall.*

ELOCU'TION, *n. s.* } Fr. *elocution*; Ital. ELOCU'TIVE, *adj.* } *elocutione*; Span. *elocucion*; Lat. *elocutio* (*e*, out and *loquor* to speak). Fluent or forcible speech; the power or faculty of using fluent speech.

A travelled doctor of physick, of bold, and of able *elocution*. *Wotton.*

Whose taste, too long forborne, at first essay
Gave *elocution* to the mute, and taught
The tongue not made for speech to speak thy praise. *Milton.*

Preaching in its *elocutive* part is but the conception of man. *Feltham.*

The third happiness of this poet's imagination is *elocution*, or the art of cloathing or adorning that thought so found, and varied, in apt, significant, and sounding words. *Dryden.*

And again, as she is a lady of very fluent *elocution*, you need not fear that your first child will be born dumb, which otherwise you might have some reason to be apprehensive of. *Spectator.*

ELOCUTION. See ORATORY.

EL'OGY, *n. s.* } French *eloge*, and *elogiste*; EL'OGIST. } Span. Port. and Ital. *elogio*; Lat. *elogium*; Gr. ευλογια (ευ and λεγειν, to speak well.) A commendatory speech often used synonymously with, and having the same etymology as eulogium; but often also applied in a more general sense.

She did not want a passionate *elogist* as well as an excellent preacher. *Wotton.*

Buckingham lay under millions of maledictions, which at the prince's arrival did vanish into praises and *elogies*. *Wotton.*

If I durst say all I know of the *elogies* received concerning him, I should offend the modesty of our author. *Boyle.*

Some excellent persons, above my approbation or *elogy*, have considered this subject. *Holder's Elements of Speech.*

E'LOIGNE, *v. a.* Fr. *eloigner*. To put at a distance; to remove one far from another. Now disused.

From worldly care himself he did *eloin*,
And greatly shunned manly exercise. *Faerie Queene.*

I'll tell thee now, dear love! what thou shalt do
To anger destiny, as she doth us;
How I shall stay though she *eloigne* me thus,
And how posterity shall know it too. *Donne.*

ELON, the twelfth judge of Israel, and the second after Jephthah, succeeded Ibzan, about A. M. 2830; or, according to Alstedius, 2771. He was of the tribe of Zebulon, and, after governing the republic ten years, died about A.A.C. 1167.

ELONG' *v. a.* } Old Fr. *ehlon-* ELONG'ATE, *v. a.* & *v. n.* } *ger* (to delay); ELONGA'TION, *n. s.* } Sax. lengian, to prolong; Lat. *elongo*. To defer; protract; set far off, in place or time. Elongate, as a neuter verb, means to go off to a distance.

The distant points in the celestial expanse appear to the eye in so small a degree of *elongation* from another, as bears no proportion to what is real. *Glanville's Scepsis.*

The first star of Aries, in the time of Meton the Athenian, was placed in the very intersection, which is now *elongated* and moved eastward twenty-eight degrees. *Browne.*

About Cape Frio in Brasilia, the south point of the compass varied twelve degrees unto the west; but *elongating* from the coast of Brasilia, towards the shore of Africa, it varied eastward. *Id. Vulgar Errours.*

Upon the roof the bird of sorrow sat,
*Elonging* joyful day with her sad note,
And through the shady air the fluttering bat
Did wave her leather sails. *G. Fletcher.*

To this motion of *elongation* of the fibres, is owing the union or conglutination of the parts of the body, when they are separated by a wound. *Arbuthnot on Aliments.*

*Elongations* are the effect of a humour soaking upon a ligament, thereby making it liable to be stretched, and to be thrust quite out upon every little force. *Wiseman's Surgery.*

ELONGATION, in astronomy, the digression or recess of a planet from the sun, with respect to an eye placed on our earth. The term is chiefly used in speaking of Venus and Mercury; the arc of a great circle intercepted between either of these planets and the sun being called the elongation of that planet from the sun.

ELOPE' *v. a.* } Sax. hleapan; Belg. ELOPE'MENT, *n. s.* } *loopen*; Swedish, *lopa*; Goth. *leipa*; Gr. λειπω, to leave. To run away or off from: to escape from; forsake. Applied particularly to the running away of husband or wife with a mistress or lover.

An *elopement* is the voluntary departure of a wife from her husband to live with an adulterer, and with whom she lives in breach of the matrimonial vow. *Ayliffe's Parergon.*

It is necessary to treat women as members of the body politic, since great numbers of them have *eloped* from their allegiance. *Addison's Freeholder.*

What from the dame can Paris hope?
She may as well from him *elope*. *Prior.*

The negligent husband, trusting to the efficacy of his principle, was undone by his wife's *elopement* from him. *Arbuthnot.*

The fool whose wife *elopes* some thrice a quarter,
For matrimonial solace dies a martyr. *Pope.*

Is he not thine own,
Thyself in miniature, thy flesh, thy bone?
And hopest thou not ('tis every father's hope)
That, since thy strength must with thy years *elope*,
And thou wilt need some comfort to assuage
Health's last farewell, a staff in thine old age,— *Cowper.*

*An* ELOPEMENT, in law, frees the husband from an obligation to allow the adulteress any alimony out of his estate; nor is he chargeable for necessaries for her of any kind. However, the bare advertising a wife in the gazette, or other public paper, is not a legal notice to persons in general not to trust her; though a personal no-

tice given by the husband to particular persons is said to be good.—An action lies, and large damages may be recovered against a man for carrying away and detaining another man's wife.

ELOPS, *n. s.* Gr. ἔλοψ. A fish. See ACCIPENSER; reckoned, however, by Milton among the serpents.

Scorpion and asp, and amphisbena dire,
Cerastes horned, hydrus, and *elops* drear,
And dipsas. *Milton's Paradise Lost.*

EL'OQUENCE, *n. s.*
EL'OQUENT, *adj.*
EL'OQUENTLY, *adv.*
Latin, *eloquentia.* See ELOCUTION. The act or power of speaking well or fluently: the adjective and adverb strictly follow this meaning.

The Lord of hosts doth take away the captain of fifty, and the honorable man, and the counsellor, and the cunning artificer, and the *eloquent* orator. *Isaiah*, iii. 3.

Action is *eloquence*, and the eyes of the ignorant
More learned than the ears. *Shakspeare. Coriolanus.*

Athens or free Rome, where *eloquence*
Flourished since mute. *Milton.*

At the New Exchange they are *eloquent* for the want of cash, but in the city they ought with cash to supply their want of *eloquence.* *Spectator.*

*Eloquence* must flow like a stream, that is fed by an abundant spring, and not spout forth a little frothy water on some gaudy day, and remain dry the rest of the year. *Bolingbroke.*

His infant softness pleads a milder doom,
And speaks with all the *eloquence* of tears. *Heigh.*

True *eloquence* is good sense, delivered in a natural and unaffected way, without the artificial ornament of tropes and figures. *Baker.*

O death! all *eloquent*, you only prove
What dust we dote on, when 'tis man we love.
*Pope.*

Fit words attended on his weighty sense,
And mild persuasion flowed in *eloquence.*
*Id. Odyssey.*

Great is the power of *eloquence*; but never is it so great as when it pleads along with nature. *Sterne.*

And on that cheek, and o'er that brow,
So soft, so calm, yet *eloquent*,
The smiles that win, the tints that glow,
But tell of days in goodness spent. *Byron.*

ELOQUENCE. See ORATORY.

ELORA, or ELURA, a town in the province of Aurungabad, near Dowletabad, Hindostan, and named on the spot Verrool. About a mile to the east of this town are some remarkable excavations in a mountain, consisting of Hindoo temples and mythological symbols, which in magnitude, and perfection of execution, excel any thing of the kind in India. They are described at great length in the sixth volume of the Asiatic Researches, and appear to have been dedicated to Siva or Mahadeva. The brahmins on the spot assert that they were formed by Eeloo, rajah of Ellichpoor 7914 years ago. The rajah's successors probably added other temples; and the cistern still retains its fame and sanctity, under the appellation of Sewalla koond. This, with the temple, is one of the many objects of Hindoo pilgrimage. Long. 76° 0' E., lat. 19° 56' N.

ELPHINSTONE (William), a Scottish prelate and distinguished statesman, was born at Glasgow in 1431, and received his education at the university of that city. After which he went over to France, for the purpose of attaining a perfect knowledge of the civil and canon law, in the university of Paris, where he afterwards became a professor. Returning to Scotland, he entered into holy orders, was soon appointed official of Glasgow, and afterwards of St. Andrews. He was admitted a member of the king's council, and soon after promoted to the see of Ross. He was translated from this to the diocese of Aberdeen about the year 1484, and was also appointed to the high office of chancellor of the kingdom. When James IV. ascended the throne he was chosen ambassador to the emperor Maximilian, and he was the means of terminating an enmity which had long existed between the Dutch and Scotch. The bishop was no less the zealous patron of learning; and it was through his influence that James IV. applied for and obtained a bull from the pope for the establishment of a university at Aberdeen. King's College, of which he is generally considered as the founder, was undertaken and completed by his exertions; and at his death he bequeathed large sums of money for its support. He died in 1514, in the eighty-third year of his age. He wrote a history of Scotland, which is among the MSS. of Sir Thomas Fairfax, in the Bodleian library at Oxford.

ELSE, *pron.* & *conj.*
ELSE'WHERE, *adv.*
Saxon, elleꞅ, alyꞅ; Goth. *alia, ellar, elegar*; Dan. *ellers*; Swed. *eller, ællas.* According to Mr. H. Tooke, the Saxon words elleꞅ and alyꞅ are the imperative of aleꞅan and alyꞅan, to dismiss. Other one besides; otherwise. Elsewhere, is in any other place.

And no man putteth newe wyn into olde botels, *ellis* the wyn schal berste the botels.
*Wiclif. Mark* 2.

But I would now,
Comen with you,
In counsayle yf you please,
Or *ellys* not
Of matters that
Shall set your heart at ease.
*Sir T. More.*

They which *elsewhere* complain, that injury is offered to the meanest minister, when the magistrate appointeth him what to wear, think the gravest prelates no competent judges where it is fit for the minister to stand. *Hooker.*

In forming a judgment, lay your hearts void of foretaken opinions; *else* whatsoever is done or said will be measured by a wrong rule. *Sir P. Sidney.*

To stand stained with travel, and sweating with desire to see him; thinking of nothing *else*, putting all affairs *else* in oblivion, as if there were nothing *else* to be done but to see him.
*Shakspeare. Henry IV.*

As he proved that Pison was not Ganges, or Gehon, Nilus, so where to find them *elsewhere* he knew not.
*Raleigh's History.*

There are here divers trees, which are not to be found *elsewhere.* *Abbot's Description of the World.*

He says, 'twas then with him, as now with you,
He did it when he had nothing *else* to do. *Denham.*

Let us no more contend nor blame
Each other, blamed enough *elsewhere.* *Milton.*

Should he or any *else* search, he will find evidence of the Divine Wisdom. *Hale's Origin of Mankind.*

They rub the frozen parts with snow, or *else* cast the whole body into water, by which means the whole body is crusted over with ice.
*Boyle. An account of Freezing, made in* 1662.

What ways are there whereby we should be assured, but either by an internal impression of the notion of a God upon our minds, or *else* by such external and visible effects as our reason tells us must be attributed to some cause. *Tillotson.*

If it contradict what he says *elsewhere*, it is no new or strange thing. *Id.*

None ever was a great poet that applied himself much to any thing *else*. *Sir W. Temple.*

Bestow, base man, thy idle threats *elsewhere* ;
My mother's daughter knows not how to fear.
*Dryden.*

The fool is blind to those blemishes in his character which are conspicuous to every body *else*.
*Mason.*

ELSHEIMER (Adam), a celebrated painter, born at Frankfort on the Maine in 1574. He was first a disciple of Philip Uffenbach a German; but going to Rome he soon became celebrated for landscapes, history, and night-pieces, with small figures. His works are but few; and the great pains he bestowed in finishing them raised their prices so high that they are seldom to be found but in the cabinets of princes. He was of a melancholy turn, and sunk under the embarrassments of his circumstances, in 1610. James Ernest Thomas, of Landau, was his disciple; and imitated his style so nicely, that their performances are not easily distinguished.

ELSIMBURG, or Helsimburg, a port town of Sweden, in the province of Gothland, and territory of Schonen, seated on the side of the Sound, seven miles east of Elsinore. It was formerly a fortress belonging to the Danes; but all the fortifications were demolished in 1679, and there is only one tower of a castle which remains undemolished. Long. 13° 20′ E., lat. 56° 2′ N.

ELSINEUR, Elsinoor, Elsinore, or Helsingoer, a port town of Denmark, seated on the Sound, in the isle of Zealand, twenty miles north of Copenhagen. It was a small village, containing a few fishermen's huts, until 1445, when it was made a staple town by Eric of Pomerania; who conferred upon the new settlers considerable immunities, and built a castle for their defence. From that period it gradually increased in size and wealth, and is now the most commercial place in Denmark, next to Copenhagen. It contains about 7000 inhabitants, amongst whom are a considerable number of foreign merchants, several British establishments, and the consuls of the principal nations trading to the Baltic. The passage of the Sound is guarded by the fortress of Cronborg, which is situated upon the edge of a peninsular promontory, the nearest point of land from the opposite coast of Sweden. It is strongly fortified towards the shore by ditches, bastions, and regular intrenchments; and toward the sea by several batteries; but it was found, in 1801, incapable of resisting the passage of a fleet. Every vessel, as she passes, lowers her top-sails, and pays a toll of one per cent. on the value of her cargo at Elsineur. The product of the toll has been differently stated; it varies from £120,000 to £150,000 sterling. The number of vessels is estimated at about 10,000; and one and a quarter per cent. is said to be levied on all vessels but the British, French, Dutch, and Swedish.

ELSTER, the name of two rivers of Germany, one of which, called the White Elster, rises in the south of Saxony, and holding a northern course, near Leipsic, falls into the Saale. A considerable pearl-fishery is carried on on its banks near Oelsnits. The Black Elster rises to the eastward in Lusatia, and, after a northeasterly course, falls into the Elbe six miles above Wittenburg. Near the influx of this river Blucher crossed the Elbe on the 3rd October 1813, and marched to the memorable battle of Leipsic.

ELSTOB (William), a celebrated Saxon scholar and critic of the last century, was born at Newcastle in 1673, and received his education at Eton, at Catherine Hall, Cambridge, and subsequently at Queen's College, Oxford, whither he removed for the sake of his health. He obtained a fellowship in 1696, and was admitted M. A. in the following year. In 1701 he translated the Saxon homily of Lupus into Latin, with notes, and was soon after appointed rector of the united parishes of St. Swithin and St. Mary Bothaw, London. In 1709 he published The Homily on St. Gregory's Day, in Saxon, with a Latin translation; and died in 1714. He had formed the design of publishing a collection of the laws of the Anglo-Saxons, with a Latin version and notes of various authors. He had also transcribed the Anglo-Saxon translation of Orosius, by Alfred the Great, a specimen of which was printed in 1699, under the title of Hormesta Pauli Orosii. He left a learned sister, Elizabeth Elstob, who published a Saxon grammar.

ELVAS, one of the most important towns of Portugal, is situated in the province of Alentejo, a few miles from the frontiers of Spanish Estremadura. It is built on a mountain, and fortified. The streets were once handsome, and the houses neat; but the whole place has a decayed appearance. There is a cistern here so large that it will hold water enough to supply the whole town six months. It is conveyed to it by a magnificent aqueduct, three miles in length, sustained in some places by four or five high arches, one upon another. Elvas was bombarded by the French and Spaniards in 1706, but without effect. It has generally a garrison of 1000 men, and the population is about 16,000. The king founded an academy here, in 1733, for young gentlemen. Elvas is seated near the Guadiana; fifty miles north-east of Evora, and 100 east of Lisbon.

ELU'CIDATE, *v. a.*
Elucida'tion, *n. s.*
Elu'cidator.
} Fr. *elucider* ; Latin, *elucido* ; *e* and *lucido*, to shine. To make clear, bright, or plain.

Obscurity is brought over them by the course of ignorance and age, and yet more by their pedantical *elucidators*. *Abbot.*

To *elucidate* a little the matter, let us consider it. *Boyle.*

We shall, in order to the *elucidation* of this matter, subjoin the following experiment. *Id.*

ELUCTATION, *n. s.* Lat. *eluctatus, eluctari*. A bursting or struggling forth; escape.

There is nothing more acceptable to the ingenious, than this noble *eluctation* of truth. *Browne.*

ELUDE', *v. a.* } Lat. *eludo; e*, and *ludo*,
ELUD'IBLE, *adj.* } to deceive. To escape
ELU'SION, *n. s.* } from, by stratagem: elu-
ELU'SIVE, *adj.* } dible is possible, or likely,
ELU'SORY. } to be eluded; elusion, escape by artifice or fraud; elusive and elusory, deceptive, tendency to impose upon or cheat.

It may be feared that they are but Parthian flights, ambuscade retreats, and *elusory* tergiversation.
*Browne's Vulgar Errours.*

The passion of some lovers is such that it *eludes* the rigor of their fortune, and baffles the force of a blow, which neither feels, because each receives it for the sake of the other. *Tatler.*

Several pernicious vices, notorious among us, escape or *elude* the punishment of any law yet invented.
*Swift.*

There is not any common place more insisted on than the happiness of trials by juries; yet, if this blessed part of our law be *eludible* by power and artifice, we shall have little reason to boast. *Id.*

An appendix, relating to the transmutation of metals, detects the impostures and *elusions* of those who have pretended to it. *Woodward's Nat. Hist.*

He who looks no higher for the motives of his conduct than the resentments of human justice, whenever he can presume himself cunning enough to *elude*, rich enough to bribe, or strong enough to resist it, will be under no restraint. *Rogers.*

Me gentle Delia beckons from the plain,
Then, hid in shades, *eludes* her eager swain;
But feigns a laugh to see me search around,
And by that laugh the willing fair is found.
*Pope.*

*Elusive* of the bridal day, she gives
Fond hopes to all, and all with hopes deceives.
*Id.*

But the king's eagerness to obtain liberty *eluded* all their vigilance. *Robertson. Hist. of Scotland.*

Whilst Amaryllis turns with graceful ease
Her blushing beauties, and *eludes* the breeze.—
Sylphs! if at noon the fritillary droops,
With drops nectareous hang her nodding cups.
*Darwin.*

ELVELA, in botany, a genus of the natural order of fungi belonging to the cryptogamia class of plants. The fungus is turbinated, or like an inverted cone.

ELUTE, *v. a.* Lat. *eluo*. To wash off.

The more oily any spirit is, the more pernicious; because it is harder to be *eluted* by the blood.
*Arbuthnot on Aliments.*

ELUTRIATE, *v. a.* Lat, *elutrio*. To decant, or strain out.

The pressure of the air upon the lungs is much less than it has been computed by some; but still it is something, and the alteration of one-tenth of its force upon the lungs must produce some difference in *elutriating* the blood as it passes through the lungs.
*Arbuthnot on Air.*

Though coal and clay are frequently produced in this manner, yet I have no doubt but that they are likewise often produced by *elutriation*. *Darwin.*

ELUTRIATION, in chemistry, an operation performed by washing solid substances with water, stirring them well together, and hastily pouring off the liquid, while the lighter part remains suspended in it, that it may thereby be separated from the heavier part. By this operation metallic ores are separated from earth, stones, and other unmetallic particles adhering to them.

ELY, a city of England, in the county of Cambridge, situated on the river Ouse, in a marshy district called the Isle of Ely. Its Saxon name was Suth Gurwa, but, according to Bede, it obtained the name Elig, or Elye, from the abundance of eels produced in the fens and waters of the neighbourhood. It consists of one principal street, and some smaller and very irregular ones. Its chief interest, as a city, is derived from its venerable Anglo-Norman cathedral, which extends in length 517 feet, having a tower at the west end 270 feet in height. Ely was first constituted a bishopric in the year 1109. The cathedral is clearly the work of different ages, and displays a curious mixture of the circular, and the English or pointed, styles of architecture. That part of the tower which is termed the Lantern is particularly admired. This is the only city of England not represented in parliament. Mr. Bentham's celebrated description of the cathedral is one of the most elegant works of the kind in our language. Here is a free school supported by the dean and chapter, and a charity school founded in the last century. The neighbourhood is productive, and laid out very largely in garden-ground. The market is weekly, and there are two annual fairs. It is fourteen miles north of Cambridge, and sixty-six north of London.

The Isle of Ely is a royal franchise, in which the bishop of this diocese exercises a civil jurisdiction, which extends to his appointment of a judge of assize and the other magistrates; so that the twelve judges of England have no circuit or jurisdiction here. When a special commission was issued, some few years ago, to try some rioters at Ely, it was found that the king could grant no legal power to try offences within the isle, apart from the bishop, whose chief justice was therefore included in the commission. Strictly speaking the Isle of Ely, according to Bentham, is that large tract of highland encompassed with fens, which were formerly overflowed with water, of which Ely is the principal place, and gives name to the whole: in which are included also the villages of Stretham and Thetford, Wilburton, Hadenham, Sutton, Mepal Wenham, Wentford, Whichford, Downham, and Chetisham, making collectively but one island. Littleport, Covenay, and Stretney, though sometimes reckoned part of it, were in their original state disjoined by small intervals of fenny ground, and therefore were distinct islands of themselves. This tract is about seven miles in length, and four in breadth. 'But the whole district now called the Isle of Ely, extends from the bridge at Tyd on the north to Upwere on the south, twenty-eight miles in length; and from Abbot's or Bishop's Delf on the east, to the river Nene, near Peterborough, on the west, twenty-five miles in breadth. This district, besides the places above mentioned, includes several considerable towns and villages, as Wisbeach, Whittlesey, Doddington, March Leverington, Newton, Chatteris, &c.

ELY, ELIE, or ELLIE, from a liche, Gaelic, i. e. out of the sea; an ancient royal borough, in

parish of the same name, on the south coast of Fife, built so near the sea that it washes the walls in some places, and seems to threaten to resume what it gave, if tradition be true, that the town was originally built out of it. It has an excellent harbour, the deepest in the Frith, except that of Brunt Island. It has been the means of saving many a ship, cargo, and seaman, that would otherwise have been driven out of the Frith. Vessels of considerable size are built; and manufactures of checks, bedticks, and ropes, are carried on in Ely. Rubies have been found on the shore.

ELYDORIC PAINTING, from ἔλαιον oil, and ὕδωρ, water; in the fine arts is a method of painting in a vehicle composed of oil and water. This method was invented by M. Vincent, of Montpetit. It takes its name from the before quoted Greek words, denoting oil and water, both these liquids being employed in its execution. Its principal advantages are, that the artist is able to add the freshness of water-colors, and the high finishing of miniature, to the mellowness of oil-painting, in such a manner that the work appears like a large picture seen through a concave lens.

The following is the manner of proceeding: a piece of very fine linen, or white taffety, is sized with starch in the most equal manner possible, on pieces of glass about two inches square, in order that the cloth may be without wrinkles. When these are sufficiently dry, a layer of white lead, finely ground in oil of pinks or poppies, the whitest that can be procured, is to be applied on them with a pallet-knife. To this layer, when dry enough to admit of scraping, more is to be added, if necessary.

As it is of very great importance, for the preservation of this kind of painting, that the layers be free from oil, that they may better imbibe the colors laid on them, it is necessary that their surface be made very smooth, and that it be very dry and hard. The artist is next to procure a circle of copper, about two inches diameter and one-fourth of an inch in height, extremely thin, and painted black on the inside. This circle is to contain the water on the surface of the picture.

Water distilled from rain or snow is preferable to any other; ordinary water, on account of the salts which it contains, being pernicious to this mode of painting. The colors are to be finely levigated between two oriental agates, carefully preserved from dust, and mixed with oil of poppies, or any other cold siccative oil which should be as limpid as water.

All the colors being ground, are to be placed in small parcels on a piece of glass, and covered with distilled water. The materials being thus prepared, the subject to be painted is to be faintly traced with a black-lead pencil on one of the pieces of cloth abovementioned. The tints are then to be formed on the pallet from the little heaps under the water; and the pallet placed, as usual, in the left hand. The picture is to be held between the thumb and fore-finger, supported by the middle finger, and the necessary pencils the third and little fingers. The hands rest on the back of a chair to give a full liberty of bringing the work nearer to, or removing it far from the eye.

After having made the rough draft, with the colors still fresh, the circle of copper, which is to surround the picture, is to be fitted exactly to the surface. Distilled water is then poured within this circle till it rises to the height of one-eighth of an inch, and the eye is held perpendicular over the object. The third finger of the right hand, while painting, should rest on the internal right angle of the picture. The work is then to be retouched, the artist adding color and softening as he finds requisite. As soon as the oil swims on the top, the water is poured off, and the picture carefully covered with a watch-glass, and dried in a box by a gentle heat. When dry enough, it is to be scraped nearly smooth with a knife, the artist repeating the former method till he is satisfied with his work.

It is at this period that the advantage of this new method particularly shows itself for the purpose of finishing; as the water poured on the picture discovers every fault of the pencil, and gives the power of correcting and perfecting it with certainty. When the work is finished, it is put under a fine glass, from which the external air is excluded, and then it is dried by means of a gentle heat.

ELYMAIS, the capital of Elam, or Persia. We are told, 1 Mac. vi. 1, that Antiochus Epiphanes, having understood that there were very great treasures lodged in a temple at Elymais, determined to plunder it; but the citizens, getting intelligence of his design, made an insurrection, forced him out of the city, and obliged him to fly. The author of the second book of Maccabees, ix. 2, calls this city Persepolis, in all probability because formerly it was the capital of Persia; for it is known, from other accounts, that Persepolis and Elymais were two very different cities, the latter situated upon the Eulæus, the former upon the Araxes.

ELYMUS, in botany, a genus of the digynia order and triandria class of plants: CAL. lateral, bivalved, aggregate, and multiflorous. Species twelve, of which three are common in England.

ELY'SIUM, *n. s.* } Lat. See the article.
ELY'SIAN, *adj.* } The place assigned by the heathens to happy souls; any place exquisitely pleasant.

> To have thee with thy lips to stop my mouth,
> So should'st thou either turn my flying soul,
> Or I should breathe it so into thy body,
> And then it lived in sweet *Elysium*.
> *Shakspeare. Hen. VI.*
>
> The river of life, through midst of heaven,
> Rolls o'er *elysian* flowers her amber stream. *Milton.*
>
> Pleasures which no where else were to be found,
> And all *Elysium* in a spot of ground. *Dryden.*
>
> Admiring Proserpine through dusky glades
> Led the fair phantom to *Elysian* shades,
> Clad with new form, with finer sense combined,
> And lit with purer flame the ethereal mind.
> *Darwin.*
>
> O who of man the story will unfold,
> 'Ere victory and empire wrought annoy,
> In that *elysian* age, misnamed of gold,
> The age of love, and innocence, and joy,
> When all were great and free! man's sole employ
> To deck the bosom of his parent earth. *Beattie.*

ELYSIUM, Ἠλύσιος, in the ancient mythology, was represented as a place in the inferi, or lower world, furnished with fields, meads, agreeable woods, groves, shades, rivers, &c., whither the souls of the virtuous were supposed to go after this life. Orpheus, Hercules, and Æneas, were said to have descended into Elysium in their life-time, and to have returned again, Virgil, lib. vi., v. 638. Virgil assigns Elysium to patriots who died for their country, to those of pure lives, to truly inspired poets, to the inventors of arts, and to all who have done good to mankind. Homer describes the Ἠλύσιον πέδιον, Odyssey, lib. iv.

> *Οὐ νιφετὸς οὔτ' ἀρ χειμὼν πολὺς οὔτε ποτ' ὄμβρος,*
> *Αλλ' αἰεὶ ζεφύροιο λιγυπνείοντος ἀήτας,*
> *Ωκεανὸς ἀνίησιν ἀναψύχειν ἀνθρώπης.*

Virgil introduces Anchises, saying,

> Exinde per amplum
> Mittimur Elysium, et pauci læta arva tenemus:
> Donec longa dies perfecto temporis orbe
> Concretam exemit labem, purumque reliquit
> Æthereum sensum, atque auraï simplicis ignem.
> Has omnes, ubi mille rotam volvêre per annos,
> Lethæum ad fluvium Deus evocat agmine magno:
> Scilicet immemores supera ut convexa revisant,
> Rursus et incipiant in corpora velle reverti.
> *Æneid*, lib. vi., v. 743.

The Elysian fields were, according to some, in the Fortunate Islands, on the coast of Africa. Others place them in the island of Leuce. Virgil says they were situated in Italy. According to Lucian, they were near the moon; or, in the centre of the earth, if we believe Plutarch.

ELZEVIRS (Lewis, Bonaventure, Abraham, Lewis, and Daniel), five celebrated printers at Amsterdam and Leyden, who, in the neatness and elegance of their small characters, greatly excelled all their predecessors. Their Virgil, Terence, and Greek Testament, have been reckoned their master-pieces; and, indeed, justly gained them the reputation of being the best printers in Europe. The first Lewis Elzevir began business at Leyden in 1590, and was remarkable for being the first who observed the distinction between the *v* consonant and *u* vowel, which had been recommended by Ramus and other writers long before, but never regarded. Daniel died in 1680 or 1681: and, though he left children who carried on the business, is esteemed the last of his family who excelled in it. He published the last of their typographical catalogues in seven parts.

EMA'CIATE, *v. a.* & *n.* & *adj.* } Lat. and
EMACIA'TION. } Ital. *emaciare; e*, and *maceo*, from Gr. *μακρος*, long; according to Vossius because bodies as they become lean, or lose their breadth, appear to increase their length. To deprive of flesh; to waste; to become meagre or lean: as an adjective, sunk; deprived of flesh: emaciation is the state of one grown lean.

Men after long *emaciating* diets wax plump, fat, and almost new. *Bacon.*

All dying of the consumption, die *emaciated* and lean. *Graunt's Bills of Mortality.*

Searchers cannot tell whether this *emaciati*[...] leanness were from a phthisis, or from a hectic f[...] *Gra*[...]

He *emaciated* and pined away in the too an[...] inquiry of the sea's reciprocation, although drowned therein. *Brou*[...]

To those who are past the meridian of life, [...] have dry skins, and begin to be *emaciated*, the w[...] bath, for half an hour, twice a week, I believe [...] eminently serviceable in retarding the advanc[...] age. *Darw*[...]

EMAC'ULATE, *v. a.* } Lat. *emaculo*, f[...]
EMACULA'TION, *n. s.* } *e*, privative, and *cula*, a stain or spot. To make clean; take spots or stains.

Others have taken great pains with him [Taci[...] in *emaculating* the text. *Hal*[...]

EM'ANATE, *v. n.* } Fr. *emaner*; Lat. *e*[...]
EM'ANANT, *adj.* } *nare*, from *e*, and *ma*[...]
EMANA'TION, *n. s.* } to run in a small strea[...]
EMANA'TIVE, *adj.* } To proceed or is[...]
EM'ANE, *v. n.* } from; emane has [...] same signification; emanant is issuing fr[...] something else.

The experience of those profitable and excell[...] *emanations* from God, may be, and commonly a[...] the first motive of our love. *Taylo*[...]

The first act of the divine nature, relating to [...] world, and his administration thereof, is an *emana*[...] act: the most wise counsel and purpose of Almigh[...] God terminate in those two great transient or *emana*[...] acts or works, the work of creation and providence. *Hale's Origin of Mankind*

It is against the nature of *emanative* efforts to su[...] sist but by the continual influence of their causes. *Glanville*

Another way of attraction is delivered by a tenuo[...] *emanation*, or continued effluvium, which, after som[...] distance, retracteth unto itself; as in syrups, oils, an[...] viscosities, which spun, at length retire into thei[...] former dimensions. *Browne.*

> Such were the features of her heavenly face;
> Her limbs were formed with such harmonious grace
> So faultless was the frame, as if the whole
> Had been an *emanation* of the soul. *Dryden.*

The actions, which naturally flow from such a well-formed mind, please us also, as the genuine marks of it; and being, as it were, natural *emanations* from the spirit and disposition within, cannot but be easy and unconstrained. *Locke.*

Swift, in his proposals for a Chamber of Fame, says, 'All news-writers are excluded, because they consider fame as it is a report which gives foundation to the filling up their rhapsodies, and not as it is the *emanation* or consequence of good and evil actions.' *Tatler.*

Aristotle said, that it streamed by connatural result and *emanation* from God, the infinite and eternal Mind, as the light issues from the Sun. *South.*

> Each *emanation* of his fires
> That beams on earth, each virtue he inspires;
> Each heart he prompts, each charm he can create;
> Whate'er he gives, are given for you to hate. *Pope.*

We may even seem to hear the Supreme Intelligence give this commission to the spirits which *emaned* from him. *Sir W. Jones.*

> But wisdom loves the calm and serious hour,
> When heaven's pure *emanation* beams confessed;
> Rage, ecstacy, alike disclaim her power,
> She wooes each gentler impulse of the breast.

EMAN'CIPATE, *v. a.* } Fr. *emanciper*;
EMANCIPA'TION, *n. s.* } Spanish, *emancipare*;
EMAN'CIPATOR. } Ital. and Lat. *emancipare*, from *e*, from, *manu*, the hand, and *capere*, to take. To take from the hand or power; to free from labor or servitude; to set at liberty; an emancipator is he who bestows freedom on another.

Having received the probable inducements of truth, we become *emancipated* from testimonial engagements. *Browne.*

Obstinacy in opinions holds the dogmatist in the chains of error, without hope of *emancipation*. *Glanville's Scepsis.*

By the twelve tables, only those were called unto the intestate succession of their parents that were in the parents' power, excluding all *emancipated* children. *Ayliffe's Parergon.*

They *emancipated* themselves from dependence. *Arbuthnot.*

By the former, he has *emancipated* property; by the latter, he has quieted conscience; and, by both, he has taught that grand lesson to government and subject—no longer to regard each other as adverse parties. *Burke.*

When a proposal is made to *emancipate* or relieve, you hesitate, you deliberate for years, you temporise and tamper with the minds of men; but a death-bill must be passed off hand, without a thought of the consequences. *Byron.*

Let us refute the sophisms of both, and first of the *emancipators*. *Merits of the Catholics, &c.*

EMANCIPATION, in the Roman law, the setting free a son from the subjection of his father; so that whatever moveables he acquired belonged as property to him, and not to his father, as before emancipation. Emancipation put the son in a capacity of managing his own affairs, and of marrying without his father's consent, though a minor. Emancipation differs from manumission, as the latter was the act of a master in favor of a slave; whereas the former was that of a father in favor of his son. There were two kinds of emancipation, viz.

EMANCIPATION, EXPRESS, where the father declared before a judge, that he emancipated his son. In performing this, the father was first to sell his son imaginarily to another, whom they called pater fiduciarius, father in trust; of whom being bought back again by the natural father, he manumitted him before the judge by a verbal declaration.

EMANCIPATION, TACIT, by the son's being promoted to some dignity, by his coming of age, or by his marrying, in all which cases he became his own master of course.

EMAS'CULATE, *v. a.* & *adj.* } Lat. *e*, and
EMASCULA'TION. } *masculus*, from *mas*, a male. To deprive of manhood or virility; hence, to deprive of strength or fortitude: as an adjective, emasculate signifies weakened, effeminate, unmanned.

Whence it is found how many ewes, suppose twenty, the ram will serve, we may geld nineteen, or thereabouts; for if you *emasculate* but ten, you shall, by promiscuous copulation, hinder the increase. *Graunt.*

From wars and from affairs of state abstain;
Women *emasculate* a monarch's reign. *Dryden.*

Dangerous principles impose upon our understandings, *emasculate* our spirits, and spoil our temper. *Collier.*

EMBABE, a small town of Egypt, opposite to Boulac, the port of Cairo. It produces excellent butter, and the fertile plains around enable it largely to supply Lower Egypt with a species of lupine. Near this place was fought, in 1798, the battle between Buonaparte and the Mamelukes, commonly called the Battle of the Pyramids, in which the former forced the latter to retire into Upper Egypt.

EMBALE', *v. a.* Fr. *emballer*; Germ. *emballen*. To make up in bales or parcels.

Below her arm her weed did somewhat train,
And her straight legs most bravely were *embaled*
In golden buskins of costly cordwain. *Faerie Queene.*

EMBALM', } Fr. *embaumer*; Span. and
EMBALM'ER. } Port. *embalsamar*; Ital. *imbalsamare*, from Lat. *balsamum*, balm, the principal ingredient used in preserving the dead among the ancients. Minsheu. See BALM. To impregnate with balm or aromatics; to preserve from destruction or putrefaction.

So Joseph died, and they *embalmed* him, and he was put in a coffin in Egypt. *Bible. Gen.* l. 26.

The Romans were not so good *embalmers* as the Egyptians, so the body was utterly consumed. *Bacon's Nat. Hist.*

I would show future times
What you were, and teach them t' urge towards such:
Verse *embalms* virtue, and tombs or thrones of rhymes
Preserve frail transitory fame as much
As spice doth bodies from corrupt air's touch. *Donne.*

Muse! at that name thy sacred sorrows shed;
Those tears eternal that *embalm* the dead. *Pope.*

Though time still wears us, and we must grow old,
Such men are not forgot as soon as cold,
Their fragrant memory will outlast their tomb,
*Embalmed* for ever in its own perfume. *Cowper.*

EMBALMING is the opening a dead body, and filling it with odoriferous and desiccative drugs and spices, to prevent its putrefying. The Egyptians excelled all other nations in the art of preserving bodies from corruption; for some, that they have embalmed upwards of 2000 years ago, remain entire to this day, and are brought into other countries as great curiosities. They are said to have drawn out the brains with an iron scoop at the nostrils, and to have thrown in medicaments to fill up the vacuum: they also took out the entrails, and having filled the body with myrrh, cassia, and other spices, except frankincense, proper to dry up the humors, they pickled it in nitre, in which it lay for seventy days. The body was then wrapped up in bandages of fine linen and gums, and was delivered to the kindred of the deceased, entire in all its features, the very hairs of the eye-lids being preserved. They used to keep the bodies of their ancestors, thus embalmed, in mausoleums magnificently adorned. The Egyptians also embalmed birds, &c. The prices for embalming were different: the highest was a talent, the next twenty-nine minæ; but those who could not afford this expense, contented themselves with infusing, by means of a syringe, a liquor extracted from the

cedar, and wrapping up the body in salt of nitre; the oil thus preyed upon the intestines, so that when they took it out, the intestines came away with it, dried, and not in the least putrefied; the body being enclosed in nitre, grew dry, and nothing remained besides the skin glued upon the bones. The modern Egyptians are said to wash the body several times with rose-water, and afterwards to perfume it with incense, aloes, and other odors, of which they are by no means sparing; they then bury it in a winding-sheet, made partly of silk and partly of cotton, and moistened with some sweet-scented water or perfume. This they cover with another cloth of unmixed cotton, to which they add one of the richest suits of clothes of the deceased. See MUMMY.

EMBANKMENT, in civil engineering, is a mound, dam, or wall of earth, or other materials applied to the direction or protection of water courses, or the preservation of land from the encroachments of the sea. It may also form the boundary of a dock or reservoir, and be the foundation of roads or railways.

The history of the earliest civilised state in the world, Egypt, must have taught mankind at a very remote period the value of alluvial deposits; and hence the importance of some species of embankment. The whole of that country, we know, is divisible into absolute deserts, and a soil rendered highly fertile from this source. Babylon was in the same situation with regard to the character of her fertile soil. It was a saponaceous clay irrigated by the waters of the Euphrates: a causeway leading over these low grounds to her celebrated bridge, is one of the most famous embankments upon record. All the early civilised nations indeed seem to have chosen alluvial plains and valleys as their favorite residences—'plains well watered every where,' as the Scripture so well expresses it: and where the soil by its mingled warmth and moisture should more quickly and amply repay their rude toil.

The Greeks, inhabiting a rocky and hilly country, interspersed with rich vales, but having a soil generally light and sandy, or a calcareous subsoil, had little occasion for embankments of any kind, and have left therefore but few traces of the art of constructing them. According to Potter, lands were enclosed with a ring-fence, or boundary mark; but most of the country was open pasture. Solon regulates the depth of water, and decrees that 'he who digs a ditch, or makes a trench nigh another's land, shall leave so much distance from his neighbour as the ditch or trench is deep.'

The Romans were the first scientific agriculturalists; their greatest men in the camp and in the city, and some of their most able writers, we know devoted themselves to this science. Of the surface of Italy the immense valley of the Po and the marshy plain of Terracino constitute capital features; and the embankments on the former as well as those on the Tiber, of many stadia in length, are striking memorials of the Roman art of embanking. Cato gives directions for opening the furrows of sown fields, and clearing them so as the water might find its way readily to the ditches; and for wet-bottomed lands he directs to make drains three feet broad at top, four feet deep, and one foot and a quarter wide at the bottom; to lay them with stones; or, if these cannot be got, with willow rods, placed contrary ways, or twigs tied together (Cap. 43). Columella directs both open and covered drains to be made sloping at the sides, and in addition to what Cato says respecting the water way of covered drains, directs to make the bottom narrow, and fit a rope made of twigs to it, pressing the rope firmly down, and putting some leaves, or pine branches over it, before throwing in the earth. Pliny says, the ropes may be made of straw, and that flint or gravel may be used to form the water-way, filling the excavation half full, or to within eighteen inches of the top.

To advert again for a moment to the east, where, if agriculture has been pursued with very little science, the importance of irrigation is at least well known and appreciated, Dr. Davy, in his account of the interior of Ceylon, describes an artificial mound or embankment, forming the lake or tank of Kandellé, which seems to rival the most celebrated works of this kind in history. This lake, wholly of artificial construction, is from three to four miles in circumference, and, like that of Minere, says he, skirted with green plains.

'The embankment by which the water is confined is a mile and one-third long. It extends nearly in a straight line, from a rocky hillock at one extremity, to a high ledge of rock at the other. Its perpendicular height may be about twenty feet; at its base it may be 150, or 200 feet, wide. Its face towards the lake is naked, sloped at an angle of about 45°, and composed of stones that rise one above the other like steps. The stones are of the same size nearly; from two to three feet long, about two high, and from one to two wide. They are of the same kind as the adjoining rock. It is, perhaps, worth remarking, that they have no sharp angles or asperities of surface; they have the appearance of quarried stones, rendered thus smooth by the action of the elements in long process of time. On the land-side the slope is very gentle, and the embankment is of gravel and earth. The stone face of the embankment is shaded by trees of great size; the other side is covered with large forest-trees and thick underwood, in most places impenetrable. Besides the great embankment, there is a small one detached from it about a quarter of a mile, and nearly at right angles to it, similarly constructed.

'The great outlet or sluice is constructed with much art and of vast strength; the channel is beneath a platform of masonry that projects into the lake about six feet beyond the line of the embankment, and is about twenty-four feet long. It is built of oblong stones, from five to seven feet long, well wrought and nicely adapted to each other without cement. The top of the platform is flat; it contains a small cylindrical well, communicating directly with the channel below, and in which the water, in passing, rises of course to the level of the lake.' The water, passing through the embankment, appears on the other side gushing out in a noble stream through two apertures

formed by a transverse mass of rock supported by three perpendicular masses. The transverse mass, which is now cracked in two, is about twelve or fourteen feet long, and four or five thick; and the other masses are of proportional size. The water rushing out in a considerable volume with great force, dashing amongst rocks beneath, in a deep gloomy shade produced by overhanging trees, makes altogether a very striking scene. The work itself has a simple grandeur about it which is seldom associated with art; it looks more like a natural phenomenon than the design of man.'

Agriculture was introduced by the Romans into every conquered province, and practised by the soldiers of their armies wherever they were stationary. Cæsar speaks of its being introduced into this country by colonies from Belgium, who cultivated the sea-coasts (about B.C. 150), while the natives were driven into the interior. Be this as it may, we have numerous traces of the embankments of Roman agriculture; and to that people is doubtless owing the general diffusion of the art in Britain. They perhaps first confined the channel of the Thames; and the embankments of Romney Marsh in Kent, as well as several noble mounds in the fenny part of Cambridgeshire, have been attributed to them.

But Holland and Flanders exhibit a scene of noble triumphs arising from this art. The embanked lands are here called polders, and consist of various areas reclaimed from the sea; the surface of which, once secured from the tide, becomes the most productive of earthy soils without any manure. The newly formed lands, before this embankment, are called schorres. They are flooded at every tide by the water of the sea, and are augmented by mire, pieces of wood, rushes, sea-weeds and other marine plants decayed and putrid, also by shells and fishy particles which the ebb always leaves behind in considerable quantity. This growing soil soon produces various plants and grasses, and improves daily. When such lands have acquired a crust or surface of black earth, three or four inches deep, they may be embanked and fallowed. Those are the most productive which have been deepened in their soil by the augmentations of the sea; and experience proves that, in the corners and hollows, where, from an obstructing boundary, the greatest quantity of mire has been deposited, the soil is doubly rich and good, and cannot be impoverished by the crops of many years. In some instances the embankments are made on the part of government, in others by companies or individuals, under a grant of a specific tenure (generally twenty-one years), rent free, or according to circumstances, at some moderate annual payment. The polder of Snaerkskirke, near Ostend, contains about 1300 acres. It is of late formation, and was overflowed by a creek with its minor branches every spring tide. By constructing two banks and a flood-gate, at the creek, the sea is excluded and the space subdivided by roads and laid out in fields, of thirteen acres each, surrounded by ditches. The bank is fifteen feet in height, thirty feet in the base, and ten feet across the top: the land which has been reclaimed by it was let for a sheep pasturage at 600 francs (£25) per annum, and was thrown up by the farmer as untenable. Upon being dried by this summary improvement, the lots of which are 100, of thirteen acres each, and were sold by auction at an average of 7000 francs (£291. 13*s*. 4*d*.), each would now bring nearly double that rate.

Another polder, called the Great Moor, recovered through the spirited exertions of M. Hyrwein, contains 2400 acres. Attempts had been made to recover it by the Spaniards in 1610, but without success. This marsh was seven feet below the level of the surrounding land; to drain it, therefore, it became necessary to surround the whole with a bank of eight feet in height, above the level of the enclosed ground, formed by the excavation of a fossée, fifteen feet wide and ten feet deep, which serves to conduct the water to the navigable canal;—to construct mills to throw the water over the bank into the fossée; and to intersect the interior by numerous drains, from eight to twelve feet wide, with a fall to the respective mills, to which they conduct all the rain water, and all the soakage water which oozes through the banks.

In North and South America embankments have been attempted in the neighbourhood of all the principal rivers as fast as settlers have accumulated; and some of the most interesting in the world are those of the Mississippi, extending from near its mouth at Balize, several hundred miles up the country; and protecting a most fruitful soil for sugar-canes.

The true mathematical principles of all these erections has been thus well stated by a contemporary:—'The pressure of still water against the sides of the vessel containing it being as its depth, it follows, that a bank of any material whatever, impervious to water, whose section is a right angled triangle, and the height of whose perpendicular side is equal to that of the water it is to dam in, will balance or resist this water, whatever may be the breadth of the surface of the latter; and, therefore, that as far as width or extent is concerned, it is just as easy to exclude the Atlantic Ocean as a lake or a river of a few yards in width.'

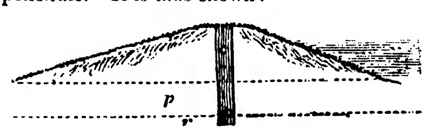
The modern embanking system of England, though at first, and when he was a private gentleman, discouraged as we have seen by CROMWELL (vide that article), was first patronised by him, afterwards as protector of the commonwealth: during which 425,000 acres of fen land were recovered in Lincolnshire, Cambridgeshire, and Kent, by colonel Vermuyden a Fleming, and an officer who had served immediately under the protector. The oldest embankment in England is unquestionably that of Romney Marsh, as to the construction of which, Dugdale remarks: 'that there is no testimony left to us from any record or historian.'

Embankments from the sea; from an inlet or bay of water; from the course of rivers; and from the floods common in fenny districts; are all clearly distinct operations. For the first, the earthen mound is in most general use and applies both to sea lands overflowed by every spring tide, and to alluvial plains inundated by every flood It is generally set out

in a direction parallel to the shore, or to the general turns of a river, but not to its minute windings: and it is placed farther from or nearer to the latter, according to the quantity of water in time of floods, the rapidity of the current from the declivity of the bed, the straight course of the stream, and the intended height of the bank. The two sides of such a mound are generally formed in different slopes. That towards the land is always the most abrupt, but can never be secure if more so than 45°; that towards the water varies from 45° to 15°; the power of the bank to resist the weight of the water, as well as to break its force when in motion, being inversely as its steepness. The power of water to lessen the gravity of bodies, or in other words, to loosen the surfaces over which they flow or stand, is also lessened in a similar ratio. The mound is thus exhibited:—

The construction of this embankment is very simple, and consists ordinarily of taking the earth by barrows or carts on rollers from the general surface to be protected, or from a collateral excavation, distant at least the width of the mound from its base line, and heaping it up in the proper form. The surface is then protected with turf, well rolled in order to bind it. When an excavation is made it serves the same purposes as an open drain in the earthen wall hereafter described; and similarly constructed sluices or valves are introduced on a larger scale. Sometimes also the interior water is drawn off by wind-mills, and thrown over the mound into the river. This is very common both in Cambridgeshire and Huntingdonshire, and might be greatly improved on by employing steam-engines for entire districts. Nature herself seems to dictate the mode imitated in Holland for preserving the upper part of their embankments. After the tides of the Po have left a mere strip of sand, it becomes quickly covered with vegetation in which the elymus arenarius, triticum junceum, and various species of juncus are conspicuous. As these and the debris of shells with which they are mingled decay, the fibrous roots of good grass flourish and soon occupy their place. The wicker-work embankments of Holland, studded with brush-wood, are clearly but an improvement upon this. The forming a bank of branches filled with sand and shells has also been suggested; and regularly constructed of frame timber, the section of which would resemble a trussed roof: each truss being joined in the direction of the bank of rafters, and the whole inside and surface stuck full by branches. To retain it firm, piles would require to be driven into the sand, to the upper parts of which would be attached the trusses. The height of such a barrier would require to be several feet above that of the highest spring-tides; and the more its width at base exceeded the proportion of that of an equilateral triangle the better. A more economical mode, and one, therefore, suited to a less extensive scale of operation, is to intersect a sandy shore in all directions, with common dead, or wicker-work hedges, formed by first driving a row of stakes six or eight feet into the ground, leaving their tops three or four feet above it, and then weaving among these stakes branches of trees, or the tops of hedges. *Encyclopædia Britannica, Supplement.*

Embankments of the above kind are the most common of any; they appear on all parts of the continent, and the eastern shore of England, richly covered with grass and often with trees. Their sections vary from a scalene triangle of ten feet in base, and three feet in height, as on the Forth near Stirling, and the Thames at Fulham, to a base of 100 feet, and a height of ten feet, as in the great bank near Wisbeach. Many of the great rivers of Germany and Holland are embanked in this way, when so far from the sea as to be out of the reach of the tide; as the Vistula at Marienwerder, the banks of which, near Dantzic, are above fifteen feet in height; the Oder, the Elbe, &c. Sometimes the earthen mound is assisted by the previous construction of a puddle ditch or clay wall of about four or five feet wide, in the centre of its highest part, and in the direction of its length. When this is well worked no water will penetrate it; and it may save the accumulation of materials in the bank itself. A great object here is to dig this ditch sufficiently deep to penetrate through the porous stratum, and come in contact with an argillaceous soil, or that which water will not penetrate. It is thus shown:—



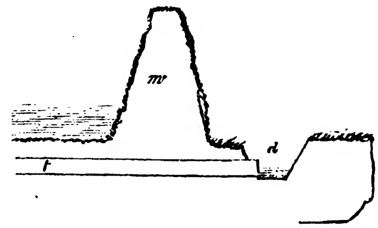
Here *c* is the clay wall, *p* the porous, and *r* the retentive, stratum. In particular situations, where it is an object to conceal the slope from the eye, the steepest part is placed next the water, as above; but this is certainly the weakest mode of protecting the land: by the difference of the weight of the triangle of water which would rest on the longer in comparison with that which rests on the shorter slope. A slope next the water of 45° or 50° is sometimes paved or causewayed with stones or timber. In Holland this pavement is often formed of planking or bricks; but in England generally with stones, and the mortar used is either cement which will set under water, or plants of moss firmly rammed between them. The objection to such banks is their expense, and their liability to be undermined invisibly by the admission of the water through crevices.

The concave *sea-wall* is a protected embankment formed against abrupt and earthy shores, and consists of a wall, varying in thickness, and the inclination of its surface, according to circumstances. M. Belidor, in his Traité de Hydraulique, professes to give the exact curve which the section of such a wall ought to have, in order to resist loose earth, and which is somewhat greater than where the earth behind the wall is supposed to be chiefly firm. Examples of such

walls occur in the Caledonian Canal; but the finest in the world are said to be those of granite which embank the Neva at St. Petersburgh.

One of the noblest attempts at a sea embankment in this, or perhaps any other country, was that commenced by W. A. Madocks, Esq. M. P., in 1807, to unite the counties of Merioneth and Cardigan by a mound across an estuary and embouchure of the Glasslyn. In 1802 this gentleman had constructed a wall or bank, by which he recovered 1800 acres of good alluvial soil from spring tides, and let them at from 30*s.* to 50*s.* per acre. He now contemplated the idea of gaining the whole bay or mouth of the stream, here two miles wide; extending to nearly 4000 acres of alluvial and sandy earth; and uniting, as we have said, the two counties. This would have rendered practicable a new line of road from Worcester along the top of his embankment, through the town of Tre Madoc, to the newly-formed harbour of Porthdynlleyn; by which forty miles of road would have been saved between Dublin and London, and fifty between Dublin and Bath. His first operation consisted in forming an immense bridge of floodgates in the solid rock of the shore, to admit the exit of the river; when the mound was commenced from both shores. The greater part of its materials were argillaceous rock broken into small pieces, mixed with clay and thrown down so as to take their own slope. An iron rail-way was formed along the work as it extended and led to the quarries and excavations. After three years' exertion the work was brought within fifty yards of meeting in the middle, but the rapidity of the influx and reflux of the tide here made the progress to its completion very difficult. To this, unfortunately, was now added pecuniary difficulties, which closed the undertaking, when it was calculated that £20,000 would have finished it. Sir Hugh Middleton, it is said, entertained a similar project as to this part of the country.

The *earthen-wall* of various inland districts is also to be considered as a species of embankment, although often erected by temporary occupiers of lands for the mere purpose of enclosing and subdividing them. It best applies to lands occasionally, but rarely overflown, or inundated; and is set out in a direction parallel to the river or shore. It is generally commenced from four to five feet wide, and built of turf with the grass side inwards, the middle being filled with earth; and finishing in about a foot or eighteen inches breadth at top, and at about five or six feet in height. As a collateral drainage inside such wall, and at the distance of three or four feet, a small open ditch is formed, out of which the water is let through the wall by tubes, or tunnels of boards, with a valve opening on their exterior extremity. When the flow of water from without approaches, it shuts the valve, which remains in this state till the flood subsides; when, the height of the water within being greater than that without, it opens the valve and flows off. These are common enough in the drier parts of the fenny districts of Lincolnshire and Cambridgeshire; and in Caernarvonshire 1800 acres were, in 1804, completely protected in this way on the estate of Tre Madoc already mentioned.



Here *w* is the wall, *d* the inner open drain, and *t* the tube or wooden tunnel through which its redundant waters are carried off.

*River* embankments are formed for protecting the existing course of their waters; for changing or accommodating that course to particular circumstances, and sometimes for altering or diverting it altogether.

Piers or guards are common modes of protecting the opposite bank when, in a crooked stream, or from some other cause, an obstacle accumulates. Mr. Marshall has discussed the proper kind of defences to be adopted in this case, in his Treatise on Landed Property: but they are to be used with great caution, and are only to be justified where the obstruction itself cannot, as Smeaton recommends it should, be removed from the opposite bank; or where, as is sometimes the case, it arises from an island of sand or gravel thrown out by the river near its middle, and which the interested parties perhaps cannot agree to remove. The case of buildings also being in danger may justify such a pier for immediate protection: if such breaches, however, are taken in time, a few loads of loose stones will generally effect a better remedy.

In forming a permanent land-guard of this kind, Mr. Marshall recommends, that the foundation be laid pretty deep, to guard against any accidental scoopings. The wall ought to be carried up dry, or without mortar, the stones being laid with their ends outward, their inner ends pointing to the same centre, like those of an arch, and to be backed with gravel or earth, rammed in firmly behind, as the facing is carried up. The coping or uppermost course of the stones is to be securely bound with thick tough sods, eight or ten inches deep, whose surfaces, when beaten down ought to lie even with that of the stone-work; and similar sods require to be laid, with a gently rising slope, until they unite smoothly with the natural turf of the land to be defended; so that the waters of floods, when they rise above the stone-work, may have no abruptness to lay hold of, but may pass away smoothly over the surface of the land, as they commonly do over smooth greensward, without injury. Finally, the stones are to be beaten forcibly into the bank, with a rammer, a mallet, or a small battering-ram, adapted to the purpose; thus rendering the whole compact and firm, to resist the current. Where vacancies or fissures still appear, long splinters of stone are to be driven in, as wedges, to increase the firmness, and prevent the current from tearing out an unguarded stone. It follows, in course, that the largest and longest of the stones ought to be used

where the greatest resistance is known to be required.

The sheath, or land-guard of loose stones, which this author also recommends, and which is the mode already mentioned as approved by Smeaton, is applicable where the river is confined in the part where it is required to be bent, by rocks or otherwise, to an unaltered channel; as it frequently is, in subalpine situations; as also where a deep pool occurs, in that part, in low water, so as to render it difficult to get a proper foundation for a pier. Where the foot of the injured bank is covered with a pool at low water, shelve off the brink of the bank, and shoot down loose stones from the top of it; suffering them to form their own slope, in the action of falling, and by the operation of succeeding floods, continuing to pour them down until the bank be secured, at least from minor floods, and then slope back the upper part, to give freedom to floods of higher magnitude.

Where, in flat countries, and surrounded by a valuable soil, a river is very circuitous, and much land may be gained or protected by a more rapid efflux of the water, its course must be either straightened or abandoned. The best plan in general is to find an entirely new bed or course for the river; otherwise, when it passes alternately through new soil, and through a part of its old bed, its action on surfaces which are so different in regard to induration ends, if great care is not taken, in holes and gulleys in the new bank, which require to be constantly filled up and repaired. The embankment used in straightening the course of rivers is always the mound, with a clay wall in the centre, varying in width according to the depth of the different parts of the old bed which it has to intersect, and the materials are obtained from excavations.

The hundred feet drain and other great outlets of the Bedford Level have been all constructed on the principle of straightening the water courses; which the late Mr. Rennie is said to have proposed to carry to a still greater extention in that district. One beautiful triumph of art in this neighbourhood, has at length been completed in the Eau Brink Cut, an entirely new outlet for the ancient Ouse. The bed of the old river was abandoned about five years ago, and it now presents the singular sight of being silted up, for nearly eight miles together, higher than the level of the adjacent lands. Tufts of vegetables appear all along, and in a few years, together with the whole neighbouring country being rescued from floods, this site will yield valuable cultivable soil.

Embankments that are designed to serve as the foundation of rivers are generally mounds without the clay section we have described.* The earth, in such cases, is allowed to take its own slope on both sides, which is commonly from 40° to 45°, and the width at top is regulated by that of the intended road or rail-way. The materials are excavated from ditches, or yielded by the adjacent surface on each side. In Holland such roads are generally bounded by trees which form an excellent guide at night to the eye of the traveller in flat countries. The first operation, where it can be accomplished, is to lay a foundation, three or four feet thick, of branches or faggots of copsewood, in order that the mound may sink in a body. Then, the direction of the mound being marked out by a line of poles, the barrowing or carting of the earth is carried on from end to end, until it reaches the proper height and width; leaving the slopes at the sides to form themselves, or assisting them by puddling them with water. See Engineering

EMBA'R, *v. a.* From em and bar. To shut; to enclose.

> Themselves for fear into his jaws to fall,
> He forced to castle strong to take their flight;
> Where fast *embarred* in mighty brazen wall,
> He has them now four years besieged to make them thrall. *Spenser.*
>
> Translating the mart unto Calais, he *embarred* all further trade for the future. *Bacon's Henry VII.*
>
> If this commerce betwixt heaven and earth were not
> *Embarred*, and all this traffic quite forgot,
> She, for whose loss we have lamented thus,
> Would work more fully and powerfully on us. *Donne.*
>
> In form of airy members fair *embarred*,
> His spirits pure were subject to our sight. *Fairfax.*

EMBA'RGO, *n. s.* Span. *embargar.* A prohibition to pass; in commerce, a stop put to trade.

> He knew that the subjects of Flanders drew so great commodity from the trade of England, as by *embargo* they would soon wax weary of Perkin. *Bacon's Henry VII.*
>
> After an *embargo* of our trading ships in the river of Bourdeaux, and other points of sovereign affront, there did succeed the action of Rheez. *Wotton.*
>
> Wit is its own remedy. Liberty and commerce bring it to its true standard. The only danger is the laying an *embargo*. The same thing happens here as in the case of trade; impositions and restrictions reduce it to a low ebb; for nothing is so advantageous to it as a free port. *Shaftesbury.*
>
> I was not much concerned, in my own particular, for the *embargo* which was laid upon it. *Dryden.*
>
> This is a very delicate subject for gentlemen to speak on; it lays an *embargo* on the house. No man can put himself into the ungracious state of opposing the repeal of afflicting taxes. Who can deny to the poor family the boon of getting their candles cheap? *Sheridan.*

*An* Embargo is an arrest on ships or merchandise, by public authority; or a prohibition of state, commonly on foreign ships, in time of war, to prevent their going out of port, sometimes to prevent their coming in, and sometimes both for a limited time. The king may lay embargoes on ships, or employ those of his subjects, in time of danger, for the service and defence of the nation; but they must not be for the private advantage of a particular trader or company; and, therefore, a warrant to stay a single ship is no legal embargo. No inference can be made from embargoes which are only in time of war, and are a prohibition by advice of council, and not at prosecution of parties. If goods be laden on board, and after an embargo or restraint from the prince or state comes forth, and then the master of the ship breaks ground, or endeavours to sail, if any damage accrues he must be re-

sponsible for the same; the reason is, because his freight is due, and must be paid, even though the goods be seized as contraband.

EMBARK', *v. a.* & *n.* } Fr. *embarquer*; EMBARKA'TION. } Span. *embarcarse*, from *em*, i. e. *in* and *barca*, a small vessel.—Minsheu. To put or go on shipboard: and hence, to engage, or engage another in any affair.

The king had provided a good fleet, and had caused a body of 3000 foot to be *embarked* on those ships. *Clarendon.*

The French gentlemen were very solicitous for the *embarcation* of the army, and for the departure of the fleet. *Id.*

Of mankind, so numerous late,
All left, in one small bottom swam *embarked.*
*Milton.*

Straight to the ships Æneas took his way,
*Embarked* his men, and skimmed along the sea.
*Dryden's Æneid.*

I should with speed *embark*,
And with their embassy return to Greece.
*A. Phillips.*

*Embarked* in death, thy passage will be dark; and the shore, on which it will land thee, altogether strange and unknown. *Mason.*

But to our tale: the Donna Inez sent
Her son to Cadiz only to *embark*;
To stay there had not answered her intent.
*Byron.*

EMBAR'RASS, *v. a.* } Fr. *embarasser*, EMBAR'RASSMENT, *n. s.* } one of the compounds of bar, to stop. See BAR. To perplex; entangle; retard: hence, to distress.

I saw my friend a little *embarrassed*, and turned away. *Spectator.*

But here a mean
Observe, nor the large hound prefer, of size
Gigantic, he in the thick-woven covert
Painfully tugs, or in the thorny brake
Torn and *embarrassed* bleeds. *Somerville.*

Let your method be plain, that your hearers may run through it without *embarrassment*, and take a clear view of the whole. *Watts's Logick.*

To *embarrass* justice by a multiplicity of laws, or to hazard it by confidence in our judges, are, I grant, the opposite rocks on which legislative wisdom has ever split. *Goldsmith.*

Charles endeavoured to break this, and to *embarrass* Henry by another inroad of the Scots.
*Robertson. History of Scotland.*

And merely tend to show how greatly Love is
*Embarrassed* at first starting with a novice. *Byron.*

EM'BASE, *v. a.* From em and base. To make base; vitiate; depauperate; lower; impair.

Joy of my life, full oft for loving you
I bless my lot, that was so lucky placed;
But then the more your own mishap I rue,
That are so much by so mean love *embased.*
*Spenser.*

Clear and round dealing is the honour of man's nature, and mixture of falsehood is like alloy in coin of gold and silver, which may make the metal work the better, but it *embaseth* it: for these winding and crooked courses are the goings of the serpent; which goeth basely upon the belly and not upon the feet.
*Lord Bacon.*

I have no service or ignoble end, in my present labour, which may, on either side, restrain or *embase* the freedom of my poor judgment. *Wotton.*

I will rather chuse to wear a crown of thorns, than to exchange that of gold for one of lead, whose *embased* flexibleness shall be forced to bend.
*King Charles.*

A pleasure high, rational, and angelical; a pleasure *embased* with no appendent sting; but such a one as being honey in the mouth, never turns to gall or gravel in the belly. *South.*

EMBASS'ADOR, } See AMBASSADOR. Old EMBASS'ADRESS, } Fr. *embassadeur*. One sent EM'BASSAGE, } on a national or public EM'BASSY. } errand: hence any dignified or important messenger. The custom of our language is to write embassage and embassy, for the message, business, or commission; ambassador, or ambassadress, for the parties sent.

Fresh *embassy* and suits,
Nor from the state nor private friends, hereafter,
Will I lend ear to. *Shakspeare. Coriolanus.*

Nimble mischance, that art so light of foot,
Doth not thy *embassage* belong to me;
And am I last that know it? *Id. Richard III.*

When he was at Newcastle he sent a solemn *embassage* unto James king of Scotland, to treat and conclude a peace with him. *Bacon's Henry VII.*

Was it not for your sakes that he (Moses) thrust himself into the midst of that smoke and fire, which ye feared to see afar off? Was he not now gone, after so many sudden *embassages*, to be your leaguer with God? *Bp. Hall. Contemplations.*

He sends the angels on *embassies* with his decrees.
*Taylor.*

Mighty Jove's *embassador* appeared
With the same message. *Denham.*
Myself, my king's *embassador* will go. *Dryden.*
The peace polluted thus, a chosen band
He first commissions to the Latian land,
In threatening *embassy.* *Id. Æneid.*

A bird was made fly with such art to carry a written *embassage* among the ladies, that one might say, If a live bird, how taught? If dead, how made?
*Sidney.*

With fear the modest matron lifts her eyes,
And to the bright *embassadress* replies.
*Garth's Ovid.*

Nothing can be said to display the imperious arrogance of a base enemy, which does not describe with equal force and equal truth the contemptible figure of an abject *embassy* to that imperious power.
*Burke.*

EMBA'TTLE, *v. a.* & *n.* From battle. To range or be ranged in order or array of battle.

The English are *embattled*:
To horse! you gallant princes, strait to horse!
*Shakspeare.*

I could drive her from the ward of her reputation, her marriage-vow, and a thousand other her defences, which now are too strongly *embattled* against me.
*Id.*

The night
Is shiny, and they say we shall *embattle*
By the second hour of the morn. *Id.*
On their *embattled* ranks the waves return,
And overwhelm the war! *Milton's Paradise Lost.*
The prince who leads *embattled* thousands forth,
And with a nod commands the universe,
Knows not the language to make thee obey. *Howard.*
*Embattled* nations strive in vain
The hero's glory to restrain:
Streams armed with rocks, and mountains red with fire,
In vain against his force conspire. *Prior.*

A band undaunted, and inured to toils
Shall compass thee around, die at thy feet,
Or hew thy passage thro' the *embattled* foe,
And clear thy way to fame. *Somervile.*

They are gone,
Gone with the refluent wave into the deep—
A prince with half his people! Ancient towers,
And roofs *embattled* high, the gloomy scenes,
Where beauty oft and lettered worth consume
Life in the unproductive shades of death,
Fall prone. *Cowper.*

And, 'midst the horrors shrined of midnight storm
The fiend Oblivion eyes thee from afar,
Black with intolerable frowns her form,
Beckoning the *embattled* whirlwinds into war. *Beattie.*

EM'BAY, *v. a.* From *baigner* to bathe, Fr. To bathe; wet; or wash. Not used.

In her lap a little babe did play
His cruel sport;
For in her streaming blood he did *embay*
His little hands, and tender joints embrew. *Faerie Queene.*

Every sense the humour sweet *embay'd*,
And, slumbering soft, my heart did steal away. *Id.*

From *bay.* To inclose in a bay; to land-lock.

If that the Turkish fleet
Be not insheltered and *embayed*, they're drowned. *Shakspeare.*

EMBDEN, a considerable sea-port and fortified town of the kingdom of Hanover, situated on the river Embs or Ems, at its influx into the North Sea. It was long subject to Prussia; and, having a spacious harbour, has often been the object of patronage in regard to its trade. It was created a free port in 1751, and an East India trading company was established in 1769, but it did not flourish. Great benefit accrued to Embden, during the wars of the French revolution, from the neutrality of its flag. The harbour admits, at high water, vessels of thirteen feet of draught; and the roadstead offers a safe anchorage for the largest ships of war, little more than a mile from the town. Ship-building is carried on here; and a considerable export of oats, barley, butter, and cheese. The inhabitants are in general Calvinists. A canal is cut to Aurich, situated twelve miles to the south-west.

EMBEL'LISH, *v. a.* } Fr. *embellir*, from
EMBEL'LISHER, *n. s.* } Lat. *bellus*, fine, hand-
EMBEL'LISHMENT. } some. To adorn, beautify, or ornament. Embellishment is often used sarcastically for exaggeration or falsehood. See the extract from Atterbury.

How much more beauteous had the fountain been,
*Embellished* with her first created green;
Where crystal streams through living turf had run,
Contented with an urn of native stone. *Dryden's Juvenal.*

The names of the figures that *embellished* the discourses of those that understood the art of speaking, are not the art and skill of speaking well. *Locke.*

That which was once the most beautiful spot of Italy, covered with palaces, *embellished* by emperors, and celebrated by poets, has now nothing to shew but ruins. *Addison on Italy.*

Cultivate the wild licentious savage
With wisdom, discipline, and liberal arts,
The *embellishments* of life. *Id. Cato.*

Apparitions, visions, and intercourses of all kinds between the dead and the living, are the frequent and familiar *embellishments* of the legends of the Romish church. *Atterbury.*

Painting and sculpture are express imitations of visible objects; and where would be the charms of poetry, if divested of the imagery and *embellishments* which she borrows from rural scenes? *Percival.*

And as for you, my lady Squeamish,
Who reckon every touch a blemish,
If all the plants that can be found
*Embellishing* the scene around
Should droop and wither where they grow,
You would not feel at all—not you. *Cowper.*

EMBERIZA, in ornithology, a genus of birds belonging to the order of passeres. The bill is conical, and the mandibles recede from each other towards the base; the inferior mandible has the sides narrowed inwards; the upper one has a hard knob within. Species about seventy-seven. The most remarkable are:—

1. E. citrinella, the yellow-hammer, with a blackish tail, the two outward side-feathers marked on the inner edge with a sharp white spot. It is a bird of Europe, and visits the houses in winter; it builds its nest on the ground on meadows.

2. E. hortulana, the ortolan, has black wings; the first three feathers on the tail are white on the edges, the two lateral are black outwardly. The orbits are naked and yellow towards the inferior mandible. It feeds principally upon the panick grass; grows very fat; and is reckoned a great delicacy by epicures. These birds are found in several parts of Europe. In some parts it makes the nest in a low hedge; in others on the ground. The female lays four or five grayish eggs, and in general has two broods in a year. To fatten these birds for the table, they are placed in a chamber lightened by lanterns; where, not knowing the vicissitudes of day and night, they are constantly fed with oats and millet; and grow so fat, that they would certainly die if not killed in a critical minute. They are a mere lump of fat; of a most exquisite taste, but soon apt to satiate.

3. E. miliaris, the gray emberiza, is of a grayish color, spotted with black in the belly, and the orbits are reddish. It is the bunting of English authors, and a bird of Europe.

4. E. nivalis, the great pyed mountain finch of Ray, and the snow bird of Edwards, has white wings, but the outer edge of the prime feathers are black; the tail is black, with three white feathers on each side. These birds are called in Scotland snow-flakes, from their appearance in hard weather and in deep snows. They arrive in that season among the Cheviot hills, and in the Highlands, in large flocks. They appear in the Shetland islands; then in the Orkneys; and multitudes of them often fall, wearied with their flight, on vessels in the Pentland Frith. Their appearance is a certain fore-runner of hard weather, and storms of snow, being driven by the cold from their common retreats. They visit at that season all parts of the northern hemisphere, Prussia, Austria, and Siberia. They arrive very poor and return fat. In Austria they are caught and fed with millet, and, like the ortolan, grow excessively fat.

5. E. oryzivora, or the rice bunting, with the head and whole under side of the body black; hind part of the neck in some pale yellow, and in others white; coverts of the wings and primaries black, the last edged with white; part of the scapulars, lesser coverts of the wings, and rump white; back black, edged with dull yellow; tail of the same colors, and each feather sharply pointed; the legs are red. The head, upper part of the neck, and back, of the female, is yellowish-brown, spotted with black; the under part of a dull yellow; the sides thinly streaked with black. These birds are very numerous in the island of Cuba, where they commit great ravages among the early crops of rice, which precede those of Carolina. As soon as the crops of that province are more advanced, they quit Cuba, and pass over the sea in numerous flights, and appear in Carolina in September, while the rice is yet milky. Here they commit such devastations, that forty acres of that grain have been totally ruined by them in a short time. They arrive very lean, but soon grow so fat as to fly with difficulty. They continue in Carolina not much above three weeks, and retire when the rice begins to harden. They come into Rhode Island and New York in the end of April, or the second week in May, frequenting the borders of fields, and living on insects, &c., till the maize is ready, when they peck holes in the sides of the husks, which leaves room for the rain to get in, and effectually spoils the plants. They continue there during the summer, and breed; returning, as autumn approaches, to the southward. The males and females do not arrive together; the females come first. They are esteemed the most delicate birds of those parts; and the male is said to have a fine note.

6. E. schoeniclus, the reed sparrow, has a black head, a blackish-gray body, and a white spot on the quill-feathers. It inhabits marshy places most commonly among reeds. Its nest is very artificially contrived, being fastened to four reeds, and suspended by them like a hammock, more than three feet above the water; the cavity of the nest is deep but narrow; and the materials are bushes, fine bents and hairs. It lays four or five eggs of a bluish-white, marked with irregular purplish veins, especially on the larger end. It is a bird much admired for its song; and sings most in the night.

EM'BERS, *n. s. plur.* Sax. æmyrja; Goth. *emmyria*; Isl. *einmyria*; Swed. *askmeria*; Teut. *ammer*, from Sax. el, fire, and myria, ashes, cinders. Hot ashes.

Take hot *embers*, and put them about a bottle filled with new beer, almost to the very neck: let the bottle be well stopped, lest it fly out; and continue it, renewing the *embers* every day for the space of ten days.
*Bacon's Natural History.*

Good deeds in this life are coals raked up in *embers*, to make a fire next day. *Overbury.*

While thus heaven's highest counsels, by the low
Footsteps of their effects, he traced too well,
He tost his troubled eyes, *embers* that glow
Now with new rage, and wax too hot for hell.
*Crashaw.*

If the air will not permit,
Some still removed place will fit,
While glowing *embers* through the room
Teach light to counterfeit a gloom. *Milton.*

He said, and rose, as holy zeal inspires;
He rakes hot *embers*, and renews the fires.
*Dryden's Virgil.*

These scenes, their story not unknown
Arise, and make again your own;
Snatch from the ashes of your sires
The *embers* of your former fires. *Byron.*

EM'BER-DAYS, *n. s.*
EM'BERING, *n. s.*
EM'BER-WEEK.
Sax. ymbren. The first two substantives are synonymous. Of ember-week, Dr. Johnson says, the origin has been much controverted: some derive it from embers or ashes strewed by penitents on their heads; but Nelson decides in favor of Mareschal, who derives it from ymbren or embren a course or circumvolution. A week in which an ember-day falls.

The *ember-days* at the four seasons are the Wednesday, Friday, and Saturday after the first Sunday in Lent, the feast of Pentecost, September 14, December 14. *Common Prayer.*

For causes good so many ways,
Keep *emberings* well, and fasting days;
What law commands, we ought to obey,
For Friday, Saturn, and Wednesday. *Tusser*

Stated times appointed for fasting are Lent, and the four seasons of the year called *ember-weeks.*
*Ayliffe's Parergon.*

EMBER-WEEKS, by the canonists, are called quatuor anni tempora, the four cardinal seasons, on which the circle of the year turns; and hence Henshaw takes the word to have been formed, viz. by corruption, from tempora. They are now chiefly taken notice of, on account of the ordination of priests and deacons; because the canon appoints the Sundays next succeeding the ember weeks, for the solemn times of ordination; though the bishops may ordain on any Sunday or holiday.

EMBEZ'ZLE, *v. a.*
EMBEZ'ZLEMENT, *n. s.*
A corruption of *imbecile* Dr. Johnson says; but it seems better derived from Old Fr. *besler* or *embesler* to filch. To pilfer, steal; dishonestly appropriate: hence to squander or waste.

He had *embezzled* the king's treasure, and extorted money by way of loan from all men. *Hayward.*

When thou hast *embezzled* all thy store,
Where's all thy father left? *Dryden's Pers.*

EMBEZZLEMENT. For protecting masters against embezzlements by their clerks and servants, stat. 39 Geo. III. cap. 35, enacts, That servants or clerks, or persons employed for the purpose, or in the capacity of servants or clerks, who shall, by virtue of such employment, receive or take into their possession any money, goods, bond, bill, note, banker's draft, or other valuable security or effects, for, or in the name, or on account of, their master or employer, and who shall fraudulently embezzle, secrete, or make away with the same, or any part thereof; every such offender shall be deemed to have feloniously stolen the same from his master or employer, for whose use, or on whose account, the same was delivered to, or taken into the possession of such servant, clerk, or other person so employed, although such money, goods, bond, bills, notes

banker's drafts, or other valuable security, was or were no otherwise received into the possession of his or their servants, clerk, or other person so employed; and every such offender, his adviser, procurer, aider, or abettor, being thereof lawfully convicted or attainted, shall be liable to be transported to such part beyond the seas as his majesty, by and with the advice of his privy council, shall appoint, for any term not exceeding fourteen years, in the discretion of the court before whom such offender shall be convicted or adjudged.

EMBLA'ZE, *v. a.* } Fr. *blasonner*. See
EMBLAZ'ON, *v. a.* } BLAZE. To adorn with
EMBLAZ'ONRY, *n. s.* } glittering embellishments; to exhibit in glaring colors, and particularly with heraldic honors or ensigns.

Nor shall this blood be wiped from thy point,
But thou shalt wear it as a herald's coat,
T' *emblaze* the honour which thy master got.
*Shakspeare.*

We find Augustus, for some petty conquest *emblazoned* by the poets to the highest pitch.
*Hakewill on Providence.*

He from the glittering staff unfurled
The imperial ensign, streaming to the wind,
With gems and golden lustre rich *emblazed*,
Seraphick arms and trophies.
*Milton's Paradise Lost.*

Him round
A globe of fiery seraphim inclosed
With bright *emblazonry* and horrent arms. *Id.*

No weeping orphan saw his father's stores,
Our shrines irradiate, or *emblaze* the floors.
*Pope.*

Now high in air, the imperial standard waves,
*Emblazoned* rich with gold and glittering gems,
And like a sheet of fire through the dun gloom
Streaming meteorous. *Somerville.*

EM'BLEM, *n. s.* & *v. a.* } Fr. *embleme*; Ital.
EMBLEMAT'IC, *adj.* } Span. Portug. and
EMBLEMAT'ICAL, *adv.* } Lat. *emblema*; Gr.
EMBLEMAT'ICALLY, } εμβλημα, from the
EMBLEM'ATIST. } verb εμβαλλεσθαι, to insert. i. e. εν and βαλλω to throw. An ornament inserted or thrown into a piece of workmanship: to represent by emblems: emblematic and emblematical are representing pictorially, or by emblems; emblematist he who invents or uses them.

She had all the royal makings of a queen,
The rod, and bird of peace, and all such *emblems*,
Laid nobly on her. *Shakspeare. Henry VII.*

Poets can boast of nothing but a lean visage peering out of a seam-rent suit, the very *emblems* of beggary. *Ben Jonson.*

If you draw your beast in an *emblem*, shew a landscape of the country natural to the beast.
*Peacham on Drawing.*

Gentle Thames,
The mighty master's *emblem*, in whose face
Sate meekness, heightened with majestick grace.
*Denham.*

These fables are still maintained by symbolical writers, *emblematists*, and heralds.
*Browne's Vulgar Errours.*

Others have spoken *emblematically* and hieroglyphically, as the Egyptians; and the phœnix was the hieroglyphick of the sun. *Id.*

The primitive sight of elements doth fitly *emblem* that of opinions. *Glanville's Scepsis.*

The poets contribute to the explication of reverses purely *emblematical*, or when the persons are allegorical. *Addison.*

In the well framed models,
With *emblematick* skill and mystick order,
Thou shew'dst where towers on battlements should rise,
Where gates should open, or where walls should compass. *Prior.*

He took a great stone, and put it up under the oak, *emblematically* joining the two great elements of masonry. *Swift.*

Some when they die, die all; their mouldering clay,
Is but an *emblem* of their memories;
The space quite closes up through which they passed.
*Young.*

Sweet stream, that winds through yonder glade,
Apt *emblem* of a virtuous maid—
Silent and chaste she steals along,
Far from the world's gay busy throng. *Cowper.*

Now as these were *emblematic* exhibitions, they must have been as well adapted to the purposes of sculpture as of poetry, which indeed does not seem to have been uncommon, since one compartment of figures in the shield of Æneas represented the regions of Tartarus. *Darwin.*

Instructive *emblem* of this mortal state!
Where scenes as various every hour arise
In swift succession, which the hand of fate
Presents, then snatches from our wondering eyes.
*Beattie.*

And, bright around with quivering beams beset,
Her *emblem* sparkles o'er the minaret. *Byron.*

*An* EMBLEM, is a kind of painted ænigma, which, representing some obvious history, instructs us in some moral truth. See ÆNIGMA, &c Such is that very significant image of Scævola holding his hand in the fire; with the words, 'Agere et pati fortiter Romanum est, To do and suffer courageously is Roman.' The emblem is somewhat plainer than the ænigma. Gale defines emblem an ingenious picture, representing one thing to the eye, and another to the understanding. The Greeks also gave the name EMBLEMS, εμβληματα, from εμβαλλειν, to insert, to inlayed or Mosaic works, and even to all kinds of ornaments of vases, moveables, garments, &c. Cicero, reproaching Verres with having plundered statues and fine wrought works from the Sicilians, calls the ornaments fixed to them, and which on occasion might be separated, emblemata.

EMBLEMENTS, in English law, Fr. from emblaver, q. d semer en blé, to sow with wheat, is a term strictly signifying the profits of lands sown; though sometimes used more largely for any profits arising, and growing naturally from the ground; as grass, fruit, &c.

If a tenant for life sow the land, and die before harvest, his representatives shall have the emblements to compensate for the labor and expense of tilling, manuring, and sowing the lands, and also for the encouragement of husbandry; and not he in reversion. But if the tenant for years sow the land, and before severance the term expires, or the estate for life be determined by the tenant's own act, as by forfeiture for waste committed, or if a tenant during widowhood think proper to marry, then the lessor, or he in reversion shall have the emblements, and not

the lessee. The advantages of emblements are extended to the parochial clergy by 28 Hen. VIII. cap. 11.

All the cases of emblements turn upon the point of uncertainty; since the tenant could not possibly know when his landlord would determine his will, and therefore could make no provision against it; and having sown the land, which is for the good of the public, upon a reasonable presumption, the law will not suffer him to be a loser by it. But it is otherwise, and upon reason equally good, where the tenant himself determines the will; for in this case, the landlord shall have the profits of the land. Co. Litt. 55, 56.

Emblements are distinct from the real estate in the land, and are subject to many, though not all, the incidents attending personal chattels. They were devisable by testament before the statute of wills (Perk. sec. 412); and at the death of the owner, shall vest in his executor, and not his heir; they are forfeitable by outlawry in a personal action (Bro. Abr. tit. emblements, 21; 5 Rep. 116); and by the statute 11 Geo. II. cap. 19, though not by common law (1 Roll. Abr. 666), they may be distrained for rent arrear. Although the emblements are assets in the hands of the executor, are forfeitable upon outlawry, and distrainable for rent, they are not in other respects considered as personal chattels; and particularly, they are not the object of larceny, before they are severed from the ground. 3 Inst. 109.

Where a lord enters on his tenant for a forfeiture, he shall have the corn on the ground. 4 Rep. 21. Though if a feme copyholder for her widowhood sows the land, and before severance takes husband, so that her estate is determined, the lord shall have the emblements; yet if such a feme copyholder, durante viduitate, leases for one year according to custom, and the lessee sows the land, and afterwards the copyholder takes husband, the lessee shall have the corn. If a husband holds lands for life, in right of his wife, and sow the land, and after she dies before severance, he shall have the emblements. Dyer, 316. 1 Nels. Ab. 701. And where the wife has an estate for years, life, or in fee, and the husband sows the land, and dies, his executors shall have the corn. 1 Nels. 702. But if the husband and wife are joint-tenants, though the husband sow the land with corn, and dies before ripe, the wife, and not his executors, shall have the corn, she being the surviving joint-tenant. Co. Lit. 199.

A widow endowed with lands sown, shall have the emblements, and not the heir. 2 Inst. 81. And a tenant in dower may dispose of corn sown on the ground; or it may go to her executors, if she die before severance. 2 Inst. 80, 81.

If a tenant by statute-merchant sow the land, and before severance a casual profit happens, by which he is satisfied, yet he shall have the corn. Lands sown are delivered in execution upon an extent, the person to whom delivered shall have the corn on the ground. 2 Leon. 54. And judgment was given against a person, and then he sowed the land, and brought a writ of error to reverse the judgment, but it was affirmed; and adjudged that the recoverer shall have the corn. 2 Bulst. 213.

When a disseisor sows the land, and afterwards cuts the corn, but before it is carried away the disseisee enters, the disseisee shall have the corn. Dyer, 31. 11 Rep. 52. A person seised in fee of land dies, having a daughter, and his wife privement enseint with a son; the daughter enters and sows the land, and before severance of the corn, the son is born; in this case the daughter shall have the corn, her estate being lawful, and defeated by the act of God; and it is for the public good that the land should be sown.

If a man seised in fee-simple sows land, and then devises the land by will, and dies before severance; the devisee shall have the corn; and not the devisor's executors. Winch. 52. Cro. Eliz. 61. If a person devises his lands sown, and says nothing of the corn, the corn shall go with the land to the devisee: and when a man seised of land, in fee or in tail, sows it, and dies without will, it goes to the executor, and not to the heir. 10 Ed. IV. 1 b. 21 H. VI. 30 a. 37 H. VI. 35 b. A devisee for life dies, he in remainder shall have the emblements with the land.

EMBOD'Y, *v. a.* & *v. n.* Em and body. To put into or invest with a bodily, corporeal, or material shape; to draw together soldiers into a body; to be united in one body or mass.

> Eke enrooted deep must be that tree,
> Whose big *embodied* braunches shall not lie,
> Till they to heaven's hight forth stretched bee.
>
> *Spenser. Faerie Queene.*

> The local militia when not drawn out and *embodied*, shall be entitled to the same pay, clothing and allowances, as the regular militia are when not *embodied*; and when drawn out and *embodied*, shall be entitled to the same pay, clothing, and allowances, for themselves and families, as his majesty's other militia forces when drawn out and *embodied*.
>
> *Local Militia Act*, 48 *Geo. III.* c. 3.

> If there be no such thing as a *disembodied* spirit would not our Lord have shewn them their error? Instead of this he confirms them in their opinion, &c.
>
> *Clarke on Luke* xxiv. 37.

EMBOLD'EN, *v. a.* & *v. n.* To encourage or be encouraged; to strengthen or feel confirmed in resolution.

> Shall vain words have an end; or what *emboldeneth* thee that thou answerest? *Job* xvi. 3.

> Shall not the conscience of him which is weak be *emboldened* to eat those things which are offered to idols? 1 *Cor.* viii. 10.

> Yet nathemore by his bold hartie speach
> Could his blood-frozen hart *emboldened* bee,
> But through his boldness rather feare did reach.
>
> *Spenser. Faerie Queene.*

> Nothing *emboldens* sin so much as mercy.
>
> *Shakspeare.*

E'MBOLISM, *n. s.* Gr. εμβολισμος, from εν and βαλλω. See EMBLEM. Intercalation; insertion of days or years to produce regularity and equation of time.

> The civil constitutions of the year were after different manners in several nations; some using the sun's year, but in divers fashions; and some following the moon, finding out *embolisms* or equations, even to the

addition of whole months, to make all as even as they could. *Holder on Time.*

EMBOLISM, or EMBOLISMUS. As the Greeks made use of the lunar year, which is only 354 days, in order to bring it to the solar, which is 365 days, they had every two or three years an embolism, i. e. they added a fifteenth lunar month every second or third year, which additional month they called εμβολιμαιος, embolimœus, because inserted, or intercalated.

E'MBOLUS, *n. s.* Gr. εμβολος. Any thing inserted and acting in another, as the sucker in a pump.

Our members make a sort of an hydraulick engine, in which a chemical liquor, resembling blood, is driven through elastick channels by an *embolus*, like the heart. *Arbuthnot.*

EMBO'SOM, *v. a.* Em and bosom. To receive into the bosom, heart, or affections: hence to enclose; to shelter.

His house *embosomed* in the grove,
Sacred to social life and love. *Pope.*

EMBOSS', *v. a.* Fr. *emboister, embosquer;* Ital. *imboscare.* To enclose, as in a box or bush.

The knight his thrilliant spear again essayed
In his brass-plated body to *emboss.* *Spenser.*
And in the way, as she did weep and wail,
A knight her met, in mighty arms *embossed.*
*Id. Faerie Queene.*
Like that self-begotten bird
In the Arabian woods *embost.*
*Milton's Agonistes.*

EMBOSS', *v. a.* & *v. n.* } Fr. *embosser, bosse,*
EMBOSS'MENT. } a protuberance. To cause to rise or swell in tumors, or other projections: hence to sculpture in relief.

Oh, he is more mad
Than Telamon for his shield; the boar of Thessaly
Was never so *embost.* *Shakspeare.*

Timon hath made his everlasting mansion
Upon the beached verge of the salt flood;
Which once a-day, with his *embossed* froth,
The turbulent surge shall cover. *Id. Timon.*
Thou art a bile,
A plague sore, or *embossed* carbuncle,
In my corrupted blood. *Id. King Lear.*

I wish also, in the very middle, a fair mount, with three ascents and alleys, enough for four to walk abreast; which I would have to be perfect circles, without any bulwarks or *embossments.*
*Bacon's Essays.*

Botches and blains must all his flesh *emboss,*
And all his people. *Milton's Paradise Lost.*

When a deer is hard run and foams at the mouth, he is said to be *embost:* a dog also, when he is strained with hard running, especially upon hard ground, will have his knees swelled, and then he is said to be *embost,* from bosse, French, a tumour.
*Hanmer.*

All crowd in heaps, as at a night alarm
The bees drive out upon each other's backs,
T' *emboss* their hives in clusters.
*Dryden. Don Sebastian.*
Then o'er the lofty gate his art *embossed*
Androgeo's death, and offerings to his ghost.
*Id. Virgil.*

They are at a loss about the word pendentis; some fancy it expresses only the great *embossment* of the figure, others believe it hung off the helmet in alto relievo. *Addison on Italy.*

Averse they fly, or with rebellious aim
Chase him from thence: needless their impious deed,
The huntsman knows him by a thousand marks,
Black and *imbost.* *Somerville's Chase.*

While thus through all the stages thou hast pushed
Of treeship—first a seedling, hid in grass;
Then twig; then sapling; and, as century rolled
Slow after century, a giant-bulk
Of girth enormous, with moss-cushioned root
Upheaved above the soil, and sides *embossed*
With prominent wens globose—till at the last
The rottenness, which time is charged to inflict
On other mighty ones, found also thee. *Cowper.*

EMBOTHRIUM, in botany, a genus of the monogynia order, and tetrandria class of plants: CAL. none, COR. four linear-oblique petals; stamina four very short filaments; antheræ large, oblong, seated within the cavity of the petal. Pericarp a round unilocular follicle, sharpened at both ends: SEED four or five in number, egg-shaped, and compressed. Species eight elegant shrubs of New Holland and South America, bearing white and red flowers.

EMBO'TTLE, *v. a.* Fr. *bouteille.* To include in bottles; to bottle.

Stirom, firmest fruit
*Embottled,* long as Priamean Troy
Withstood the Greeks, endures. *Philips.*

EMBO'WEL, *v. a.* Old Fr. *emboullecz,* from bowel. To eviscerate; to deprive of the entrails; to exenterate.

*Embowelled* will I see thee by and by;
Till then, in blood, by noble Percy lye.
*Shakspeare.*
The schools,
*Embowelled* of their doctrine, have left off
The danger to itself. *Id.*
The roar
*Embowelled* with outrageous noise the air,
And all her entrails tore. *Milton's Paradise Lost.*
Fossils and minerals that the *embowelled* earth
Displays. *Philips.*

EMBOW'ER, *v. n.* & *v. a.* Em and bower. To receive or dwell within a bower; to build as a bower; to encircle as within a bower.

The small birds, in their wide boughs *embowering*
Chaunted their sundry tunes. *Spenser.*
—— On the mingling boughs they sit *embowered*
All the hot noon. *Thomson.*
Look where he comes—in this *embowered* alcove
Stand close concealed, and see a statue move:
Lips busy, and eyes fixed, foot falling slow,
Arms hanging idly down, hands clasped below,
Interpret to the marking eye distress,
Such as its symptoms can alone express. *Cowper.*

EMBRACE', *v. a., v. n.* & *n. s.* } Fr. *embras-*
EMBRACE'MENT, *n. s.* } *ser;* Ital. *ab-*
EMBRA'CER. } *bracciare;* Lat. *brachium,* the arm. To enclose, or take within the arms; to fondle; hence to seize with ardor, and to comprehend generally: as a neuter verb it is used by Shakspeare for to join in an embrace. As a noun embrace and embracement are alike, a fond clasping or enclosing within the arms; hence admission or reception; comprehension; enclosure.

And fyrst vppon the louely shall she smile,
And frendly on the cast her wandering eyes,
*Embrace* the in her armes, and for a whyle,
Put the and kepe the in a fooles paradise.
*Sir T. More.*

*Here, between the armies,*
*Let's drink together friendly, and embrace.*
*Shakspeare.*

Let me *embrace* with old Vicentio;
And wander we to see thy honest son,
Who will of thy arrival be full joyous. *Id.*

Fenton, Heaven give thee joy!
What cannot be eschewed, must be *embraced.*
*Id.*

I would freelier rejoice in that absence, wherein he won honour, than in the *embracements* of his bed, where he would shew most love. *Id. Coriolanus.*

I take it, your own business calls on you,
And you *embrace* the occasion to depart. *Id.*

The parts in man's body easily reparable, as spirits, blood, and flesh, die in the *embracements* of the parts hardly reparable, as bones, nerves, and membranes. *Bacon's Natural History.*

At first, her mother earth she holdeth dear,
And doth *embrace* the world, and worldly things.
*Davies.*

Nor can her wide *embracements* filled be. *Id.*

Yet are they the greatest *embracers* of pleasure of any other upon earth; and they esteem of pearls as pebbles, so they may satisfy their gust, in point of pleasure or revenge. *Howel.*

Thames, the most loved of all the ocean's sons
By his old sire, to his *embraces* runs. *Denham.*

Low at his feet a spacious plain is placed,
Between the mountain and the stream *embraced.*
*Id.*

There cherishing one another with dear, though chaste *embracements*, with sweet, though cold kisses, it might seem that Love was come to play him there without darts. *Sidney.*

These beasts, fighting with any man, stand upon their hinder feet, and so this did, being ready to give me a shrewd *embracement.* *Id.*

They who are represented by the wise virgins, *embraced* the profession of the Christian religion, as the foolish virgins also had done. *Tillotson.*

*Embrace* again, my sons! be foes no more;
Nor stain your country with her children's gore.
*Dryden.*

And I have unbiasedly *embraced* what, upon a fair inquiry, appeared so to me. If I must believe for myself, it is unavoidable that I must understand for myself. *Locke.*

If a man can be assured of any thing, without having examined, what is there that he may not *embrace* for truth? *Id.*

Can you e'er forget
The fond *embraces*, and repeated blessings
Which you drew from him in your last farewell?
*Addison.*

Eternity will not efface
Those records dear of transports past;
Thy image at our last *embrace*;
Ah! little thought we 'twas our last!
*Burns.*

EMBRA'SURE, *n. s.* Fr. *embrasure.* An aperture in the wall, through which the cannon is pointed; part of a battlement.

EMBRASURE, in architecture, the enlargement made of the aperture of a door or window, on the inside of the wall; its use being to give the greater play for the opening of the door or casement, or to admit the more light.

EMBR'AVE, *v. a.* From brave. To decorate; to embellish; to deck; to grace; to adorn. Not now in use.

*So, both agree their bodies to engrave;*
*The great earth's womb they open to the sky,*
*And, with sad cypress, seemly it embrave.*
*Faerie Queene.*

EM'BROCATE, *v. a.* } Fr. *embrocation*, from
EMBROCA'TION, *n. s.* } Gr. εμβρεχειν i. e. εν and βρεχειν, to damp or wet. To moisten with medicinal applications: the act of so doing; or the lotion is an embrocation.

I returned her a glass with oil of roses and vinegar, to *embrocate* her arm.
*Wiseman on Inflammation.*

We endeavoured to ease by discutient and emollient cataplasms, and *embrocations* of various sorts.
*Id. Surgery.*

*An* EMBROCATION, in surgery and pharmacy, is an external kind of remedy, which consists in an irrigation of the part affected, with some proper liquor, as oils, spirits, &c., by means of a woollen or linen cloth, or a sponge, dipped in the same.

EMBROI'DER, *v. a.* } Fr. *broder*, a com-
EMBROI'DERER, *n. s.* } pound of em and BROI-
EMBROI'DERY, *n. s.* } DER, which see. To border or decorate with ornaments; to diversify with raised needlework: embroiderer is the party executing this kind of work; and embroidery, the work performed: hence also, variegated colors generally.

Blue silk and purple, the work of the *embroiderer.*
*Eccles.*

Write,
In emerald tuffs, flowers purfled, blue and white,
Like saphire, pearl, in rich *embroidery*,
Buckled below fair knighthood's bending knee.
*Shakspeare.*

We see in needleworks and *embroideries*, it is more pleasing to have a lively work upon a sad and solemn ground, than to have a dark and melancholy work upon a lightsome ground: judge, therefore, of the pleasure of the heart by the pleasure of the eye.
*Bacon.*

Quality alone should only serve to make a shew in the *embroidered* part of the government; but ignorance though never so well born, should never be admitted to spoil the public business. *Saville.*

Such an accumulation of favours is like a kind of *embroidering*, or lifting of one favour upon another.
*Wotton.*

Envy rages as much in a sordid affected dress, as in all the silks and *embroideries* which the excess of the age and the folly of youth delight to be adorned with. *Clarendon.*

*Embroidered* so with flowers it had stood
That it became a garden of a wood. *Waller.*

Let no virgin be allowed to receive her lover, but in a suit of her own *embroidering.*
*Spectator*, No. 606.

If the natural *embroidery* of the meadows were helpt and improved by art, a man might make a pretty landskip of his own possessions. *Id.* No. 414.

Next these a youthful train their vows expressed,
With feathers crowned, with gay *embroidery* dressed.
*Pope.*

*Embroidered* purple clothes the golden beds,
This slave the floor, and that the table spreads.
*Id.*

How sweetly mutable yon orient hues,
As morn's fair hand her opening roses strews;
How bright, when Iris blending many a ray,
Binds in *embroidered* wreath the brow of day.
*Darwin.*

Embroidery is a work in gold, silver, or silk thread, wrought by the needle upon cloth, stuffs, or muslin, into various figures. In embroidering stuffs, the work is performed in a kind of loom; because the more the piece is stretched, the easier it is worked. As to muslin, they spread it upon a pattern ready designed; and sometimes, before it is stretched upon the pattern, it is starched to make it more easy to handle. Embroidery on the loom is less tedious than the other, in which, while they work flowers, all the threads of the muslin, both lengthways and breadthways, must be continually counted; but, on the other hand, this last is much richer in points, and susceptible of greater variety. Cloths too much milled are scarcely susceptible of this ornament, and in effect we seldom see them embroidered. The thinnest muslins are left for this purpose; and they are embroidered to the greatest perfection in Saxony. By stat. 22 Geo. II. c. 36, no foreign embroidery, or gold and silver brocade, shall be imported, upon pain of being forfeited and burnt, and penalty of £100 for each piece. No person shall sell, or expose to sale, any foreign embroidery, gold or silver thread, lace, fringe, brocade, or make up the same into any garment, on pain of having it forfeited and burnt, and penalty of £100. All such embroidery, &c., may be seized and burnt; and the mercer, &c., in whose custody it was found, shall forfeit £100.

EMBRO'IL, *v. a.* Fr. *brouiller*. To disturb; confuse; distract; throw into commotion; to involve in dissension or discord.

I had no passion, design, or preparation to *embroil* my kingdom in a civil war. *King Charles.*

Rumour next, and chance,
And tumult and confusion, all *embroiled*,
And discord with a thousand various mouths.
*Milton.*

When she found her venom spread so far,
The royal house *embroiled* in civil war,
Raised on her dusky wings she cleaves the skies.
*Dryden.*

Supposing a government wherein the person of the chief magistrate is not thus sacred; yet this doctrine of the lawfulness of resisting all unlawful exercises of his power, will not upon every slight occasion indanger him, or *embroil* the government; for where the injured party may be relieved, and his damages repaired by appeal to the law, there can be no pretence for force. *Locke.*

The Christian antiquities at Rome, though of a fresher date, are so *embroiled* with fable and legend, that one receives but little satisfaction.
*Addison on Italy.*

Embroil', *v. a.* Em and broil, to roast on the fire. See Broil.

That knowledge, for which we boldly attempt to rifle God's cabinet, should, like the coal from the altar, serve only to *embroil* and consume the sacrilegious invaders. *Decay of Piety.*

EMBROTHEL, *v. a.* Brothel, brodel. To enclose in a brothel.

Men, which chuse
Law practice for mere gain, boldly repute,
Worse than *embrotheled* strumpets prostitute.
*Donne.*

EMBRUN, an old town of France, situated on a steep rock near the Durance, in the department of the Upper Alps. It is walled, and has a citadel erected by Louis XIV. Embrun was formerly an archiepiscopal see, but is now united with that of Aix. Population 3150. Fifty-five miles south-west of Grenoble.

EM'BRYO, *n. s.*
Em'bryon, *n. s.* & *adj.*
Embryot'ic, *adj.*
} Fr. *embryon;* Span. *embrion;* Ital. *embrione;* Lat. *embryo*; Gr. εμβρυον, i.e. εν (γαστρος, the belly) βρυον, growing. Any thing in an imperfect but growing state, applied particularly to the human fœtus.

The bringing forth of living creatures may be accelerated, if the *embryo* ripeneth and perfecteth sooner.
*Bacon.*

The earth was formed, but in the womb as yet
Of waters, *embryon* immature involved
Appeared not. *Milton's Paradise Lost.*

—— Hot, cold, moist, and dry, four champions fierce
Strive here for mastery, and to battle bring
Their *embryon* atoms. *Id.*

An exclusion before conformation, before the birth can bear the name of the parent, or be so much as properly called an *embryon*.
*Browne's Vulgar Errours.*

And yet if it comes in question, whether a plant, that lies ready formed in the seed, have life; whether the *embryo* of an egg before incubation, or a man in a swoon without sense or motion, be alive, or no? it is easy to perceive, that a clear distinct settled idea does not always accompany the use of so known a word, as that of life is. *Locke.*

In that dark womb are the signs and rudiments of an *embryo* world *Burnet's Theory.*

When the crude *embryo* careful nature breeds,
See how she works, and how her work proceeds.
*Blackmore.*

The company little suspected what a noble work I had then in *embryo*. *Swift.*

While the promised fruit
Lies yet a little *embryo*, unperceived
Within its crimson folds. *Thomson's Spring.*

Some, bounded to a district-space,
Explore at large man's infant race,
To mark the *embryotic* trace
Of rustic Bard;
And careful note each opening grace,
A guide and guard. *Burns.*

Sylphs! as you hover on ethereal wing,
Brood the green children of parturient spring!—
Where in their bursting cells my *embryons* rest,
I charge you, guard the vegetable nest. *Darwin.*

Nor yet for the ravage of winter I mourn;
Kind Nature the *embryo* blossom will save:
But when shall spring visit the mouldering urn?
O when shall it dawn on the night of the grave
*Beattie.*

It has the earliest intelligence of intended preferments that will reflect honour on the patrons; and *embryo* promotions of modest gentlemen, who know nothing of the matter themselves. *Sheridan.*

EME, *n. s.* Sax. eame. Uncle. Now obsolete. See Eame.

Whilst they were young, Cassibelan their *eme*,
Was by the people chosen in their stead;
Who on him took the royal diadem,
And goodly well it long time governed.

**EMEND,'** *v. a.* French, *emendation;* Ialian, *emendatione;* Latin, *emendatio.* See AMEND. To correct.
**EMENDA'TION,** *n. s.*
**EMENDA'TOR,** *n. s.*
**EMEN'DATORY,** *adj.*

Emendation is the correction made; and emendator, he who makes it; emendatory, is corrective.

> Have us excused, that we no better do,
> Another time to *emende* it if we can.
> *Mystery of Candlemas Day.*

The Roman *emendators* of Gratian themselves know not how to trust it. *Bp. Cosin.*

The essence and relation of any thing in being, is fitted beyond any *emendation,* for its action and use; and shews it to proceed from a mind of the highest understanding. *Grew.*

He had, what is the first requisite to *emendatory* criticism, that intuition by which the Poet's intention is immediately discovered. *Johnson.*

EM'ERALD, *n. s.* Fr. *emeraude;* Ital. *smeraldo;* Span. and Port. *esmeralda;* Teut. and Belg. *schmaragd;* Lat. *smaragdus;* Arab. *zmarad;* Armen. *zmaragthos;* Gr. *σμαραγδος,* from the verb *σμαρασσω,* luceo, to shine. A precious stone of considerable beauty and value.

Do you not see the grasses how in colour they excel the *emerald?* *Sidney.*

The *emerald* is a bright grass green; it is found in fissures of rocks, along with copper ores. *Woodward on Fossils.*

> Nor deeper verdure dies the robe of Spring,
> When first she gives it to the southern gale,
> Than the green *emerald* shows. *Thomson's Summer.*

The *emerald* is evidently the same with the ancient smaragdus; and, in its most perfect state, is perhaps the most beautiful of all the gems. The rough *emerald* is usually of a very bright and naturally polished surface, and is ever of a pure and beautiful green, without the admixture of any other colour. The oriental *emerald* is of the hardness of the saphire and ruby, and is second only to the diamond in lustre and brightness. *Hill on Fossils.*

> With verdant light the modest *emeralds* glow,
> Blue sapphires glare, and rubies blush below;
> Light piers of lazuli the dome surround,
> And pictured mochoes tesselate the ground.
> *Darwin.*

> In noon's bright blaze thy vermil vest unfold,
> And wave thy *emerald* banner starred with gold. *Id.*

> Throned in her *emerald*-car, see Spring appear!
> (As fancy wills the landscape starts to view)
> Her *emerald*-car the youthful Zephyrs bear,
> Fanning her bosom with their pinions blue.
> *Beattie.*

> Light be the turf of thy tomb!
> May its verdure like *emeralds* be:
> There should not be the shadow of gloom,
> In ought that reminds us of thee. *Byron.*

EMERALD. This genus contains two species, the prismatic and rhomboidal.

Prismatic emerald, Euclase of Haüy. Its colors are green, of various shades, and sometimes sky blue. It is found only crystallised. The primitive form is a prism of 133° 24'. Lustre splendent. Cleavage perfect in the direction of the smaller diagonals of the prism. Transparent. Refracts double. Harder than quartz, but softer than topaz. Easily frangible. Specific gravity 2·9 to 3·3. Loses transparency, and then melts before the blow-pipe. Its constituents are 35 to 36 silica, 18 to 19 alumina, 14 to 15 glucina, 2 to 3 iron, and 27 to 31 loss. The last is chiefly water, and in some measure alkali. Found in Peru and Brasil. It is a beautiful mineral, but two brittle for jewellery.

Rhomboidal emerald, of which there are two sub-species, the precious emerald and the beryl. Precious emerald is well characterised by its green color, of various depths. It is generally crystallised. The primitive form is an equiangular six-sided prism, on which various truncations are found. Lustre splendent. Cleavage straight and four-fold. Transparent. Moderate double refraction. Nearly as hard as topaz. Specific gravity 2·6 to 2·77. Heated to a moderate degree, it becomes of a blue color, but recovers its tint on cooling. At a high heat, it fuses into a white vesicular glass. Its constituents are silica 64·5, alumina 16, glucina 13, oxide of chrome 3·25, lime 1·6, water 2. It occurs in drusy cavities, along with iron pyrites, calcareous spar, and quartz, in veins that traverse clay-slate. The most beautiful emeralds come from Peru. As a gem it is valued next to the ruby. The emerald is perhaps the most beautiful of all the gems; and according to Wallerius, when heated in the fire, changes its color to a deep blue, and becomes phosphorescent; but recovers its green when cold. When pulverised it has a white appearance, and with borax melts to a very thin and colorless glass. It becomes electric by being rubbed, and some have the property of the tourmalin, viz. of being electrified by heat, and in that state attracting ashes or other light substances; though after having attracted the ashes, they retain them without any signs of repulsion. Pliny mentions twelve different kinds of these precious stones; though it appears, from the vast size of some of them, that they must have been only certain kinds of green spar, or other green stone, which at that time went under the name of emerald among the ancients. Theophrastus, however, mentions one four cubits long and three broad likewise an obelisk composed of only four emeralds, the whole length being forty cubits, and the breadth from four to two.

EMERGE,' *v. n.* Lat. *emergo,* from *e* privative and *mergo,* to plunge. To rise out of a fluid; to issue; proceed; to rise into view, and hence out of obscurity.
EMERG'ENCE, *n. s.*
EMERG'ENCY,
EMERG'ENT, *adj.*
EMER'SION, *n. s.*

Emergence and emergency are the act of rising in this way; also (metaphorically) any sudden casualty or occurrence. Emersion is confined to the rising out of a fluid or out of obscurity; as in its particular application to the re-appearance of a star. Emergent is proceeding or issuing forth, from something; and is sometimes used for sudden, casual, unexpected.

The man that is once hated, both his good and his evil deeds oppress him; he is not easily *emergent.* *Ben Jonson.*

All the lords declared, that, upon any *emergent* occasion, they would mount their servants upon their horses. *Clarendon.*

> Immediately the mountains huge appear
> *Emergent,* and their broad bare backs upheave
> Into the clouds. *Milton*

Most of our rarities have been found out by casual *emergency*, and have been the works of time and chance rather than of philosophy. *Glanville's Scepsis.*

We have read of a tyrant, who tried to prevent the *emergence* of murdered bodies. *Browne's Vulgar Errours.*

The time was in the heliacal *emersion*, when it becomes at greatest distance from the sun. *Id.*

The *emergency* of colours, upon coalition of the particles of such bodies, as were neither of them of the colour of that mixture whereof they are ingredients, is very well worth our attentive observation. *Boyle on Colours.*

They *emerged*, to the upper part of the spirit of wine, as much of them as lay immersed in the spirit. *Boyle.*

Thetis, not unmindful of her son,
*Emerging* from the deep, to beg her boon,
Pursued their track. *Dryden's Homer.*

The stoics held a fatality, and a fixed unalterable course of events; but then they held also, that they fell out by a necessity *emergent* from, and inherent in, the things themselves, which God himself could not alter. *South.*

The mountains *emerged* and became dry land again, when the waters retired. *Burnet's Theory.*

In any case of *emergency*, he would employ the whole wealth of his empire, which he had thus amassed together in his subterraneous exchequer. *Addison's Freeholder.*

If the prism was turned about its axis that way, which made the rays *emerge* more obliquely out of the second refracting surface of the prism, the image soon became an inch or two longer, or more. *Newton's Opticks.*

The white colour of all refracted light, at its very first *emergence*, where it appears as white as before its incidence, is compounded of various colours. *Id.*

When, from dewy shade *emerging* bright,
Aurora streaks the sky with orient light,
Let each deplore his dead. *Pope's Odyssey.*

Then from ancient gloom *emerged*
A rising world. *Thomson's Summer.*

In this situation of Europe, Scotland, which had hitherto wasted her strength between France and England, *emerged* from her obscurity, took her station in the system, and began to have some influence upon the fate of distant nations. *Robertson. History of Scotland.*

As one, who, long detained on foreign shores,
Pants to return, and when he sees afar
His country's weather-bleached, and battered rocks,
From the green wave *emerging*, darts an eye
Radiant with joy towards the happy land;
So I with animated hopes behold. *Cowper.*

—Hither, *emerging* from yon orient skies,
Botanic Goddess! bend thy radiant eyes;
O'er these soft scenes assume thy gentle reign
Pomona, Ceres, Flora, in thy train. *Darwin.*

From silent mountains, straight, with startling sound,
Torrents are hurled; green hills *emerge*; and lo,
The trees with foliage, cliffs with flowers are crowned;
Pure rills through vales of verdure warbling go;
And wonder, love, and joy, the peasant's heart o'erflow. *Beattie.*

Emersion, in astronomy, is used when the sun, moon, or other planet, begins to re-appear, after its having been eclipsed, or hid by the interposition of the moon, earth, or other body. The difference of longitude is sometimes found by observing the immersions and emersions of the first of Jupiter's satellites. The immersions are observed from the time of Jupiter's being in conjunction with the sun to his opposition; and the emersion from the opposition to the conjunction; which two intervals are usually six months each and divide the year between them.

Emersion, in physics, the rising of any solid above the surface of a fluid specifically heavier than itself, into which it had been violently immerged or thrust. It is one of the known laws of hydrostatics, that a lighter solid being forced down into a heavier fluid, immediately endeavours to emerge; and that with a force equal to the excess of weight and quantity of the fluid above that of an equal bulk of the solid. Thus, if a solid be immerged in a fluid of double its specific gravity, it will emerge again till half its bulk or body be above the surface of the fluid.

E'MERODS, *n. s.* } Corrupted in pronun-
E'meroids. } ciation from hemorrhoids, αιμορροιδες. Painful swellings of the hemorrhoidal veins; piles.

He destroyed them, and smote them with *emerods*. *1 Sam.*

EMERSON (William), a celebrated mathematician, was born in 1701, at Hurworth, near Darlington. In the earlier part of his life he attempted to teach a few scholars; but he soon discontinued the pursuit; and, satisfied with a moderate competence left him by his parents, devoted himself to a studious retirement. Towards the close of 1781 he disposed of the whole of his mathematical library to a bookseller at York; and on May 20th, 1782, died of a lingering and painful disorder at his native village, aged eighty-one. Mr. Emerson was a recluse of singular habits and temper; coarse, proud, and affecting frivolous singularities. To his mathematical acquirements he added considerable skill in the science of music, but was a poor performer. He wrote, 1. The Doctrine of Fluxions; 2. The Projection of the Sphere, orthographic, stereographic, and gnomonical; 3. The Elements of Trigonometry; 4. The Principles of Mechanics; 5. A Treatise of Navigation on the Seas; 6. A Treatise of Algebra, in two books; 7. The Arithmetic of Infinites, and the differential method, illustrated by examples; 8. Mechanics, or the Doctrine of Motion; 9. The elements of Optics, in four books; 10. A System of Astronomy; 11. The Laws of Centripetal and Centrifugal Force; 12. The Mathematical Principles of Geography; 13. Cyclomathesis; or an easy Introduction to the several branches of Mathematics; 14. A short Comment on Sir Isaac Newton's Principia; to which is added, A Defence of Sir Isaac against the Objections that have been made to several parts of his Works.

EMERY, a sub-species of rhomboidal corundum. Its color is intermediate between grayish-black and bluish-gray. It occurs massive and disseminated, and also in granular concretions. Lustre glittering and adamantine. Fracture fine-grained uneven. Translucent on the edges. So very hard as to scratch topaz. Specific gravity 4·0. Its constituents are 86 alumina, 3 silica, 4 iron, and 7 loss. In Saxony it occurs in beds of talc and steatite. It occurs abundantly in the Isle of Naxos, and also at Smyrna. It is used for polishing hard minerals and metals Its fine powder is obtained by trituration and

elutriation. It is also sometimes very red, and then usually contains veins of gold. Dr. Lewis supposes that some kinds of emery may contain platina. For its use in various manufactures, emery is ground in mills, and the powder separated into parcels of different degrees of fineness by washing; distinguished into first, second, and third qualities: the first being that which remains longest suspended in water, the others, such as sink sooner in the same liquor, which is poured from them, with the finer kind swimming in it and afterwards allowed to settle. Emery thus prepared is of great use to different artificers in polishing and burnishing iron and steel works, marble, cutting and scalloping glass, &c.

EMERY (John), an actor of eminence, was born at Sunderland, in the palatinate of Durham, Dec. 22, 1777, and educated at Ecclesfield in Yorkshire, where he acquired that knowledge of the provincial dialect which afterwards contributed so much to his celebrity. In the unsophisticated rustic or the stupid dolt he was excellent; while in some parts, written purposely for him, such as Tyke in the School of Reform, and Giles in the Miller's Maid, his acting was truly terrific and appalling. The portraying of rough nature, fine simplicity, and strong passion, was his forte. In private life he was much esteemed; he died in January, 1822.

EMET'IC, *n. s.*
EMET'ICAL, *adj.*
EMET'ICALLY, *adv.*
Gr. εμετικος, from the verb εμεω, to throw forth; to vomit. A medicine provoking vomits.

EMETICS. See MEDICINE. Emetics may be arranged under those derived from the vegetable, and those from the mineral kingdom. From the vegetable kingdom are numbered ipecacuanha, scilla maritima, anthemis nobilis, sinapis alba, asarum Europæum, nicotiana tabacum. From the mineral kingdom, antimony, the sulphates of zinc and copper, and the subacetate of copper. To these may be added ammonia, its hydro-sulphuret, and the tartar emetic. The preparations of mercury are seldom employed as emetics. The sulphate, or turpeth mineral, has been chiefly used, but its operation is violent.

EMETIN, in chemistry, the vegetable basis of ipecacuan root which is thus procured. Digest ipecacuan root, first in ether and then in alcohol. Evaporate the alcoholic infusion to dryness, redissolve in water, and drop in acetate of lead. Wash the precipitate, and then, diffusing it in water, decompose by a current of sulphureted hydrogen gas. Sulphuret of lead falls to the bottom, and the emetin remains in solution. By evaporating the water this substance is obtained pure.

Emetin forms transparent brownish-red scales. It has no smell, but a bitter acrid taste. At a heat somewhat above that of boiling water, it is resolved into carbonic acid, oil, and vinegar. It is soluble both in water and alcohol. It is precipitated by protonitrate of mercury and corrosive sublimate. Half a grain of emetin acts as a powerful emetic, followed by sleep; six grains vomit violently, and produce stupor and death.

EMICA'TION, *n. s.* Lat. *emicatio*. Sparkling; flying off in small particles, as sprightly liquors.

Iron, in aqua fortis, will fall into ebullition, with noise and *emication*, as also a crass and fumid exhalation. *Browne.*

EMIC'TION, *n. s.* From Latin, *emictum*. Urine; what is voided by the urinary passages.

Gravel and stone grind away the flesh, and effuse the blood apparent in a sanguine *emiction*. *Harvey on Consumptions.*

EM'IGRATE, *v. a.* & *adj.*
EM'IGRANT, *n. s*
EM'IGRATION.
Latin, *emigro*, from *e* & *migro*, to wander. To remove from a place; generally applied to removing from one country to another. An emigrant is he who thus removes.

We find the originals of many kingdoms either by victories, or by *emigrations*, or intestine commotions. *Hale.*

These *emigrants* were to receive pay and subsistence for some years at the public expense. *Robertson.*

The gnats of this country are produced in greater numbers in some years than others, and are then seen in swarms for many evenings near the lakes or rivers whence they arise; and, I suppose, *emigrate* to upland situations, where fewer of them are produced. *Darwin.*

EMIGRATION. This is a topic connected with another very important branch of political economy, that of POPULATION, upon which we are not disposed to express all our opinions until we can support them with that degree of proof of which we consider them to be capable. At present we assume the popular basis of this interesting subject, that population, in all the settled countries of Europe, presses hard upon the means of subsistence; so hard that, with all the local attachments and sympathies of mankind, thousands at this moment are seeking in our own country, the most eligible mode of leaving it for distant shores, and hoping to find, in the cultivation of the very wilds of nature, more of certain subsistence and ultimate comfort, than in their native and still beloved country.

But is this, in itself, an evil? We mean, the propensity of mankind to jostle one another (we know of no equally intelligible mode of expressing what we would convey) in old countries; and thus producing by re-action the exploration and settlement of new ones? We think not. While it may arise immediately from some errors that are reproachful to human nature and human governments, it may also be a part of the wise dispensations of Providence to accomplish the further peopling of the earth, and the more extended happiness of man.

We therefore regard emigration as among the best of expedients in the hands of a *wise government*, for correcting the ordinary surplusage of population; and we would, with all deference, submit that the discreet application of such an expedient, in a country like our own, is peculiarly called for at the present time. What others have regarded as 'a great and radical evil,' afflicting society with 'the want of food,' we would endeavour to exhibit as a principle of expansive good, designed to stimulate the rulers of a country to more enlarged ideas of the government of it; particularly as designed to teach the science of governing such a country

as our own in *times of peace*: and ultimately to impress upon us this great truth, that mankind at large, to be governed happily, must and will finally be governed but as the various branches of one universal family.

We reason in this way, with regard to mankind, considered as a whole. The thinly-peopled parts of the earth have always hitherto been more in number and wider in extent than what are called the thickly-peopled parts. If you have one China, for instance, upon the earth, you have a Russia, and a Turkey in Europe and in Asia, over the face of which all the existing inhabitants of China might be distributed, and travellers in half a century would scarcely perceive a difference in those statistical and moral wastes. At home, if we have one Ireland we have two Canadas (to say nothing of other promising appendages of our empire); and, if these hints of what might be done by way of equalising population and subsistence, be thought speculative, look, we say, at an *accomplished* and matter-of-fact proof, that where any sufficient portion of mankind is duly regarded as one family, they will always find a portion of the one earth we inhabit, abundantly sufficient to maintain them. Look at *our children*, the United States of North America. We were of one family: some of our children we persecuted for their religion, and they went thither; others of them were discontented, or behaved ill at home, and they followed, or were sent after them; at last a general family quarrel took place between the mother country and these distant establishments, and they have now therefore settled themselves as an independent family. But still neither they nor we can blot out *the fact* from history (why should either wish to do it?) that they were and *are* our children; and if we could for a moment admit that we were at this time a decayed and exhausted people at home, we should insist that these new and rising states of the west present an indubitable proof that those parts of the earth which Providence has placed under one control are wide enough for one family. Looking at them and ourselves as branches but of one system of public polity, they are multiplying faster than was ever *recorded* in history, while they are receiving annually large accessions of population from our shores, and those of Europe generally; and have as yet not explored several thousands of miles of the geographical territory they claim, and are capable of defending. We might further advert to old and decayed Spain—ready and worthy to perish as a nation, on one side of the Atlantic, and Mexico, Peru, Colombia, and the central states of America, her children, on the other: or to Portugal, whence, in point of fact, the king and government have emigrated before the people (and they are not likely to have preferred the worse country) on the right hand and Brasil on the left. If all this has been done, we say, with the earth, in our own time and memory almost, when mankind have been almost universally quarrelling, and much of it in direct connexion with these quarrels, what might not be done if men could learn to agree?

In fact, upon this subject, we must be allowed to quote an anecdote of the life of the late bishop Watson. Being told of the tendency and general arguments of a certain celebrated work on the alarming increase of our population: 'I laid it down,' he says, 'for even admitting his theory that population has a tendency to increase in particular circumstances beyond the means of subsistence; as God and nature *say*, 'Increase,' it is our clear and indisputable duty not to attempt to stop the one, but TO AUGMENT THE OTHER.' We contend, therefore, that the history and experience of the last two centuries, go to prove that the resources of mankind, considered as a whole, are *unbounded by any calculation* we can make, or that is ever likely to become practicable; or that our duty to our own people, and those of all other countries, as far as we have power, is not to check population, but to increase the means and happiness of our fellow-men: we cannot check population in the virtuous and 'honorable' method in which God has appointed it to increase, without increasing vice, and with vice, misery. While we cannot earnestly desire and industriously endeavour to promote and economise the means and happiness of mankind, without increasing virtue, teaching and practising religion in its best forms; leading others, and being led ourselves, from suffering man to a wise and benevolent God.

It will not here be out of place to review briefly what the modern investigation of the doctrine of population seems to have established.

1. Then it would appear to be proved by the united evidence of ancient history and recent discovery; it is forced upon our belief by all that we hear, or read, or see, or feel; that it is the uniform tendency of population in every known stage of society, from the earliest to the most advanced, to press against the actual or available supply of food.

2. Population, even while it presses against the existing provision of subsistence, has a uniform tendency to keep within the powers of the soil, if the natural order of things is not counteracted by human neglect or impolicy. Because before the productive powers of any tolerably fertile soil can be nearly exhausted, the people in the regular progress of social communities must have become colonial, commercial, manufacturing; must be collected into large towns and cities; must require soldiers, mariners, servants, &c.; in short, must have reached that state of society in which population does not increase with rapidity.

3. During the alternate progress of population and subsistence, the pressure of the former by a previous increase of people is necessary to stimulate the community to a further production of food: so that the pressure of population against the means of subsistence, instead of being the cause of most of the miseries of human life, is in well-governed states the cause of all public happiness, industry, and prosperity. The pressure against subsistence ensures industry, industry ensures increase of produce, increase of produce again encourages population; and these alternate oscillations of the balance are calculated not to disjoin, but to unite and strengthen the structure of society. If with this

last view of the beneficial effects of the principle of population as inherent in our nature, we connect the indubitable facts of the large colonies that accrue to all extensively civilised and commercial people; and the existing state and capabilities of our own country in this respect, before alluded to, the modern doctrine of population, admitting all its facts with regard to rapid increase, stimulates us to gratitude and exertion, not to alarm and despair.

It should stimulate us to avail ourselves of our colonies: to regard the whole territorial dominions of Great Britain and its dependencies as one integral government, one common soil. Let the government so regard it; and, removing all foreign and inequitable laws in the colonies, and approximating them as much as possible to the institution of the mother country in their entire condition, encourage respectable, and give facilities of removal to poorer emigrants. In fact, so complete an illustration of our views of this important topic is presented in the existing situation of Ireland on the one hand, and our dominions in North America on the other, that we shall content ourselves in this paper with abridging a luminous statement of the facts on this subject which has lately appeared in the Edinburgh Review.

Ireland then, at this moment (1827), has an alarming portion of its people *habitually* involved in the most squalid and abject poverty. The witnesses examined by the late committees of the houses of lords and commons on the state of Ireland, all concur in representing the population as excessive, and the condition of the poor as wretched in the extreme. Above 6,000,000 of peasantry are hutted over the face of the country. Their cabins are not superior, perhaps not equal, to the wigwams of the American Indians; they are destitute of chimneys, and of any thing that can be called furniture; many families are without either beds or bed-clothes; the children, generally in rags, are often absolutely naked; and, whenever the potatoe crop becomes even in a slight degree deficient, which is found to be the case once every five or six years, the scourge of famine and disease is felt in every corner of the country! Mr. Maurice Fitzgerald, M. P., informed the committee on the Employment of the Irish Poor, that 'he had known the peasantry of Kerry quit their houses in search of employment, offering to work for the merest subsistence that could be obtained, for two-pence a day, in short for any thing that would purchase food enough to keep them alive for the next twenty-four hours.' Mr. Tighe mentions, that 'the number of persons in Ireland supported by charity is quite inconceivable; they must be supported either by charity, or by pillage and plunder; to the want of employment I attribute every thing that afflicts and disgraces the country.' (Report p. 153.) 'In the part of the country (Cork) with which I am best acquainted,' says Mr. O'Drischoll, 'the condition of the people is the very worst that can possibly be; nothing can be worse than the condition of the lower classes of laborers, and the farmers are not much better. The land is overpeopled and exhausted.' (Report on the State of Ireland, p. 380) Dr. Rogan, a physician of eminence, employed by government to report on the state of disease in the north of Ireland, states, in his valuable work on the Fever in Ulster, that 'throughout the extensive counties of Tyrone, Donegall, and Derry, the population is only limited by the difficulty of procuring food. Owing to the universal adoption of the cottier system, and to the custom of dividing farms among sons at the death of the father, the laboring classes are infinitely more numerous than are required for the purposes of industry. Under these circumstances, they are engaged in a constant struggle for the bare necessaries of life, and never enjoy its comforts,' (p. 8). And, not unnecessarily to multiply references, we shall only further subjoin the following extract from the evidence of Dr. Doyle, the catholic bishop of Leighlin. 'The population is immediately increased, as every one must perceive, by improvident marriages; but those marriages themselves, in my opinion, result in a great measure from the extreme poverty of the people; for that poverty has paralyzed their energies; it has prevented them from taking such an interest in creating a respectable situation for themselves in life, as men possessed of some property always feel; for those wretched people say their state cannot be worse when married than before, and hence they go together. Their depression throws them together, like savages in a wood. It is a frightful state of society; and, when it is considered, it fills me with so much pain and horror, that I have frequently prayed to God, if it were his will, rather to take me out of life than to leave me to witness such evils.' (Report, p. 208).

Statements to the same effect might be produced from other quarters: but the obvious and pressing question is, What is to become of the wretches who are thus situated? They can obtain no employment in the towns, which are already gorged with unemployed inhabitants: and it is therefore quite evident, that if they are not carried to some other country, or in some way provided for, the landlords will either not be able to continue the system they have begun, and the reign of pauperism and degradation will in consequence be perpetuated, or the ejected paupers will transport themselves to Great Britain, and lay the foundations of the same wretchedness here that is now universal in their own country. It is thus clear, that, in whatever point of view this subject may be considered, it is of paramount importance to the people of Britain. But we need not reason hypothetically on the subject. The process of equalisation has already commenced. 'We believe that it is not too much to say,' observes the Edinburgh Review, No. 89, 'that at this moment from a fourth to a third part of the laborers in the west of Scotland and the west of England consist of Irishmen. The latter have almost entirely supplanted the Scotch and English laborers in all those departments in which strength is of more importance than skill; and they are rapidly gaining on them in the others. The consequence is, that a double injury is inflicted upon the native population of Britain. In the first place, their wages are reduced by the competition of the Irish; and, in the second place, their opinions with respect to what is neces-

sary for their comfortable and decent subsistence, are lowered by the contaminating influence of example, and by familiar intercourse with those who are content to vegetate in filth and misery. Previously to the increased facilities of conveyance afforded by means of steam navigation, the expense of the passage from Ireland to Britain, trifling as it was even then, formed a serious obstacle to the influx of Irish poor. But this expense has now been reduced to almost nothing; and it consists with our knowledge, that thousands of poor creatures have been landed from the steam-packets at Liverpool and Greenock within these two years, the cost of whose conveyance from Ireland did not exceed from 4*d*. to 6*d*. each!'

The member for Glasgow, Mr. Campbell, informed the committee of the house of commons, that he had good reason to think, from the reports of well-informed gentlemen, that there are at present not less than 40,000 Irish established in Glasgow and its immediate vicinity. And the gentlemen of Lanarkshire have, in a report on the state of the county, which they transmitted to government on the 23d of September last, particularly called the attention of ministers to this circumstance. They state, that the want of employment, so severely felt at present by the laborers and tradesmen of Glasgow, Paisley, &c., has been greatly aggravated by the continued influx of Irish paupers, who can bear almost every sort of privation; and they farther state, that the natives of the country are endeavouring to escape from their competition, by emigrating in great numbers to America, leaving their places to be occupied by the half-famished hordes that are daily pouring in.

Such are the crying evils and calamities which peremptorily call for attention on the one hand. Government has been engaged, we are happy to find, in investigating them patiently: as also in considering the kind of remedy likely to be afforded by a judicious plan of emigration on the other. The report of a select committee of the house of commons on emigration, which was printed in May last, distinctly recommends assisting the transmission of the Irish poor in considerable numbers to our North American dominions: and the Edinburgh Review wisely presses its being attempted on an adequate scale.

Mr. Bowman Felton, one of the legislative counsellors of the province of Lower Canada, states that it could support 6,000,000 of wheat consumers: at present it does not contain above 460,000 inhabitants. And though there are disadvantages incident to extensive districts, from want of markets, and the injudicious mode in which the lots already occupied have been laid out, there can, at all events, be no doubt that, were it necessary, from 300,000 to 400,000 emigrants might be advantageously located there.

Upper Canada has a noble range of country, which stretches from Lake Simcoe and the rivers Trent and Severn westward, to Lake Huron and the St. Clair River, and southward to Lake Erie, and part of Lake Ontario, with an unoccupied soil of extraordinary fertility, capable of producing the most luxuriant crops of grain. 'The climate,' says Mr. Bouchette, surveyor-general of Lower Canada, 'is so particularly salubrious, that epidemic diseases, either among men or cattle, are almost entirely unknown. Its influence upon the fertility of the soil is more generally perceptible than it is in Lower Canada, and is supposed to be congenial to vegetation in a much superior degree. The winters are shorter, and not always marked with such rigor as in the latter. The duration of the frost is always accompanied with a fine clear sky, and a dry atmosphere. The spring opens, and the resumption of agricultural labors takes place from six weeks to two months earlier than in the neighbourhood of Quebec. The summer heats rarely prevail to excess, and the autumns are usually very friendly to the harvests, and favorable for securing all the late crops.' The ground on the shores of lake Ontario and lake Erie, as far west as the junction of the Thames with the St. Clair Lake, is laid out in townships, and partly settled. But the population is so very thin, as not, on an average, to amount to more than sixteen persons to a square mile in the settled townships; while the fertility of the soil is such, that 120 persons to a square mile would not be a dense population. To the north of the river Thames, along the banks of the river St. Clair, and the shores of lake Huron, round to the river Severn, and from thence to the river that joins Lake Nippissing and Lake Huron, is a boundless extent of country that is entirely unoccupied. The interior of this space has hitherto been but imperfectly explored; but the banks of the St. Clair and the shores of Lake Huron afford the finest situations for settlements. The soil is, in many places, of the greatest fertility, the rivers and lakes teem with fish, and every variety of the best timber is found in the greatest profusion. In 1783 the settlers in Upper Canada were estimated at only 10,000. In 1820 they amounted, according to Mr. Gourlay, to upwards of 134,000; and may now probably amount to nearly 200,000—a miserably small population for a country that could comfortably support many millions of inhabitants.

In Nova Scotia and New Brunswick the winter is more severe than in Upper Canada, and they are a good deal infested with fogs and mists. But their greater proximity to England, and their favorable situation for the fishing business, give them also great advantages.

With regard to the probable expense of this procedure, it has been ascertained that emigrations to Canada were conducted from Glasgow and its neighbourhood in 1821, by a committee of management, at the rate of £2 18*s*. per head, including provisions, which were then low. Any number, it is supposed, might be transferred from Scotland to Quebec at the present time for £3 5*s*. or £3 10*s*. per head, making ample provision for contingencies. From Ireland it has been calculated that emigrants might be conveyed to lots of profitable land in Lower Canada from £4 to £4 10*s*. all expenses included.

On the whole, therefore, we are disposed to think, says the able writer we have already quoted, that the expenses consequent upon the transportation of 1,000,000 of emigrants from Ireland to America, and disposing of them there, might be fairly estimated as under, viz.

| | |
|---|---|
| Expense of conveying 33,000 emigrants to Cape Breton, and establishing them there (passage out and internal conveyance £3 5*s*., establishment £10 10*s*.), £13 15*s*. each . . . . . . | £454,000 |
| Expense of conveying 133,000 emigrants to Nova Scotia, &c. (passage, &c. £3 10*s*., establishment £10 10*s*.) £14 each . . . | 1,862,000 |
| Expense of conveying 350,000 emigrants to America, and furnishing them with a little money, £8 8*s*. each . . . . . . | 2,940,000 |
| Expense of conveying 484,000 emigrants to Lower and Upper Canada and establishing them there (passage, &c. £5 5*s*., establishment £12 10*s*.), £17 15*s*. each . | 8,591,000 |
| Total expense of conveying 1,000,000 of emigrants to America, and establishing them there . . | £13,847,000 |

'This is undoubtedly a very considerable sum; but, considerable as it is, we have no hesitation in saying that, though it were twice as great, it would be well and advantageously laid out in securing the object in view. Look at the alternative under which this question is placed. If, on the one hand, we incur the expense consequent upon the prosecution of emigration on the large scale we have proposed, we shall relieve Ireland of the surplus population by which she is now oppressed and beggared, and shall enable means to be adopted for securing her future and rapid improvement, at the same time that we shall protect and secure our own population from being overrun and degraded by the influx of Irish poor: but if, on the other hand, we refuse to incur this expense, and allow matters to remain on their present footing, it is idle to talk of the improvement of Ireland: her misery will be rendered perpetual; and every year thousands of starving wretches will be cast upon our shores, till our people have been sunk, in consequence of their influx, to the same level of hopeless misery as the Irish, and the scourge of universal mendicity has avenged centuries of misgovernment!'

We must finally be allowed to quote Mr. Malthus himself as arguing for the necessity of occasional emigration.

'If,' says he, in 1817, 'from a combination of external and internal causes, a very great stimulus should be given to the population of a country for ten or twelve years together, and it should then comparatively cease, it is clear that labor will continue flowing into the market, with almost undiminished rapidity, while the means of employing and paying it have been essentially contracted. It is precisely under these circumstances that emigration is most useful as a temporary relief; and it is in these circumstances that Great Britain finds herself placed at present. Though no emigration should take place, the population will by degrees conform itself to the state of the demand for labor; but the interval must be marked by the most severe distress, the amount of which can scarcely be reduced by any human efforts; because, though it may be mitigated at particular periods, and as it affects particular classes, it will be proportionably extended over a larger space of time and a greater number of people. The only real relief in such a case is emigration; and the subject at the present moment is well worthy the attention of the government, both as a matter of humanity and policy.' —*On Population*, vol. ii. pp. 304, 305.

Return of the number of persons who have emigrated from Great Britain and Ireland to the British colonies and to the United States of America, in each year from 1825 to the 31st of December, 1832, distinguishing the ports from which they have sailed, and the countries to which such emigration took place:—

| | 1825. | 1826. | 1827. | 1828. | 1829. | 1830. | 1831. | 1832. |
|---|---|---|---|---|---|---|---|---|
| To the British Colonies in America . . . . | 8,741 | 12,818 | 12,648 | 12,084 | 13,307 | 30,574 | 58,067 | 66,339 |
| To the Cape of Good Hope | 114 | 116 | 114 | 135 | 197 | 204 | 114 | 196 |
| To the Australian Colonies | 485 | 903 | 715 | 1,056 | 2,016 | 1,242 | 1,561 | 3,733 |
| To the United States . | 5,551 | 7,063 | 14,526 | 12,817 | 15,678 | 24,887 | 23,418 | 32,872 |
| Total . . . . | 14,891 | 20,900 | 28,003 | 26,092 | 31,198 | 56,907 | 83,160 | 103,140 |

EMIMS, ancient inhabitants of the land of Canaan beyond Jordan, towards the Dead Sea; who were defeated by Chedorlaomer and his allies. Moses tells us (Gen. xiv. 5) that they were beaten in Shaveh Kirjathaim; which was in the country of Sihon conquered from the Moabites. Josh. xiii. 19—21. The Emims were a warlike people, of a gigantic stature, and very numerous. The Moabites cut off most of them, and incorporated with the rest, when they seized their country. Deut. ii. 10, 11.

EM'INENCE, *n. s.* Fr. *eminent*; Italian,
EM'INENCY, Span. and Port. *emi-*
EM'INENT, *adj.* *nente*; Lat. *eminens*, from
EM'INENTLY, *adv.* *e* out, and *maneo*; Gr. *μενω*, to stand. Loftiness of place, or station; conspicuousness: eminence is also a title applied particularly to the Romish cardinals.

Thou hast built unto thee an *eminent* place.
*Ezekiel.*

These two were men of *eminency*, of learning as well as piety. *Stillingfleet.*

Censure is the tax a man pays to the public for being *eminent*. *Swift.*

First let the Kennel be the huntsman's care,
Upon some little *eminence* erect,
And fronting to the ruddy dawn. *Somerville.*

Whosoever shall look heedfully upon those who are *eminent* for their riches, will not think their condition such as that he should hazard his quiet, and much less his virtue, to obtain it. *Johnson.*

I was once told by a great master that no man ever excelled in painting, who was *eminently* curious about pencils and colours. *Id.*

As his own *eminence* was founded upon the power of the church of Rome, he was a zealous defender of that superstition. *Robertson. History of Scotland.*

There is no one particular that I know of wherein self-knowledge more *eminently* consists, than it does in this. *Mason.*

The road to *eminence* and power from obscure condition, ought not to be made too easy, nor a thing too much of course. If rare merit be the rarest of all rare things, it ought to pass through some sort of probation. The temple of honour ought to be seated on an *eminence*. If it be open through virtue, let it be remembered too, that virtue is never tried but by some difficulty and some struggle. *Burke.*

Strange, that such folly, as lifts bloated man
To *eminence* fit only for a god,
Should ever drivel out of human lips,
Even in the cradled weakness of the world!
*Cowper.*

Ye cherub train, that brought him on his way,
O leave him not 'midst tumult and dismay;
For now youth's *eminence* he gains:
But what a weary length of lingering toil remains!
*Beattie.*

EMINENCE, an honorary title. The decree of pope Urban VII., appointing that the cardinals should be addressed by this title is dated January 10th, 1630. They then laid aside the titles of illustrissimi, and reverendissimi, which they had borne before. The ci-devant grand master of Malta was likewise addressed under the quality of eminence. Popes John VIII., and Gregory VII., gave this title to the kings of France. The emperors have likewise borne it.

EMIR, a title of dignity among the Turks, signifying a prince. This title was first given to the caliphs; but, when they assumed the title of sultans, that of emir remained to their children; as that of Cæsar among the Romans. At length the title was awarded to all who were descended from Mahomet by his daughter Fatimah, and who wear the green turban instead of the white. The Turks also call the viziers, bashaws, or governors of provinces, by this title.

EMIT', *v. a.* } Lat. *emitto*, from *e* forth and
EM'ISSARY, } *mitto*; Gr. μεθιω; Chald. משא
EMIS'SION. } to send. To send forth, issue or give out; eject: an emissary is one sent forth; also in a technical sense one that emits or sends out.

Tickling causeth laughter: the cause may be the *emission* of the spirits, and so of the breath by a flight from titillation. *Bacon.*

Clifford, an *emissary* and spy of the king's, fled over into Flanders with his privity. *Bacon's Henry VII.*

You shall neither eat nor sleep,
No, nor forth your window peep,
With your *emissary* eye,
To fetch in the forms go by.
*Ben Jonson's Underw.*

Populosity naturally requireth transmigration and *emission* of colonies. *Browne's Vulgar Errours.*

Cover them with glasses; but upon all warm and benign *emissions* of the sun, and sweet showers, give them air. *Evelyn.*

Affection, in the state of innocence, was happily pitched upon its right object; it flamed up in direct fervours of devotion to God, and in collateral *emissions* of charity to its neighbour. *South.*

Pay sacred reverence to Apollo's song,
Lest wrathful, the far-shooting god *emit*
His fatal arrows. *Prior.*

These baths continually *emit* a manifest and very sensible heat; nay, some of them, at some times, send forth an actual and visible flame. *Woodward's Natural History.*

The soil, being fruitful and rich, *emits* steams, consisting of volatile and active parts. *Arbuthnot on Air.*

Wherever there are *emissaries*, there are absorbent vessels in the skin; and, by the absorbent vessels, mercury will pass into the blood. *Id. On Aliments.*

That a citation be valid, it ought to be decreed and *emitted* by the judge's authority, and at the instance of the party. *Ayliffe.*

The Jesuits send over *emissaries*, with instructions to personate themselves members of the several sects among us. *Swift.*

In some lime-stones the living animals seem to have been buried as well as their shells during some great convulsion of nature; these shells contain a black coaly substance within them, in others some phlogiston or volatile alkali from the bodies of the dead animals remains mixed with the stone, which is then called liver-stone as it *emits* a sulphurous smell on being struck. *Darwin.*

Water in descending down elevated situations, if the outlet for it below is not sufficient for its *emission*, acts with a force equal to the height of the column, as is seen in an experimental machine called the philosophical bellows, in which a few pints of water are made to raise many hundred pounds. *Id.*

EMLYN (Thomas), a Unitarian minister, born at Stamford in Lincolnshire, in 1663. After receiving a preparatory education, he became chaplain to the countess of Donegal, a dissenter, whom he accompanied to Ireland. In 1683 he returned to England, and was chosen minister of a congregation at Lowestoff. In 1691 he removed to Dublin, at the invitation of Mr. Boyce, to be his assistant; but venturing to preach Arian doctrines the Dublin synod suspended him from the ministry; on which he wrote a book entitled, An humble Enquiry into the Scripture Account of Jesus Christ. For this, a prosecution was instituted against him, and, the jury having found him guilty of blasphemy, he was sentenced to pay a fine of £1000 and to suffer one year's imprisonment. The fine was afterwards commuted for £70, but he remained two years in confinement. After his release he went to London, where he officiated to a small congregation for a few years. He died in 1743. Besides the above work, he wrote, 1. Tracts on Socinianism; 2. Vindication of the Worship of the Lord Jesus Christ, on Unitarian principles, 8vo.; 3. The supreme Deity of God the Father demonstrated;

4. A Treatise on Baptism; 5. Inquiry into the original authority of 1 John v. 7, &c.

EMMA, daughter of Richard II., duke of Normandy, and mother of Edward the Confessor, king of England. She was first married to Ethelred, who was obliged to go to Normandy with his sons Alfred and Edward, upon the invasion of the kingdom by the Danes. After his death she married Canute. See ENGLAND. During the reign of her son, the earl of Kent accused her of an improper intercourse with her relation, the bishop of Winchester, on which, to prove her innocence, she is said to have walked barefoot over burning ploughshares, without being hurt.

EMMERICH, a neat town of Prussia, situated in a fruitful plain on the right bank of the Rhine. Population 4000. Five miles north-east of Cleves.

EM'MET, *n. s.* Sax. æmette; Belg. *emte*; Teut. *ameise*, from the Sax. verb ametan to provide. Another name for the ant. See ANT.

EMMET (Thomas Addis), an eminent Irish lawyer and patriot, was born in the city of Cork, in Ireland, in 1765. He was placed at the university of Dublin, where he obtained an *optimè*, was designed for the profession of medicine, and pursued his medical studies at Edinburgh. The death of his elder brother, a member of the Irish bar, induced him to pass to the study of the law. He went to London, read two years in the Temple, and attended the courts at Westminster. On his return to Dublin he commenced practice, and soon obtained distinction and business. The celebrated Curran was one of his circuit and term companions. Being of an ardent character, and enthusiastically Irish, he early imbibed an antipathy against British connexion. When the societies of united Irishmen were revived in the year 1795, Emmet joined the association, and soon became a leader. Their object was revolution, and an independent government for Ireland. Emmet acted as one of the grand executive committee of the societies, who consisted of at least 500,000 men. March 12, 1798, he was arrested, and committed to prison at Dublin, as a conspirator, by the vice-regal government, along with Oliver Bond, doctor Macneven, and other chiefs of the disaffected party. In July, after a severe confinement, an interview took place beetween Emmet and lord Castlereagh, at Dublin castle, and it was agreed that he and the other state prisoners should be permitted to go to the United States, as soon as they had disclosed their plans of revolution, and the projected alliance between the united Irishmen and France. These disclosures were made in a memoir, delivered August 4, but without the confession of any names, which were inflexibly refused by the writers. They were, soon after, examined in person before the secret committees of both houses of the Irish parliament. Instead, however, of being sent to the United States, Emmet and nineteen more were, early in 1799, landed in Scotland, and consigned to fort George, a fortress in the county of Nairn. Here they were liberally treated, but their detention lasted three years. At the expiration of that period, the list of pardons arrived, including the name of every prisoner except Emmet. The governor of the fortress released him, notwithstanding, taking all the responsibility. Emmet, and his exemplary wife, who had shared unremittingly his imprisonment, both in Ireland and Scotland, were landed at Cuxhaven from a British frigate, spent the winter of 1802 in Brussels, and that of 1803 in Paris. In October, 1804, they sailed from Bordeaux for the United States, and arrived in New York on the 11th of the next month. Emmet, then about forty years of age, at first hesitated between the professions of the law and medicine; but his friends determined him to undertake the former. George Clinton, then governor of the state of New York, induced him to abandon his original plan of settling in Ohio, and to remain in the city of New York. He was admitted to the bar at once, by special dispensation, and reached the first ranks of the profession in a short time, by indefatigable industry and fervid eloquence. In the course of a few years he rivalled in business and fame the most eminent of the American lawyers. Occasionally the ardour of his temperament and the vivacity of his recollections betrayed him into party politics, but his general career and character were those of a laborious, able, and most successful pleader, an energetic and florid orator, and a courteous gentleman. In 1812 he was appointed to the office of attorney-general of the state of New York. His death took place in the 63rd year of his age, in a remarkable way, Nov. 14, 1827, while attending the trial of an important cause at New York, in the circuit court of the United States, he was seized with an apoplectic fit, which put an end to his existence the following night. A deserved tribute of public respect was paid to his memory. During his imprisonment at fort George, Emmet wrote an Essay towards a History of Ireland, which was printed at New York in the year 1807.

EMMIUS (Ubbo), a learned professor, born at Gretha, in East Friesland in 1547, and chosen rector of the college of Norden in 1579; from which place he was ejected in 1587, for refusing to subscribe the Confession of Augsburg. In 1588 he was made rector of the college of Leer; and when the city of Groningen confederated with the United Provinces, the magistrates appointed him rector of that college: which employment he filled with the highest reputation for nearly twenty years. The college being erected into a university, he was the first rector. He wrote Vetus Græcia illustrata, 3 vols.; Decades Rerum Frisicarum; and many other valuable works. He died in 1625.

EMOL'LIENT, *n. s.* & *adj.* } Fr. *emollir*; Lat.
EMOLLI'TION, *n. s.* } *emollire*, from *e*, expletive, and *mollis*; Gr. μαλακος soft, from the verb μαλασσω; Heb. מלין to sooth. That which softens, supples or soothes certain parts or solids of the body; the act of softening or suppling.

EMOL'UMENT. Fr. *emolument*; Lat. *emolumentum*, from *molo* to grind; emolument originally signifying the grist gained by the miller for grinding corn, &c.: and hence profit, advantage, remuneration generally.

EMO'TION, *n. s.* Fr. *emotion*, from Latin *emoveo*, *emotus*, *e* and *moveo* to move, rouse, excite. Emotion is vehemence, or its consequence, disturbance of mind.

The first great sub-division, then, which I would form of the internal class, is, into our intellectual states of mind, and our *emotions*. The latter of these classes comprehends all, or nearly all, the mental states, which have been classed by others under the head of active powers. *Dr. T. Brown.*

And when winds are at war with the ocean,
As the breasts I believed in with me,
If their billows excite an *emotion*
It is that they bear me from thee. *Byron.*

EMPALE', *v. a.* Fr. *empaler*, a compound of em and pale. To enclose, fence, or fortify, with pales; also to pierce with a pale or stake.

Round about her work she did *empale*
With a fair border wrought of sundry flowers. *Spenser.*

Keep yourselves in breath,
And when I have the bloody Hector found,
*Empale* him with your weapons round about. *Shakspeare.*

All that dwell near enemies *empale* villages, to save themselves from surprise. *Raleigh's Essays.*

They have *empaled* within a zodiack
The free-born sun, and keep twelve signs awake
To watch his steps; the goat and crab controul
And fright him back. *Donne.*

The English *empaled* themselves with their pikes, and therewith bare off their enemies. *Hayward.*

Impenetrable, *empaled* with circling fire,
Yet unconsumed. *Milton's Paradise Lost.*

Who can bear this, resolve to be *empaled?*
His skin flead off, and roasted yet alive? *Southerne.*

Let them each be broken on the rack;
Then, with what life remains, *empaled* and left
To writhe at leisure round the bloody stake. *Addison.*

Nay, I don't believe they will be contented with hanging; they talk of *empaling*, or breaking on the wheel. *Arbuthnot.*

EMPALEMENT, from in and palus, Lat. a stake, an ancient barbarous punishment, which consisted in thrusting a stake up the fundament. It is mentioned by Juvenal. It was often inflicted under Nero, and continues to be so in Turkey, and in Arabia.

EMPALEMENT OF A FLOWER, the same with calyx.

EM'PANNEL, *v. a.* & *n. s.* From the Fr. *panne*, a piece of parchment on which the names of persons summoned as jurors are written. To summon or form a jury: as a noun it has been used for the list or parchment itself; but panel is the more usual word in modern times.

I shall not need to *empannel* a jury of moralists or divines, every man's own breast sufficiently instructing him. *Government of the Tongue.*

EMPA'RLANCE, *n. s.* From Fr. *parler*, signifieth, in law, says Cowell, a desire or petition in court of a day to pause what is best to do: and it is sometimes used for the conference of a jury in the cause committed to them: in a general sense it means parley.

——Talus forth issuing from the tent,
Unto the wall his way did fearlesse take,
To weeten what that trumpit's sounding ment,
Where that same damzell loudly him bespake,
And shewed that with his lord she would *emparlance*
make. *Spenser. Faerie Queene*

EMPAS'SION, *v. a.* } From em, or en, and pas-
EMPAS'SIONATE, *adj.* } sion. To move or fill with passion: strongly affected or moved.

With the near touch thereof in tender heart,
The Briton prince was sore *empassionate*. *Spenser.*

Unto my eyes strange shows presented were,
Picturing that which I in mind embraced,
That yet those sights *empassion* me full near. *Id.*

So, standing, moving, or to height upgrown,
The tempter, all *empassioned*, thus began. *Milton.*

EMPEDOCLES, a celebrated philosopher and poet, born at Agrigentum, in Sicily. He followed the Pythagorean philosophy, and admitted the metempsychosis. He constantly appeared with a crown of gold on his head. Yet Aristotle says, that he was a great lover of liberty, extremely averse to state and command, and that he even refused a kingdom that was offered him. His principal work was a Treatise, in verse, on the Nature and Principles of Things. Aristotle, Lucretius, and the ancients, make the most magnificent eulogiums on his poetry and eloquence. He taught rhetoric; and often alleviated the anxieties of his mind, as well as the pains of his body, with music. It is reported, that his curiosity to visit the flames of the crater of Ætna proved fatal to him. Some maintain that he wished it to be believed that he was a god; and that his death might be unknown he threw himself into the crater and perished in the flames. His expectations, however, were frustrated; and the volcano, by throwing up one of his sandals, discovered to the world that Empedocles had perished by fire. Others report that he lived to an extreme old age; and that he was drowned in the sea about A.A.C. 440.

EMPE'OPLE, *v. a.* From em and people. To form into a people or community.

He wondered much, and 'gan enquire
What stately building durst so high extend
Her lofty towers unto the starry sphere,
And what unknown nation there *empeopled* were? *Spenser.*

EM'PEROR, *n. s.* } Fr. *empereur*; Span.
EM'PERESS, or } and Port. *emperador*; Ital.
EM'PRESS, } and Lat. *imperator*, from
EM'PERY, } *impero*, to command, i. e.
EM'PIRE. } *in* and *paro*, to make ready or prepare, the first command given to the Roman soldiers previous to marching.—Adams. A high monarchical title. Emperess and empress are its feminines: empery and empire, the authority possessed, or dominion governed by an emperor.

But the iewis crieden and seiden, if thou delyverist this thou art not the *empouris* frend. *Wiclif. Jon.* 19.

Like to an eagle in his kingly pride,
Soring through his wide *empire* of the aire,
To weather his broad sailes. *Spenser. Faerie Queene.*

Sextus Pompeius
Hath given the dare to Cæsar, and commands
The *empire* of the sea. *Shakspeare. Antony and Cleopatra.*

Take on you the charge
And kingly government of this your land,
Not as protector, steward, substitute,

But as successively from blood to blood,
Your right of birth, your empery, your own. *Id.*

Charles the *emperour*,
Under pretence to see the queen his aunt,
Makes visitation. *Id. Henry VIII.*

Lavinia will I make my *emperess*,
Rome's royal mistress, mistress of my heart. *Id.*

Long, long, may you on earth our *empress* reign,
Ere you in heaven a glorious angel stand. *Davies.*

Let your nimble feet
Tread subtile circles, that may always meet
In point to him; and figures, to express
The grace of him, and his great *emperess*. *Ben Jonson.*

They are the moths and scarabs of a state,
The bane of *empires*, and the dregs of courts,
Who to endear themselves to an employment,
Care not whose fame they blast. *Id.*

*Empress* of this fair world, resplendent Eve. *Milton.*

A nation extended over vast tracts of land, and numbers of people, arrives in time at the ancient name of kingdom, or modern of *empire*. *Temple.*

The *emperor* one day took up a pencil which fell from the hand of Titian, who was then drawing his picture; and, upon the compliment which Titian made him on that occasion, he said, Titian deserves to be served by Cæsar. *Dryden.*

Yet, London, *empress* of the northern clime,
By an high fate thou greatly didst expire. *Id.*

Assert, ye fair ones, who in judgment sit,
Your ancient *empire* over love and wit. *Rowe.*

To give pain is the tyranny, to make happy, the true *empire* of beauty. *Steele.*

Wisdom, thou sayest, from heaven received her birth;
Her beams transmitted to the subject earth:
Yet this great *empress* of the human soul,
Does only with imagined power controul,
If restless passion, by rebellious sway,
Compels the weak usurper to obey. *Prior.*

What are riches, *empire*, power,
But larger means to gratify the will?
The steps on which we tread, to rise and reach
Our wish. *Congreve.*

The pride of nature would as soon admit
Competitors in *empire* as in wit;
Onward they rush at Fame's imperious call,
And less than greatest would not be at all. *Churchill.*

I am provoked at the contempt which most historians show for humanity in general: one would think by them that the whole human species consisted but of about 150 people, called and dignified (commonly very undeservedly too) by the titles of *emperors*, kings, popes, generals, and ministers. *Chesterfield.*

An *emperor* in his night-cap would not meet with half the respect of an *emperor* with a crown. *Goldsmith.*

It became the common belief, that a prince would arise at that time in Judea, who would change the face of the world, and extend his *empire* from one end of the earth to the other. *Robertson's Sermons.*

Mourn him, thou Sun, great source of light!
Mourn, *empress* of the silent night!
And you, ye twinkling starnies bright,
My Matthew mourn!
For through your orbs he's ta'en his flight,
Ne'er to return. *Burns.*

Taking in the whole view of life, it is more safe to live under the jurisdiction of severe but steady reason, than under the *empire* of indulgent, but capricious passion. *Burke.*

Folly such as yours,
Graced with a sword, and worthier of a fan,
Has made, what enemies could ne'er have done,
Our arch of *empire*, steadfast but for you,
A mutilated structure, soon to fall. *Cowper.*

Whence Reason's *empire* o'er the world presides,
And man from brute, and man from man divides;
Compares and measures by imagined lines
Ellipses, circles, tangents, angles, sines. *Darwin.*

Fallen are the trophies of Assyrian power,
And Persia's proud dominion is no more;
Yea, though to both superior far in fame,
Thine empire, Latium, is an empty name. *Beattie.*

The great extent of the Roman empire was one chief cause of that despotism which came at last to prevail in it. *Id.*

EMPEROR, among the ancient Romans, signified a general of an army, who, for some extraordinary success, had been complimented with this appellation. Thus Augustus, having obtained no less than twenty victories, was as often saluted with the title emperor; and Titus was denominated emperor by his army after the reduction of Jerusalem. Afterwards, it came to denominate an absolute monarch or supreme commander of an empire. In this sense Julius Cæsar was called emperor: the same title descended with the dignity to Octavius, Tiberius, and Caligula; and afterwards it became elective. The title emperor does not, and cannot, add any thing to the rights of sovereignty: its effect has only been to give precedence and pre-eminence above other sovereigns. It has been sometimes disputed, if emperors have the power of disposing of the regal title. They have certainly sometimes taken upon them to erect kingdoms: thus Bohemia and Poland are said to have been raised to that dignity: thus also, the emperor Charles II. in 877, gave Provence to Boson, putting the diadem on his head, and decreeing him to be called king, ut more priscorum imperatorum regibus videretur dominari. And the emperor Leopold erected ducal Prussia into a kingdom in favor of the elector of Brandenburg; though several of the kings of Europe refused to acknowledge him in that capacity, until the treaty of Utrecht in 1712. In the east, the title and quality of emperor are more frequent than among us: thus, the sovereign princes of China, Japan, Mogul, Persia, &c., have been called emperors. In 1723 the czar of Muscovy assumed the title of emperor of all the Russias, and procured himself to be recognized as such by the princes and states of Europe. In the west, the title was long restrained to the emperors of Germany. The first who bore it was Charlemagne, who had it conferred upon him by pope Leo III. having indeed had all the power before. The imperial prerogatives were formerly very extensive. At the close of the Saxon race, A.D. 1024, they exercised the right of conferring ecclesiastical benefices in Germany; of receiving the revenues of them during a vacancy; of succeeding to the effects of intestate ecclesiastics; of confirming or annulling the elections of the popes; of assembling councils, and of appointing them to decide concerning the affairs of the church; of conferring the title of king on their vassals; of

granting vacant fiefs; of receiving the revenues of the empire; of governing Italy as its proper sovereigns; of erecting free cities, and of establishing fairs in them; of assembling the diets of the empire, and of fixing the time of their duration; of coining money, and conferring the same privilege on the states of the empire; and of administering both high and low justice within the territories of the different states: but in the year 1437 they were reduced to the right of conferring all dignities and titles, except the privilege of being a state of the empire; of preces primariæ, or of appointing once during their reign a dignitary in each chapter or religious house; of granting dispensations with respect to the age of majority; of erecting cities, and conferring the privilege of coining money; of calling the meetings of the diet and presiding in them. To which some have added, 1. That all the princes and states of Germany were obliged to do them homage, and swear fidelity to them. 2. That they or their generals had a right to command the forces of all the princes of the empire, when united together, &c. The kings of France were anciently also called emperors, at the time when they reigned with their sons, whom they associated to the crown. Thus Hugh Capet, having associated his son Robert, took the title of emperor, Robert that of king; under which titles they are mentioned in the History of the Council of Rheims, by Gerbert, &c. King Robert is also called emperor of the French by Helgau of Fleury. Lewis the Gross, upon associating his son, did the same. The kings of England had likewise anciently an imperial title, as appears from a charter of king Edgar: Ego Edgarus Anglorum basileus, omniumque regum insularum oceani quæ Britanniam circumjacent, &c. imperator et dominus.—Napoleon Buonaparte, the late emperor of the French, when he assumed that title, in 1804, not only exercised the ancient imperial prerogative of making kings, but obliged the head of the German empire to resign his dignity as Emperor of Germany. See DIET, ELECTOR, and NAPOLEON.

EMPETRUM, berry-bearing heath. A genus of the triandria order, and diœcia class of plants. Male CAL. tripartite: COR. tripetalous; stamina long; the styles nine: BERRY nine-seeded. Two species, of which the E. nigrum, which bears the crow crake berries, is a native of Britain. It grows wild on boggy heaths and mountains. Children sometimes eat the berries; but, when taken in too great quantity, they are apt to occasion a headache. Grouse feed upon them. When boiled with alum, they afford a dark purple dye. Goats are not fond of it. Cows, sheep, and horses, refuse it.

EMPH'ASIS, *n. s.*, EMPHAT'IC, *adj.*, EMPHAT'ICAL, EMPHAT'ICALLY, *adv.* } Fr. *emphase;* Span. and Port. *emphasi;* Ital. *enfasi;* Lat. *emphasis;* Gr. ἐμφασις, from ἐν, expletive, and φασις, speech. Stress or force of pronunciation, and hence of style or argument. Browne uses emphatically as synonymous with apparently.

> Oh, that brave Cæsar!
> — Be choaked with such another *emphasis*.
> *Shakspeare.*

What is delivered of the incurvity of dolphins, must be taken *emphatically*, not really, but in appearance, when they leap above water, and suddenly shoot down again. *Browne.*

It is commonly granted, that *emphatical* colours are light itself, modified by refractions. *Boyle on Col.*

*Emphasis* not so much regards the time as a certain grandeur, whereby some letter, syllable, word, or sentence is rendered more remarkable than the rest, by a more vigorous pronunciation, and a longer stay upon it. *Holder.*

> Cellars and granaries in vain we fill,
> With all the bounteous summer's store;
> If the mind thirst and hunger still,
> The poor rich man's *emphatically* poor.
> *Cowley.*

How *emphatically* and divinely does every word proclaim the truth that I have been speaking of! *South.*

These questions have force and *emphasis*, if they be understood of the antediluvian earth. *Burnet's Theory.*

Where he endeavours to dissuade from carnivorous appetites, how *emphatical* is his reasoning! *Garth.*

In proper and *emphatick* terms thou didst paint the blazing comet's fiery tail. *Arbuthnot. John Bull.*

> Are they not his by a peculiar right,
> And by an *emphasis* of interest his,
> Whose eye they fill with tears of holy joy,
> Whose heart with praise, and whose exalted mind
> With worthy thoughts of that unwearied love,
> That planned, and built, and still upholds a world
> So clothed with beauty for rebellious man?
> *Cowper*

> Thus vowed she at the hallowed shrine,
> Though rashly, though without design·
> And uttered not, for modest dread,
> The last *emphatic* word, to wed;
> Which but to hear, much more to speak,
> With blushes paints a virgin's cheek. *Sheridan.*

EMPHYSE'MA, *n. s.*, EMPHYSEM'ATOUS, *adj.* } Gr. ἐμφυσημα, from ἐμφυσαω, to inflate. A humor of the body; bloated; stuffed.

*Emphysema* is a light puffy humor, easily yielding to the pressure of the finger, arising again in the instant you take it off. *Wiseman.*

The signs of a gangrene are these: the inflammation loses its redness, and becomes duskish and livid; the tenseness of the skin goes off, and feels to the touch flabby or *emphysematous*; and vesications, filled with ichor of different colours, spread all over it. *Sharp's Surgery.*

EMPHYSEMA is a windy tumor, generally occasioned by a fracture of the ribs, and formed by the air insinuating itself, by a small wound, between the skin and muscles, into the substance of the cellular or adipose membrane, spreading itself afterwards up to the neck, head, belly, and other parts, much after the manner in which butchers blow up their veal. See MEDICINE.

EMPIE'RCE, *v. a.* From pierce. To pierce into; to enter into by violent appulse.

> The weapon bright,
> Taking advantage of his open jaw,
> Ran through his mouth with so importune might,
> That deep *empierced* his darksome hollow maw.
> *Spenser.*

EMPI'GHT, *pret.* and *part.* From to pight, or pitch. See PITCH. Set; fixt; fastened.

> But he was wary, and ere it *empight*
> In the meant mark, advanced his shield atween.
> *Spenser.*

**Empire**, in political geography, a large extent of land, under the jurisdiction or government of an emperor. See Emperor. 1. In ancient history we read of four great empires, viz. 1 That of the Assyrians, Chaldeans, and Babylonians; 2. of the Medes and Persians; 3. of the Greeks; and 4. of the Romans. The first subsisted from the time of Nimrod, who founded it A.M. 1800, according to the computation of Usher, to Sardanapalus their last king, in 3257, and consequently lasted above 1450 years. The empire of the Medes commenced under Arbaces, A.M. 3257; was united to that of the Babylonians and Persians under Cyrus, A.M. 3468, and ended with the death of Darius Codomannus in 3674. The Grecian empire lasted only during the reign of Alexander the Great, beginning in A.M. 3674, and terminating with the death of this conqueror in 3681, when his conquests were divided among his captains. The Roman empire commenced with Julius Cæsar, when he was made perpetual dictator, in A.U.C. 708, A.M. 3956, and A.D. 48. The seat of the empire was removed to Byzantium by Constant'ne, A.D. 334, and the east and west were still considered as united under the title of the Roman empire though mostly governed by two different series of emperors, till the total overthrow of the latter under Augustulus, by the Goths, A.D. 476. The Western empire was not revived even in name, till the year 800, when Charles the Great, of France, was proclaimed emperor by the Romans. From this epoch the east and west formed two separate empires; that of the east, governed by Greek emperors, commenced A.D. 802: and, being gradually weakened, terminated under Constantine Palæologus in 1453. The western empire was afterwards known by the appellation of the empire, or German empire. Antiquaries distinguish between the medals of the upper and lower or base empire. The curious only value those of the upper empire, which commences with Cæsar or Augustus, and ends A.D. 260. The lower empire comprehends nearly 1200 years, reckoning down to the destruction of Constantinople in 1453. They usually distinguish two ages, or periods of the lower empire: the first beginning where the upper ends, viz. with Aurelian, and ending with Anastasius, including 200 years; the second beginning with Anastasius, and ending with the Palæologi, which includes 1000 years.

Empire, Eastern. See Constantinople.

Empire, Western. See Germany, and Rome.

EMPIR'IC, *n. s.* | Empir'icism, | Empir'ical, *adj.* | Empir'ically, *adv.* } Fr. *empirique;* Ital. Span. and Port. *empirico;* from the Gr. ἐμπειρικος, from ἐμπειρια, experience. See the article subjoined.

The name of Hippocrates was more effectual to persuade such men as Galen, than to move a silly *empirick*. *Hooke*.

The most sovereign prescription in Galen is but *empirick* to this preservative. *Shakspeare.*

And are manned
With ten *empirics*, in their chamber
Lying for the spirit of amber. *Ben Jonson.*

By fire
Of sooty coal, the *empirick* alchymist
Can turn, or holds it possible to turn,
Metals of drossiest ore to perfect gold. *Milton.*

That every plant might receive a name, according unto the diseases it cureth, was the wish of Paracelsus; a way more likely to multiply *empiricks* than herbalists. *Browne.*

We shall *empirically* and sensibly deduct the causes of blackness from originals, by which we generally observe things denigrated. *Browne's Vulgar Errours.*

Tho' illiterate writer, *empirick*-like applies
To each disease unsafe chance remedies;
The learned in school, when science first began,
Studies with care the anatomy of man. *Dryden.*

Such an aversion and contempt for all manner of innovators, as physicians are apt to have for *empiricks*, or lawyers for pettifoggers. *Swift.*

No; we waited, till the morbid strength of our boulimia for their physic had exhausted the well-stored dispensary of their *empiricism*. It is impossible to guess at the term to which our forbearance would have extended. *Burke.*

Empirics, in medical history, are a sect of physicians, who contended that all hypothetical reasoning respecting the operations of the animal economy was useless, and that observation and experience alone were the foundation of the art of medicine.

The origin of this sect is variously stated by different writers of antiquity. The empiric physicians themselves seem to have considered Acron of Agrigentum, a contemporary and rival of Empedocles, in the seventieth olympiad, as their founder; and Pliny has asserted the same opinion, in his sketch of the history of medicine. The best historians refer the establishment of this sect to about the 123rd olympiad; but they are not agreed as to the individual who first promulgated the doctrine of empiricism. Galen and others have ascribed the origin of the sect to Philinus of Cos, a disciple of Herophilus, to whom he was said to be indebted for the first hints of his system. Celsus, however, asserts, that Serapion was the first who maintained this doctrine. He was born, and practised medicine, at Alexandria, and appears to have been contemporary with Philinus. Observation, record, and the substitution of similar means, were the three fundamental resources of the art of medicine, according to the empirics; and these were denominated by Glaucias, and others, the tripod of medicine (τρίπης της ἰατρικῆς). Compared with this species of investigation, how futile are the speculations, misnamed philosophy in the schools, relative to elements, and essences, which had no existence, except in the imagination of the disputants. For it must be observed, that the ancient empirics did not disregard the dictates of reason and reflection; they only deprecated the application of them to circumstances out of the reach of the senses, and beyond the scope of experiment.

EMPIS, in zoology, a genus of insects belonging to the order diptera; of which the characters are these: the proboscis is of a horny substance, bivalve, reflexed under the head and breast, and longer than the thorax.

EMPLAS'TER, *v. a.* & *n. s.* } Fr. *emplâtre;*
EMPLAS'TIC, *adj.* } Span. *emplastro;* Lat. *emplastrum;* Gr. εμπλαστρον, from εμπλασσω, i. e. εν, and πλασσω, to form. To cover or hide with plaster: hence, to hide generally; emplastic is viscous; glutinous; like a plaster.

All *emplasters*, applied to the breast, ought to have a hole for the nipples. *Wiseman's Surgery.*

Resin, by its *emplastick* quality, mixed with oil of roses, perfects the concoction. *Id.*

*Emplastick* applications are not sufficient to defend a wound from the air. *Arbuthnot on Air.*

They must be cut out to the quick, and the sores *emplastered* with tar. *Mortimer's Husbandry.*

EMPLE'AD, *v. a.* From em and plead. To indict; to prefer a charge against; to accuse.

To terrify and torture them, their tyrannous masters did often *emplead*, arrest, cast them into prison, and thereby consume them to worse than nothing. *Hayward*

Antiquity thought thunder the immediate voice o. Jupiter, and *empleaded* them of impiety that referred it to natural casualties. *Glanville's Scepsis.*

Since none the living villains dare *emplead*,
Arraign them in the persons of the dead. *Dryden.*

EMPLEURUM, in botany, a genus of the monœcia tetrandria class and order. Male CAL. four-cleft: COR. none: stigma cylindric: CAPS. opening at the side: SEED one, arilled. There is one species, a shrub of the Cape.

EMPLOY', *v. a* & *n. s.* } Fr. *emploier;* Sp.
EMPLOY'ABLE, *adj.* } *emplear;* from Lat.
EMPLOY'ER, *n. s.* } *implere*, to fill (the
EMPLOY'MENT. } time). To occupy; to engage in business or work; used with *in*, *about*, *upon*, and less properly with *to;* applied both to time, persons, and things: employ, as a substantive, signifies business, public or private; and is synonymous with employment: employable, fit to be, or that may be employed.

Jonathan and Jahaziah were *employed about* this matter. *Ezra*, x. 15.

The money was *employed to* the making of gallies. 2 *Mac.*

Call not your stocks for me; I serve the king,
On whose *employment* I was sent to you.
*Shakspeare. King Lear.*

Those profitable agents, whose industry either fitteth them abroad for public *employment*, or *employeth* them, after due maturity, *in* the fit service of the commonwealth. *Bp. Hall.*

Their principal learning was applied to the course of the stars, and the rest was *employed in* displaying the brave exploits of their princes. *Temple.*

For thrice, at least, in compass of the year,
Thy vineyard must *employ* the sturdy steer
To turn the glebe. *Dryden's Virgil.*

To study nature will thy time *employ;*
Knowledge and innocence are perfect joy.
*Dryden.*

The labor of those who felled and framed the timber *employed about* the plough must be charged on labor. *Locke.*

The proper business of the understanding is not that, which men always *employ* it *to*. *Id.*

Labor in the beginning gave a right of property, wherever any one was pleased to *employ* it *upon* what was common. *Id.*

Lest animosities should obstruct the course of justice, if one of their own number had the distribution of it, they have always a foreigner for this employ. *Addison on Italy.*

This is a day in which the thoughts of our countrymen ought to be *employed on* serious subjects. *Addison's Freeholder.*

On the happy change, the boy
*Employed* his wonder and his joy. *Prior.*

The cleanly cheese-press she could never turn;
Her awkward fist did ne'er *employ* the churn. *Gay.*

The honours and the burdens of great posts and *employs* were joined together. *Atterbury.*

If any station, any *employment* upon earth be honourable, theirs was. *Id.*

Leaders on each side, instead of intending the public weal, have their hearts wholly set to get or to keep *employments*. *Swift.*

Present to grasp, and future still to find,
The whole *employ* of body and of mind. *Pope.*

That man drives a great trade, and is owner or *employer* of much shipping, and continues and increases in trade and shipping. *Child on Trade.*

The objections made against the doctrine of the chymists, seem *employable* against this hypothesis *Boyle.*

Jesus Christ is furnished with superiour powers to the angels, because he is *employed in* superiour works and appointed to be the sovereign Lord of all the visible and invisible worlds. *Watts.*

His high station in the church placed him in the way of great civil *employments;* his abilities were equal to the greatest of these; nor did he reckon any of them to be above his merit.
*Robertson. History of Scotland.*

Time, with all its celerity, moves slowly on to him whose whole *employment* is to watch its flight.
*Johnson.*

The prospect, such as might enchant despair,
He views it not, or sees no beauty there;
With aching heart, and discontented looks,
Returns at noon to billiards or to books,
But feels, while grasping at his faded joys,
A secret thirst of his renounced *employs*. *Cowper.*

EMPOI'SON, *v. a.* } Fr. *empoisonner;* from
EMPOI'SONER, *n. s.* } em and POISON, which
EMPOI'SONMENT. } see. To kill or destroy by poison.

Mushrooms cause the incubus, or mare in the stomach, therefore the surfeit of them may suffocate and *empoison*. *Bacon.*

He is vehemently suspected to have been the *poisoner* of his wife, thereby to make vacant his bed. *Bacon's Henry VII.*

Leaving no means unattempted of destroying his son, that wicked servant of his undertook to *empoison* him. *Sidney.*

Even in the peaceful rural vale,
Truth, weeping, tells the mournful tale,
How pampered Luxury, Flattery by her side,
The parasite *empoisoning* her ear,
With all the servile wretches in the rear,
Looks o'er proud property, extended wide.
*Burns.*

EMPORIÆ, a double city of the Hither Spain near the Pyrenees: separated by a wall; one part occupied by the Greeks of Phocæa, whence originally are the Massilienses; the other by native Spaniards, to whom was added by Augustus a Roman colony. It is now called AMPURIAS; which see.

EMPOR'IUM, *n. s.* Lat. *emporium;* Gr. εμποριον; εμπορος, is a merchant, from εν and πειρω, to pass over; to travel. A place of concourse for merchants; a mart for trade.

And while this tamed emporium we prepare,
The British ocean shall such triumphs boast,
That those who now disdain our trade to share,
Shall rob like pirates on our wealthy coast. *Dryden.*

I take the prosperous estate of this great *emporium* to be owing to those instances of charity. *Atterbury.*

EMPORIUM, in ancient geography, the name of two cities in Italy, near Placentia; the one well fortified, and guarded by a strong garrison, at which Hannibal met a repulse: the other Hannibal took and plundered. They are now thought to be Ponte Nura, in Placentia.

EMPOV'ERISH, *v. a.* } Fr. *empauvre*; Ital.
EMPOV'ERISHER, *n. s.* } *empoverire*; Span.
EMPOV'ERISHMENT. } and Port. *empobrecer*; from Fr. *pauvre*, which from Lat. *pauper*, poor. To make poor; depauperate: an empoverisher is one who makes poor, wastes, or deteriorates.

Being paid as it is, now some, and then some, it is no great burden unto her, nor any great *empoverishment* to her coffers. *Spenser. State of Ireland.*

Your's sounds aloud, and tells us you excel
No less in courage than in singing well;
While, unconcerned, you let your country know,
They have *empoverished* themselves, not you. *Waller.*

Since they might talk better as they lay together, they *empoverished* their clothes to enrich their bed, which, for that night, might well scorn the shrine of Venus. *Sidney.*

For sense of honour, if it *empoverisheth* a man, it is, in his esteem, neither honour nor sense. *South.*

Fresh roses bring,
To strow my bed, 'till the *empoverished* Spring
Confess her want. *Prior.*

All appeals for justice, or appellations for favour or preferment to another country, are so many grievous *impoverishments*. *Swift's View of Ireland.*

They destroy the weeds and fit the land for aftercrops, being an improver, and not an *empoverisher* of land. *Mortimer.*

EMPO'WER, *v. a.* From em and power.

You are *empowered*, when you please, to give the final decision of wit. *Dryden's Juvenal, Dedication.*

The government shall be *empowered* to grant commissions to all Protestants whatsoever. *Swift.*

Does not the same power that enables them to heal, *empower* them to destroy? *Baker on Learning.*

The duchess of Munster obtained a patent, *empowering* him [Mr. Wood] to coin 180,000 pounds of halfpence and farthings for the kingdom of Ireland. *Johnson. Life of Swift.*

[James I.] obtained an act by which he was *empowered* to summon such as had obtained crown lands during the three last reigns, to produce the rights by which they held them. *Robertson. History of Scotland.*

EM'PRISE, *n. s.* Fr. *emprise*; an abbreviation of enterprise. Hazardous or chivalrous undertaking.

Therefore whylome to knights of great *emprise*
The charge of justice given on trust,
That they might execute her judgments wise,
And with their might beat down licentious lust,
Which proudly did impugn her sentence just.
*Spenser. Faerie Queene.*

Noble minds, of yore, allied were
In brave pursuit of chivalrous *emprise*. *Id.*

A double conquest must you make,
If you atchieve renown by this *emprise*. *Fairfax.*

Fierce faces threatening wars;
Giants of mighty bone, and bold *emprise*. *Milton.*

Thus, 'till the sun had travelled half the skies,
Ambushed we lie, and wait the bold *emprise*. *Pope.*

EMP'TION, *n. s.* Old Fr. *emption*; Lat. *emptio*; from the verb *emo*, *emptus*, to buy. The act of purchasing; or a purchase made.

There is a dispute among the lawyers, whether Glaucus his exchanging his golden armour with the brazen one of Tydides, was *emption* or commutation. *Arbuthnot on Coins.*

EMP'TY, *v. a.* & *n.* & *adj.* } Sax. æmꝑꞇıᵹ,
EMP'TIER, *n. s.* } æmꝑꞇıan, to make
EMP'TINESS. } void. To exhaust; evacuate; deprive of contents; to become exhausted or void: an emptier is one who makes any thing or place void; emptiness the state of vacuity.

The pit was *empty*, there was no water in it. *Genesis.*

Seven *empty* ears blasted with the east wind. *Id.*

Israel is an *empty* vine. *Hosea.*

The *emptiers* have *emptied* them out, and marred their vine-branches. *Nahum*, ii. 2.

They beat him, and sent him away *empty*. *Matthew.*

Heres hore aren shad overtimeliche upon my hed: and the slacke skinne tremblethe of mine *empted* bodie. *Colvile.*

Himself he frees by secret means unseen,
His shackles *empty* left, himself escaped clean. *Spenser.*

I did never know so full a voice issue from so *empty* a heart; but the saying is true, the *empty* vessel makes the greatest sound. *Shakspeare.*

Art thou thus boldened, man, by thy distress,
That in civility thou seem'st so *empty*? *Id.*

Boundless intemperance,
In nature is a tyranny: it hath been
The untimely *emptying* of the happy throne,
And fall of many kings. *Shakspeare. Macbeth.*

His coffers sound
With hollow poverty and *emptiness*. *Shakspeare.*

How comes it that so many worthy and wise men depend upon so many unworthy and *empty* headed fools! *Raleigh.*

Foure things are grievously *empty*: a head without brains, a wit without judgment, a heart without honesty, and a purse without money. *Bp. Earle.*

He alledges that satyrs carried platters full of fruit in their hands; but if they had been *empty* handed, had they been ever the larger satyrs? *Dryden.*

Yet all the little that I got, I spent;
And still returned as *empty* as I went. *Id.*

Nor could another in your room have been,
Except an *emptiness* had come between. *Id.*

Yet this insignificancy in their words, when they come to reason concerning either their tenets or interest, manifestly fills their discourse with abundance of *empty* unintelligible noise and jargon, especially in moral matters. *Locke.*

Where cities stood,
Well fenced, and numerous, desolation reigns,
And *emptiness*; dismayed, unfed unhoused,
The widow and the orphan stroll. *Philips.*

If you have two vessels to fill, and you empty one to fill the other, you gain nothing by that; there still remains one vessel *empty*. *Burnet.*

His answer is a handsome way of exposing an *empty*, trifling, pretending pedant; the wit lively, the satyr courtly and severe. *Felton.*

The ordinary air in which we live and respire, is of so thin a composition, that 16,149 parts of its di-

mensions are mere *emptiness* and nothing; and the remaining one only, material and real substance. *Bentley*.

Mr. Boyle has showed, that air may be rarefied above 10,000 times in vessels of glass; and the heavens are much *emptier* of air than any vacuum we can make below. *Newton*.

I have always observed that your *empty* vessels sound loudest. *Swift*.

Form the judgment about the worth or *emptiness* of things here, according as they are or are not of use, in relation to what is to come after. *Atterbury*.

Pleased in the silent shade with *empty* praise. *Pope*.

Eternal smiles his *emptiness* betray,
As shallow streams run dimpling all the way. *Id*.

The Euxine Sea is conveniently situated for trade, by the communication it has both with Asia and Europe, and the great navigable rivers that *empty* themselves into it. *Arbuthnot*.

Sheep are often blind by fulness of blood: cut their tails, and *empty* them of their blood. *Mortimer*.

Since pulpits fail, and sounding-boards reflect
Most part an *empty* ineffectual sound,
What chance that I, to fame so little known,
Nor conversant with men or manners much,
Should speak to purpose, or with better hope,
Crack the satiric thong? *Cowper*.

Hope sets the stamp of vanity on all
That men have deemed substantial since the fall,
Yet has the wondrous virtue to educe
From *emptiness* itself a real use. *Id*.

Blaze round each frosted rill, or stagnant wave,
And charm the Naiad from her silent cave;
Where, shrined in ice, like Niobe she mourns,
And clasps with hoary arms her *empty* urns. *Darwin*.

Their sceptre broken, and their sword in rust,
Have yielded to the stranger: *empty* halls,
Thin streets, and foreign aspects, such as must
Too oft remind her who and what enthrals,
Have flung a desolate cloud o'er Venice' lovely walls. *Byron*.

EMPU'RPLE, *v. a.* From em and purple. To make of a purple color; to discolor with purple.

Now in loose garlands, thick thrown off, the bright
Pavement, that like a sea of jasper shone,
*Empurpled* with celestial roses smiled. *Milton*.
The deep,
*Empurpled* ran, with gushing gore distained. *Philips*.

EMPU'ZZLE, *v. a.* From em and puzzle. To perplex; to put to a stand.

It hath *empuzzled* the enquiries of others to apprehend, and enforced them unto strange conceptions to make out. *Browne*.

EMPYE'MA, *n. s.* Fr. *empyemé*; Gr. εμπυημα, from εν, within, and πυων, pus. A collection of purulent matter in any part of the body, but more particularly in the cavity of the chest. See MEDICINE, Index.

An *empyema*, or a collection of purulent matter in the breast, if not suddenly cured, doth undoubtedly impel the patient into a phthisical consumption. *Harris*.

There is likewise a consumption from an *empyema*, after an inflammation of the lungs. *Arbuthnot*.

EMPY'REAN, *n. s. & adj.*
EMPY'REAL, *adj.*
EMPY'REUM, *n. s.*
} Fr. *empyrée*; Ital., Span. and Port. *cielo empireo*; Lat. *empyrium*, from Gr. εμπυρος, i. e. εν and πυρ, fire. The highest heaven, supposed to consist of pure fire.

Under his burning wheel
The stedfast *empyrean* shook throughout,
All but the throne itself of God.
*Milton. Paradise Lost*.

Now went forth the morn,
Such as in highest heaven, arrayed in gold
*Empyreal*. *Id*.

And fix our engines, and our ensigns,
Upon the fixt stars' vast dimensions,
—— And prove if they are other suns,
As some have held opinions,
Or windows in the *empyreum*,
From whence those bright effluvia come
Like flames of fire. *Butler*.

But *empyreal* forms, howe'er in sight
Gashed and dismembered easily unite. *Tickell*.

Go, soar with Plato to the *empyreal* sphere,
To the first good, first perfect, and first fair. *Pope*.

How nitrous gas from iron ingots driven
Drinks with red lips the purest breath of heaven;
How, while conferva from its tender hair
Gives in bright bubbles *empyrean* air,
The crystal floods phlogistic ores calcine,
And the pure ether marries with the mine. *Darwin*.

EMPYRE'UM, *n. s.*
EMPYREUMAT'IC, *adv.*
EMPYREUMAT'ICAL,
} Fr. *empyreme*; Greek, εμπυρευμα, from the verb εμπυραω, to burn. The burning or boiling of oils, or other matters that give an offensive smell. Empyreumatic is having this burnt, oily smell or taste.

*Empyreumatical* oils, distilled by strong fires in retorts, may be brought to emulate essential oils drawn in limbicks. *Boyle*.

It is so far from admitting an *empyreum*, that it burns clear away without leaving any cinders, or a dust about it. *Harvey*.

The hopes of an elixir insensibly evaporate, and vanish into air, or leave in the recipient a foul *empyreum*. *Decay of Piety*.

EMPY'ROSIS, *n. s.* Gr. εμπυροω. Conflagration; general fire.

The former opinion that held these cataclysms and *empyroses* universal, was such as held that it put a total consummation unto things in this lower world, especially that of conflagration. *Hale*.

EMRUN, or EMBRUN, an ancient town of France, the chief place of a district, in the department of the Alps: it is situated on the Durance, in the midst of fertile vallies, and is chiefly remarkable for its cathedral. Inhabitants about 3000.

EMS, a considerable river of Westphalia, which rises in the principality of Paderborn, and flows through Munster and East Friesland. It finally discharges itself by two arms into the bay of Dollart in the North Sea, a little below Embden. It has a mouth of noble breadth, and the tide, rising for a number of miles, renders it an important medium of transport.

EM'ULE, *v. a.*
EM'ULATE, *v. a.* & *adj.*
EMULA'TION, *n. s.*
EM'ULATIVE, *adj.*
EM'ULATOR, *n. s.*
EM'ULOUS, *adj.*
EM'ULOUSLY, *adv.*

French, *emuler*; Span. *emular*; It. *emulare*; Latin, *æmulor*, from Gr. αμιλλα, a contest. To rival; strive with for excellence; hence to imitate or equal generally. Shakspeare uses the adjective emulate for ambitious. Emulative is disposed, or tending to, rivalry. Emulous, rivalling; desirous to outvie; hence contentious, factious.

There was neither envy nor *emulation* amongst them. *1 Mac.*

He sitting me beside, in that same shade,
Provoked me to play some pleasant fit;
Yet *emuling* my pipe, he took in hand
My pipe, before that *emuled* of many,
And plaid thereon; for well that skill he could. *Spenser.*

I see how thy eye would *emulate* the diamond. *Shakspeare.*

Our last king,
Whose image even but now appeared to us,
Was, as you know, by Fortibras of Norway,
Thereto pricked on by a most *emulate* pride,
Dared to the combat. *Id.*

Mine *emulation*
Hath not that honour in't it had; for where
I thought to crush him in an equal force,
True sword to sword, I'll pitch at him some way,
Or wrath or craft may get him. *Id.*

What madness rules in brainsick men,
When for so slight and frivolous a cause,
Such factious *emulations* shall arise! *Id.*

Whose glorious deeds, but in the fields of late,
Made *emulous* missions 'mongst the gods themselves,
And drave great Mars to faction. *Id.*

In superiours it quencheth jealousy, and layeth their competitors and *emulators* asleep. *Bacon.*

I would have
Him *emulate* you: 'tis no shame to follow
The better precedent. *Ben Jonson's Catiline.*

What the Gaul or Moor could not effect,
Nor *emulous* Carthage, with their length of spite,
Shall be the work of one. *Id.*

Nothing will more try a man's grace, than questions of *emulation*. *Bp. Hall. Contemplations.*

Whether some secret and *emulatory* brawls passed between Zipporah and Miriam, or whether now that Jethro and his family were joined with Israel, &c. the exceptions were frivolous. *Id.*

She is in perpetual diffidence, or actual enmity with her, but always *emulous* and suspectful of her. *Howel's Vocal Forest.*

As long as the world lasts, and honour and virtue and industry have reputation in the world, there will be ambition and *emulation* and appetite in the best and most accomplished men who live in it. *Clarendon.*

By strength
They measure all, of other excellence
Not *emulous*, nor care who them excels. *Milton.*

So tempt they him, and *emulously* vie
To bribe a voice, that empires would not buy. *Granville.*

Those fair ideas to my aid I'll call,
And *emulate* my great original. *Dryden.*

A noble *emulation* heats your breast,
And your own fame now robs you of your rest:
Good actions still must be maintained with good,
As bodies nourished with resembling food. *Id.*

The apostle exhorts the Corinthians to an holy and general *emulation* of the charity of the Macedonians, in contributing freely to the relief of the poor saints at Jerusalem. *South.*

Aristotle allows that some *emulation* may be good, and may be found in some good men; yet envy he utterly condemns, as wicked in itself, and only to be found in wicked minds. *Spratt.*

I promise myself you will look with an eye of favour upon a meeting which owes its original to a mutual *emulation* among its members, who shall show the most profound respect for your paper. *Spectator.*

Good Howard, *emulous* of the Grecian art. *Prior.*

It is likewise attended with a delirium, fury, and an involuntary laughter, the convulsion *emulating* this motion. *Arbuthnot.*

What though no weeping loves thy ashes grace,
Nor polished marble *emulate* thy face. *Pope.*

Each of the rivals courted him with *emulation*; he knew it to be his interest to keep the balance even, and to restrain both, by not joining entirely with either of them. *Robertson. History of Scotland.*

Rhyme, except some religious pieces that are in print, I had given up; but meeting with Ferguson's Scottish Poems, I strung anew my wildly-sounding lyre with *emulating* vigour. *Burns.*

Peace (if insensibility may claim
A right to the meek honours of her name)
To men of pedigree; their noble race,
*Emulous* always of the nearest place
To any throne, except the throne of grace. *Cowper.*

True *emulation*, especially in young and ingenuous minds, is a noble principle; I have known the happiest effects produced by it; I never knew it to be productive of any vice. In all public schools, it is, or ought to be, carefully cherished. *Beattie.*

SNEER. Why, 'tis certain, that unnecessarily to mortify the vanity of any writer is a cruelty which mere dulness never can deserve; but where a base and personal malignity usurps the place of literary *emulation*, the aggressor deserves neither quarter nor pity. *Sheridan.*

EMULGE', *v. a.*
EMUL'GENT, *adj.*
EMUL'SION, *n. s.*

Fr. *emulgente*; Latin, *emulgeo*, *emulgens*; *e* and *emulgeo*; Gr. αμελγω. To milk out. Emulgent is milking or draining out. Emulsion, a form of medicine, by bruising oily seeds and kernels, and drawing out their substances with some liquor, that thereby becomes milky.

It doth furnish the left *emulgent* with one vein. *Browne.*

Through the *emulgent* branches the blood is brought to the kidneys, and is there freed of its serum. *Cheyne.*

The aliment is dissolved by an operation resembling that of making an *emulsion*; in which operation the oily parts of nuts and seeds, being gently ground in a marble mortar, are gradually mixed with some watery liquor, or dissolved into a sweet, thick, turbid, milky liquor, resembling the chyle in an animal body. *Arbuthnot.*

EMUNCTORIES, *n. s.* Fr. *emunctoire*; Ital. *emuntorio*; Lat. *emunctoria*; from *e* and *mungo*; Gr. μυζω, μυγω. To wipe the nose. Those parts of the body where any thing excrementitious is separated and collected for ejectment.

There are receptacles in the body of man, and *emunctories* to drain them of superfluous choler. *More*

Superfluous matter deflows from the body under their proper *emunctories*. *Browne's Vulgar Errours.*

Discoursing of the lungs, I shew that they are the grand *emunctory* of the body; that the main end of respiration is continually to discharge and expel an excrementitious fluid out of the mass of blood. *Woodward's Natural History.*

The regimen in quinsies, which proceed from an obstruction of the glands, must be to use such warm liquors as relax those glands, such as, by stimulating, open the *emunctories* to secrete the humour. *Arbuthnot.*

EMUNCTORIES, in anatomy, are chiefly the kidneys, bladder, and most of the glands.

EN, an inseparable particle, says Dr. Johnson, borrowed by us from the French, and by the French from the Latin *in*. Many words are uncertainly written with *en* or *in*. In many words *en* is changed into *em* for more easy pronunciation. Ben Jonson had previously noticed that 'the letters *i* and *e* have such nearness in our tongue as oftentimes to interchange places.' *En* abounds in our older writers. Mr. Todd has very well suggested, that the uncertainty with respect to *en* or *in* might be removed by due attention to the etymology of words. 'Thus, as entire is admitted to be derived from the French *entier*, the form of intire should not be observed; thus enquire, as being from the French *enquirer*, seems preferable to inquire, from the Latin *inquiro*; and enclose, from the French *enclos*, to the Latin *inclusus*; while, on the other hand, include is directly from the Latin *includo*.'

ENA'BLE, *v. a.* From en and ABLE, which see. To empower; make able, or competent.

If thou wouldst vouchsafe to overspread
Me with the shadow of thy gentle wing,
I should *enabled* be thy acts to sing. *Spenser.*

This purifying of wit, this enriching of memory *enabling* of judgment, and enlarging of conceit, which commonly we call learning; under what name soever it be directed, the final end is, to lead and draw us to as high perfection as our degenerate souls (made worse by their clay lodgings), can be capable of. *Sir P. Sidney.*

The improvement of the understanding is for two ends: first, our own increase of knowledge; secondly, to *enable* us to deliver and make out that knowledge to others. *Locke.*

His great friendship with God might *enable* him, and his compassion might incline him. *Atterbury.*

He points out to him the way of life, strengthens his weakness, restores his lapses, and *enables* him to walk and persevere in it. *Rogers.*

The authority of an umpire, which had been unwarily bestowed upon him, and from which the Scots dreaded no dangerous consequences, *enabled* him to execute his schemes with greater facility. *Robertson. History of Scotland.*

ENACT', *v. a.* } From en and ACT, which
ENACTOR, *n. s.* } see. To act; perform; accomplish; establish by legal acts; represent by action. Shakspeare uses enactors (fol. edit.) in the last sense.

There are dreadful punishments *enacted* against thieves *Sir T. More.*

In true balancing of justice, it is flat wrong to punish the thought or purpose of any before it be *enacted*. *Spenser.*

Valiant Talbot, above human thought,
*Enacted* wonders with his sword and lance. *Shakspeare*

It is *enacted* in the laws of Venice,
If it be proved against an alien,
He seeks the life of any citizen,
The party 'gainst the which he doth contrive,
Shall seize on half his goods *Id.*

I did *enact* Hector. *Id.*

The violence of either grief or joy,
Their own *enactors* with themselves destroy. *Id.*

The senate were authors of all counsels in the state; and what was by them consulted and agreed, was proposed to the people, by whom it was *enacted* or commanded. *Temple.*

He acts also contrary to his trust, when he either employs the force, treasure, and offices of the society, to corrupt the representatives, and gain them to his purposes: or employs them to bring in such, who have promised beforehand what to vote, and what to *enact*. *Locke.*

The great author of our nature, and *enactor* of this law of good and evil, is highly dishonoured. *Atterbury.*

Next, while on pausing step the masked Mimes
*Enact* the triumphs of forgotten times,
Conceal from vulgar throngs the mystic truth,
Or charm with Wisdom's lore the initiate youth. *Darwin.*

'Hath God indeed given appetites to man,
And stored the earth so plenteously with means,
To gratify the hunger of his wish;
And doth he reprobate, and will he damn,
The use of his own bounty? making first
So frail a kind, and then *enacting* laws
So strict, that less than perfect must despair?' *Cowper.*

ENA'LLAGE, *n. s.* Gr. ἐναλλαγη. A figure in grammar, whereby some change is made of the common modes of speech, as when one mood or tense of a verb is put for another.

The grammarians too have a kind of *enallage*, whereby one part of speech, or one accident of a word, is put for another. Such is the change of a pronoun, as when a possessive is put for a relative, e. gr. suus for ejus; or of a verb, as when one mood or tense is put for another. *Dr. A Rees.*

ENA'MBUSH, *v. a.* From ambush. To hide in ambush; to hide with hostile intention.

They went within a vale, close to a flood, whose stream
Used to give all their cattle drink, they there *enambushed* them. *Chapman's Iliad.*

ENAM'EL, *v. a., v. n.* & *n. s.* } From en and
ENAM'ELLER, *n. s.* } AMEL, which
ENAM'ELLING. } see. French *emailler*; Span. and Port. *esmultar*. To inlay; fix colors by fire; variegate with colors. As a neuter verb, to practice inlaying or enamelling. As a substantive, it means the substance or work on which this art is performed. See below

Let dainty wits cry on the sisters nine,
That, bravely masked, their fancies may be told:
Or, Pindar's apes, flaunt they in phrases fine,
*Enamelling* with pyed flowers their thoughts of gold. *Sir P. Sidney.*

Thy graces and good works my creatures be;
I planted knowledge and life's tree in thee;
Which, oh! shall strangers taste? must I, alas!
Frame and *enamel* plate, and drink in glass? *Donne.*

Down from her eyes welled the pearles round,
Upon the bright *enamel* of her face;
Such honey drops on springing flowers are found,
When Phœbus holds the crimson morn in chace. *Fairfax.*

Higher than that wall, a circling row
Of goodliest trees, loaden with the fairest fruit,
Blossoms, and fruits at once of golden hue,
Appeared with gay *enamelled* colours mixed.
*Milton.*

Though it were foolish to colour or *enamel* upon the glasses of telescopes, yet to gild the tubes of them may render them more acceptable to the users, without lessening the clearness of the object.
*Boyle.*

There are various sorts of coloured glasses, pastes, enamels, and factitious gems. *Woodward on Fossils.*

See Pan with flocks, with fruits Pomona crowned;
Here blushing Flora paints the *enamelled* ground.
*Pope.*

His ears and legs,
Fleaked here and there, in gay *enamelled* pride,
Rival the speckled pard. *Somerville.*

These calces, therefore, when mixed with the enamel flux, are melted in crucibles, once or oftener, and the deep coloured opaque glass, thence resulting, is ground into impalpable power, and used for *enamel*.
*Darwin.*

Ah, why should the glittering stream
Reflect thus delusive the scene?
Ah, why does a rosy-tinged beam
Thus vainly *enamel* the green? *Sheridan.*

The substance of the *enamel* is a fine white opaque glass, the material of which will be presently mentioned. This is bought in lump by the *enamellers*, and is first broken down with a hammer, then ground to a sufficiently fine powder, with some water in an agate mortar. *Dr. M. Good.*

On most *enamellings*, and especially on this, it is necessary also to counter-*enamel* the under concave surface of the copper-plate, to prevent its being drawn out of its true shape. *Id.*

ENAMELLING, in painting and the fine arts, is the art of variegating with colors laid upon or into another body. Also a mode of painting, with vitrified colors, on gold, silver, copper, &c., and of melting it at the fire, or of making divers curious works in it at a lamp. This art is of so great antiquity as to render it difficult or impossible to trace it to its origin. It was evidently practised by the Egyptians, from the remains that have been observed on the ornamented envelopes of mummies. From Egypt it passed into Greece, and afterwards into Rome and its provinces, whence it was probably introduced into this country, as various Roman antiquities have been dug up in different parts of Britain, particularly in the Barrows, in which enamels have formed portions of the ornaments. The following are instances in proof of the antiquity of the art in this country: a jewel found at Athelney in Somersetshire, and preserved at Oxford, bears witness to it, and, by an inscription upon it, there is no doubt it was made by order of Alfred. The gold cup given by king John to the corporation of Lynn in Norfolk, proves that the art was known among the Normans, as the sides of the cup are embellished with various figures, whose garments are partly composed of colored enamels. The tomb of Edward the Confessor in Westminster Abbey, built in the reign of Henry III., is ornamented with enamels; and a crosier of William of Wykeham, in the time of Edward III., exhibits curious specimens of the application of the art of enamelling.

Enamels are vitrifiable substances, and are usually arranged into three classes, namely, the transparent, the semitransparent, and the opaque. The basis of all kinds of enamel is a perfectly transparent and fusible glass, which is rendered either semitransparent or opaque by the admixture of metallic oxides. M. Klaproth, some years ago, read to the Royal Academy of Sciences of Berlin a very elaborate paper, the result of much research, 'On the pastes, colored glasses, and enamels of the ancients.' From this we learn that the art of coloring glass seems to be of nearly the same antiquity as the invention of making it, which is proved, not only from written documents, but likewise by the variously colored glass corals with which several of the Egyptian mummies are decorated. This art supposes the possession of some chemical knowledge of the metallic oxides, because these are the only substances capable, as far as we now know, of producing such an effect. Still a difficulty occurs: what were the means and processes employed by the ancients for this purpose? as they had no acquaintance with the mineral acids, which at present are usually employed in the preparation of metallic oxides.

It is, however, certain that the art of giving various colors to glass must have obtained a considerable degree of perfection, as Pliny mentions the artificial imitation of the carbuncle, which was, at that time, a gem in the highest estimation. During the reign of Augustus, the Roman architects began to make use of colored glass in their Mosaic decorations: thus it is known that an application of glass pastes was resorted to in a villa built by the emperor Tiberius on the island of Capri. Several specimens of this coming into the possession of Klaproth, were subjected, by that able chemist, to a chemical analysis; and he has detailed a very particular account of the several processes which he performed to ascertain the component parts of the different colored glasses found in the ruins of the abovementioned villa. His first attempt was upon the antique red glass, of which the color is described as of a lively copper red. The mass was opaque and very bright at the place of fracture; and, of two hundred grains finely triturated, he found the constituent parts to be,

| | Grains. |
|---|---|
| Silex | 142 |
| Oxide of lead | 28 |
| Oxide of copper | 15 |
| Oxide of iron | 2 |
| Alumine | 5 |
| Lime | 3 |
| | 195 |
| Loss | 5 |
| | 200 |

On comparing the external characters of this red glass paste with the cupreous scoriæ of a lively brown red, such as is sometimes obtained on melting copper ores; M. Klaproth imagines that the ancients did not compound the abovementioned paste directly from its constituent parts, but instead of them employed, perhaps, copper scoriæ. And he adds, on this

supposition, they had nothing more to do than to select the best colored pieces to fuse and cast them into plates.

*In green glass he found the constituent parts the same as in the red, but in different proportions. Both receive their color from copper;* and the reason why this metal produces in the one a red, and in the other a green color, depends on the different degrees of its oxigenation; it being an ascertained fact, that copper, in the state of a suboxide, that is, only half saturated with oxygen, produces a reddish enamel, but, when fully saturated with oxygen, the enamel yielded is green.

M. Klaproth next analysed the blue glass paste, in which he found, next to the silex, that the oxide of iron is the most predominating article. He expected to find that the color had been given by cobalt, but could not discover the smallest trace of it, and therefore he infers that its blue color entirely depends on the iron. This excited in him no surprise, knowing that iron, under certain circumstances, is capable of producing a blue enamel, as is clearly exhibited by the beautiful blue colored scoriæ of iron, which are frequently met with in the highly heated furnaces on smelting iron stones. Our object in referring to these experiments is the fact that the colored glass pastes of the ancients agree, in many respects, with modern enamels.

White enamels are composed by melting the oxide of tin with glass, and adding a small quantity of manganese to increase the brilliancy of the color. The addition of oxide of lead or antimony produces a yellow enamel; but a more beautiful yellow may be obtained from the oxide of silver. Reds are formed by an intermixture of the oxides of gold and iron, that composed of the former being the most beautiful and permanent. Greens, violets, and blues are formed from the oxides of copper, cobalt, and iron; and these, when intermixed in different proportions, afford a great variety of intermediate colors. Sometimes the oxides are mixed before they are united to the vitreous bases. Such are, according to this author, the principal ingredients employed in the production of various enamels; but the proportions in which they are used, as well as the degree and continuance of the heat necessary to their perfection, constitute the secrets of the art. Besides these there are probably other substances occasionally used in the composition of enamels, and it has been asserted that the peculiar quality of the best kinds of Venetian enamel is owing to the admixture of a particular substance found on Mount Vesuvius, and ascertained to be thrown up by that volcano.

The principal quality of good enamel, and that which renders it fit for being applied on baked earthenware or on metals, is the facility with which it acquires lustre by a moderate heat, or cherry-red heat, more or less, according to the nature of the enamel, without entering into complete fusion. Enamels applied to earthenware and metals possess this quality. They do not enter into complete fusion; they assume only the state of paste, but of a paste exceedingly firm; and yet when baked one might say that they had been completely fused. There are two methods of painting on enamel: on raw or on baked enamel. Both these methods are employed, or may be employed, for the same object. Solid colors capable of sustaining the fire necessary for baking enamel ground, may be applied in the form of *fused enamel on that which is raw, and the artist may afterwards finish with the tender colors.* The colors applied on the raw material do not require any flux; there is one, even, to which silex must be added; that is, the calx of copper, which gives a very beautiful green: but, when you wish to employ it on the raw material, you must mix with it about two parts of its weight of silex, and bring the mixture into combination by means of heat. You afterwards pulverise the mass you have thus obtained, in order to employ it. To obtain good white enamel, it is of great importance that the lead and tin should be very pure. If these metals contain copper or antimony, as is often the case, the enamel will not be beautiful. Iron is the least hurtful.

*Of colored Enamels.*—All the colors may be produced by the metallic oxides. These colors are more or less fused in the fire, according as they adhere with more or less strength to their oxygen. All metals which readily lose their oxygen, cannot endure a great degree of heat, and are unfit for being employed on the raw materials.

Purple.—This color is the oxide of gold, which may be prepared different ways, as by precipitating, by means of a muriatic solution of tin, a nitro-muriatic solution of gold much diluted in water. The least quantity possible of the solution of tin will be sufficient to form this precipitate. The solution of tin must be added gradually, until you observe the purple color begin to appear: you then stop, and, having suffered the color to be deposited, you put it into an earthen vessel to dry slowly. The different solutions of gold, in whatever manner precipitated, provided the gold is precipitated in the state of an oxide, give always a purple color, which will be more beautiful in proportion to the purity of the oxide, but neither the copper or silver with which gold is generally found alloyed injure this color in a sensible manner: it is changed, however, by iron. The gold precipitate, which gives the most beautiful purple, is certainly fulminating gold, which loses that property when mixed with fluxes. Purple is an abundant color, it is capable of bearing a great deal of flux; and in a small quantity communicates its color to a great deal of matter. It appears that saline fluxes are better suited to it than those in which there are metallic calces. Those, therefore, which have been made with silex, chalk, and borax, or white glass, borax, and a little white oxide of antimony, with a little nitre, as I have already mentioned, ought to be employed with it. Purple will bear from four to twenty parts of flux, and even more, according to the shade required. Painters in enamel employ generally for purple a flux which they call brilliant white. This flux appears to be a semi-opaque enamel, which has been drawn into tubes, and afterwards blown into a ball at an enameller's lamp. These bulbs are afterwards broken in such a manner, that the flux is found

in small scales, which appear like the fragments of small hollow spheres. Enamel painters mix this flux with a little nitre and borax. This matter, which produces a very good effect, was employed without attempting to decompose it. It may be a very fusible common white enamel which has been blown into that form. It is to be remarked, that purple will not bear a strong heat; and the color is always more beautiful if the precipitate is ground with the flux before it has become dry.

Red.—We have no metallic oxide capable of giving directly a fused red; that is to say, we have no metallic calces which, entering into fusion and combining, under the form of transparent glass, with fluxes or glass, give directly a red color. To obtain this color, it must be compounded different ways, as follows:—Take two parts, or two parts and a half (you may, however, take only one part) of sulphate of iron and of sulphate of alumine, fuse them together in their water of crystallisation, and take care to mix them well together. Continue to heat them to complete dryness, then increase the fire so as to bring the mixture to a red heat. The last operation must be performed in a reverberating furnace. Keep the mixture red until it has every where assumed a beautiful red color, which you may ascertain by taking out a little of it from time to time, and suffering it to cool in the air. You may then see whether the matter is sufficiently red: to judge of this it must be left to cool, because while hot it appears black. The red oxides of iron give a red color; but this color is exceedingly fugitive; for, as soon as the oxide of iron enters into fusion, the portion of oxygen, which gives it its red color, leaves it, and it becomes black, yellow, or greenish. To preserve, therefore, the red color of this oxide in the fire, it must be prevented from vitrifying and abandoning its oxygen. I have tried (says M. Clouet) a variety of different substances to give it this fixity, but none of them succeeded except alum. The doses of alum and sulphate of iron may be varied. The more alum you add the paler will be the color. Three parts of alum to one of sulphate of iron give a color which approaches a flesh-color. It is alum also which gives this color the property of becoming fixed at a very strong heat. This color may be employed on raw enamel; it has much more fixity than the purple, but not so much as the blue of cobalt. It may be washed to carry off the superfluous saline matter, but it may be employed also without edulcoration; in that state it is even more fixed and more beautiful. It does not require much flux; the flux which appeared to me to be best suited to it is composed of alum, minium, marine salt, and enamel sand. This flux must be compounded in such a manner as to render it sufficiently fusible for its objects: from two or three parts of it are mixed with the color. In general three parts of flux are used for one of color; but this dose may, and ought to be varied, according to the nature of the color and the shade of it required. Red calx of iron alone, when it enters into fusion with glass, gives a color which seems to be black; but if the color be diluted with a sufficient quantity of glass, it at last becomes of a transparent yellow. Thus the color really produced by calx of iron combined with glass is a yellow color, but which being accumulated becomes so dark, that it appears black. In the process above given for making the red color, oxide of iron does not fuse; and this is the essential point; for, if this color is carried in the fire to vitrification, it becomes black or yellowish, and disappears if the coat be thin, and the oxide of iron present be only in a small quantity.

Yellow.—Though yellow may be obtained in a direct manner, compound yellows are preferred because they are more certain in effect, and more easily applied, than the yellow which may be directly obtained from silver. The compound yellows are obtained in consequence of the same principles as the red color of iron. For this purpose we employ metallic oxides, the vitrification of which must be prevented by mixing with them other substances, such as refractory earths or metallic oxides difficult to be fused. The metallic calces which form the basis of the yellow colors are generally those of lead; as minium, the white calx of lead, or litharge, the white calx of antimony, called diaphoretic antimony; that called crocus metallorum is also employed. This regulus pulverised, and mixed with white oxide, gives likewise a yellow. The following are the different compositions used: one part of the white oxide of antimony, one part of the white oxide of lead, or two or three; these doses are exceedingly variable; one part of alum and one of sal-ammoniac. When these matters have been all pulverised and mixed well together they are put in a vessel over a fire sufficient to sublimate and decompose the sal-ammoniac; and when the matter has assumed a yellow color the operation is finished. The calces of lead mixed in a small quantity either with silex or alumine, also with the pure calx of tin, exceedingly white, gives likewise yellows. One part of th oxide of lead is added to two, three, or four of the other substances above mentioned. In these different compositions for yellow you may use also oxide of iron, either pure or that kind which has been prepared with alum and vitriol of iron; you will then obtain different shades of yellow. From what has been said, you may vary these compositions of yellow as much as you please. Yellows require so little flux that one or two parts, in general, to one of the color are sufficient. Saline fluxes are improper for them, and especially those which contain nitre. They must be used with fluxes composed of enamel-sand, oxide of lead, and borax, without marine salt. A yellow may be obtained also directly from silver. All these mixtures may be varied, and you may try others. For this purpose you may use sulphate of silver, or any oxide of that metal mixed with alumine or silex, or even with both in equal quantities. The whole must be gently heated until the yellow color appears, and the matter is to be employed with the fluxes pointed out for yellow. Yellow of silver, like purple, cannot endure a strong heat; a nitric solution of silver may be precipitated by the ammoniacal phosphate of soda, and you will obtain a yellow precipitate which may be used to paint in that

color with fluxes, which ought then to be a little harder. Besides the methods above mentioned, the best manner of employing the oxide of silver is, in my opinion, to employ it pure: in that case you do not paint but stain. It will be sufficient then to lay a light coating on the place which you wish to stain yellow, and to heat the article gently to give it the color. You must not employ too strong a heat: the degree will easily be found by practice. When the article has been sufficiently heated, you take it from the fire and separate the coating of oxide, which will be found reduced to a regulus. You will then observe the place which it occupied tinged of a beautiful yellow color without thickness. It is chiefly on transparent glass that this process succeeds best. Very fine silver filings produce the same effect: but what seemed to succeed best in this case was sulphate of silver well ground up with a little water, that it may be extended very smooth. From what has been said, it may readily be seen that this yellow must not be employed like other colors; that it must not be applied till the rest have been fused; for, as it is exceedingly fusible and ready to change, it would be injured by the other colors; and as the coating of silver, which is reduced, must be removed, the fluxes would fix it, and prevent the possibility of its being afterwards separated. Working on glass is not attended with this inconvenience, because the silver yellow is applied on the opposite side to that on which the other colors are laid.

GREEN.—Green is obtained directly from the oxide of copper. All the oxides of copper are good; they require little flux, which even must not be too fusible: one part or two of the flux will be sufficient for one oxide. This color agrees with all the fluxes, the saline as well as the metallic, which tends to vary a little the shades. A mixture of yellow and blue is also used to produce greens. Those who paint figures or portraits employ glass composed in this manner; but those who paint glazed vessels, either earthenware or porcelain, employ, in general, copper green. Independently of the beautiful green color produced by oxidated copper, it produces also a very beautiful red color. This beautiful red color produced by copper, is exceeding fugitive. The oxide of copper gives red only when it contains very little oxygen, and approaches near to the state of a regulus. Notwithstanding the difficulty of employing this oxide for a red color, a method has been found to stain transparent glass with different shades of a very beautiful red color by means of calx of copper. The process is as follows: you do not employ the calx of copper pure, but add to it calx of iron, which, for that purpose, must not be too much calcined; you add also a very small quantity of calx of copper to the mass of glass which you are desirous of tinging. The glass at first must have only a very slight tinge of green, inclining to yellow. When the glass has that color you make it pass to red, and even a very dark red, by mixing with it red tartar in powder, or even tallow. You must mix this matter well in the glass, and it will assume a very dark red color. The glass swells up very much by this addition. Before it is worked it must be suffered to settle, and become compact; but as soon as it has fully assumed the color it must be immediately worked, for the color does not remain long, and even often disappears while working; but it may be restored by heating the glass at the flame of a lamp. It is difficult to make this color well, but when it succeeds it is very beautiful, and has a great deal of splendor. By employing the calx of copper alone, for the processes above mentioned, you will obtain, when you succeed well, a red similar to the most beautiful carmine. The calx of iron changes the red into vermilion, according to the quantity added. If we had certain processes for the making of this color, we should obtain all the shades of red from pure red to orange, by using, in different proportions, the oxide of copper and that of iron. The calx of copper fuses argil more easily than silex: the case is the same with calx of iron. If you fuse two or three parts of argil with one of the oxide of copper, and if the heat be sufficient, you will obtain a very opaque enamel, and of vermilion red color. The oxide of copper passes from red to green, through yellow, so that the enamel of copper, which becomes red at a strong heat, may be yellow with a weaker heat. The same effect may be produced by deoxidating copper in different degrees: this will be effected according as the heat is more or less violent. The above composition might, I think, be employed to give a vermilion red color to porcelain. The heat of the porcelain furnace ought to be of sufficient strength to produce the proper effect. The calx of iron fused also with argil, in the same proportions as the calx of copper, gives a very beautiful black. These porportions may, however, be varied.

BLUE.—Blue is obtained from the oxide of cobalt. It is the most fixed of all colors, and becomes equally beautiful with a weak as with a strong heat. The blue produced by cobalt is more beautiful the purer it is, and the more it is oxidated. Arsenic does not hurt it. The saline fluxes which contain nitre are those best suited to it: you add a little also when you employ that flux which contains a little calcined borax, or glass of borax, though you may employ it also with that flux alone. But the flux which, according to my experiments, gives to cobalt-blue the greatest splendor and beauty is that composed of white glass, which contains no metallic calx, of borax, nitre, and diaphoretic antimony well washed. When this glass is made for the purpose of being employed as a flux for blue, you may add less of the white oxide of antimony: a sixth of the whole will be sufficient.

VIOLET.—Black calx of manganese, employed with white fluxes, gives a very beautiful violet. By varying the fluxes the shade of the color may also be varied. It is very fixed as long as it retains its oxygen. The oxide of manganese may produce different colors; but for that purpose it will be necessary that we should be able to fix its oxygen in it in different proportions. How to effect this has, perhaps, never yet been discovered. These are all the colors obtained from metals. From this it is evident that something still remains to be discovered. We do not know what might be produced from the oxides of platina, tungsten, molybdena, and nickel: all these oxides are still to be tried; each of them must produce a color, and perhaps red, which is obtained

neither directly nor with facility from any of the metallic substances formerly known and hitherto employed.

Having laid before the English artists the result of M. Clouet's Researches, as they were presented to the French National Institute, of which he was an associate, we add a few general observations taken from those of our own countrymen, who have made the subject of enamelling their study and employment. The most beautiful and expensive color known in this branch of the art is an exquisitely fine, rich, and purplish tinge, given by the salts and oxides of gold, especially the purple precipitate formed by tin in one form or other, and the nitro-muriate of gold, and also by fulminating gold. This fine color, however, requires much skill in the artist to be fully brought out. Other and commoner reds are given by the oxides of iron, but this requires the mixture of alumine, or some other substance refractory in the fire; otherwise what would, under proper circumstances, be a full red will degenerate into a black.

Yellow is either given by the oxide of silver alone, or by the oxides of lead and antimony, with similar mixtures to those required with iron. The silver is as tender a color as gold, and as readily injured or lost in a high heat. Green is given by the oxide of copper, or it may also be produced by a mixture of yellow colors. Blue is given by cobalt, and this seems the most certain of all enamel colors, and as easy to be managed. Black is produced by a mixture of cobalt and manganese. 'The reader,' says Mr. Aikin in his Chemical Dictionary, 'may conceive how much the difficulties of this nice art are increased, when the object is not merely to lay a uniform colored glazing on a metallic surface, but also to paint that surface with figures and other designs that require extreme delicacy of outline, accuracy of shading, and selection of coloring. The enamel painter has to work, not with actual colors, but with mixtures which he knows from experience, will produce certain colors after the operation of the fire; and to the common skill of the painter in the arrangement of his pallet, and the choice of his colors, the enameller has to add an infinite quantity of practical knowledge of the chemical operation of one metallic oxide on another, the fusibility of his materials, and the utmost degree of heat at which they will attain not only the accuracy of the figures which he has given, but the precise shade of color which he intends to lay on. Painting in enamel requires a succession of firings; first, of the ground which is to receive the design, and which itself requires two firings, and then of the different parts of the design itself. The ground is laid on in the same general way as the common watch-face enamelling already described. The colors are the different metallic oxides melted with some or other vitrescent mixture, and ground to extreme fineness. These are worked up with an essential oil, that of spike is preferred, and next to it the oil of lavender, to the proper consistence of oil colors, and are laid on with a very fine hair brush. The essential oil should be very pure, and by the use of this, rather than any fixed oil, it is probable that the whole may evaporate completely in a moderate heat, and leave no carbonaceous matter in contact with the color when red-hot, which might affect its degree of oxidation, and thence the shade of color which it is intended to produce. As the color of some of the vitrified metallic oxides, such as that of gold, will stand only at a moderate heat, while others will bear and even require a higher temperature to be properly fixed, it forms a great part of the technical skill of the artist to apply different colors in their proper order; fixing first those shades which are produced by the colors that will endure the highest degree of heat. The outline of the design is first traced on the enamel ground, and burnt in; after which the parts are filled up gradually with repeated burnings to the last and finest touches of the tenderest enamel.'

Those who paint on enamel, on earthenware, porcelain, &c., must regulate the fusibility of the colors by the most tender of those employed, as, for example, the purple. When the degree which is best suited to purple has been found, the other less fusible colors may be so regulated (by additions of flux), when it is necessary to fuse all the colors at the same time, and at the same degree of heat. You may paint also in enamel without flux; but all the colors do not equally stand the heat which must be employed. If the enamel, however, on which you paint be very fusible, they may all penetrate it. This manner of painting gives no thickness of color; on the contrary, the colors sink into the enamel at the places where the tints are strongest. To make them penetrate, and give them lustre, a pretty strong fire will be necessary to soften the enamel, and bring it to a state of fusion. This method cannot be practised but on enamel composed with sand, which is called enamel-sand, as already mentioned. It may be readily seen, also, that the colors and enamel capable of enduring the greatest heat will be the most solid, and the least liable to be changed by the air.

The following method of filling up engraving on silver with a durable black enamel, is practised in Persia and India:—

They take half an ounce of silver, two ounces and a half of copper, three ounces and a half of lead, twelve ounces of sulphur, two ounces and a half of sal-ammoniac. The metals are melted together, and poured into a crucible, which has been before filled with pulverised sulphur, made into a paste by means of water; the crucible is then immediately covered, that the sulphur may not take fire, and this regulus is calcined over a smelting-fire, until the superfluous sulphur be burned away. This regulus is then coarsely pounded, and, with a solution of sal-ammoniac, formed into a paste, which is rubbed into the engraving on silver plate. The silver is then wiped clean, and suffered to become so hot under the muffle, that the substance rubbed into the strokes of the engraving melts and adheres to the metal. The silver is afterwards wetted with the solution of sal-ammoniac, and again placed under the muffle till it becomes red-hot. The engraved surface may then be smoothed and polished without any danger of the black substance, which is an artificial kind of silver ore,

either dropping out, or decaying. In this manner is all the silver-plate brought from Russia ornamented with black engraved figures.

The town of Limoges was very celebrated in the twelfth and thirteenth centuries for the excellence of its enamels on various metals. In 1197, tables, vases, basins, tabernacles, candelabra, crosiers, &c., enriched with enamels, were called opus de Limogia, labor Limogiæ, opus Lemoviticum, and are still known to dealers in curiosities of this nature as enamels of Limoges.

The principal artists who have excelled in this beautiful department of the fine arts are Primaticcio and Maitre Roux, who introduced a pure taste in arabesques, and other pictorial ornaments, which were beautifully executed in enamel. Raffaelle and Michel Angiolo also gave designs for enamels on porcelain and earthenware, many of which are still called Raffaelle's ware, or china. Enamelling on metal is of later invention, and is attributed to the French, particularly the smaller and more elegant subjects of history, poetry, and fancy. The first artist who distinguished himself in this latter department, and, in fact, as its inventor, was Jean Toutin, a goldsmith at Chateaudun. He was succeeded by his disciple Gribelin, who was also an excellent artist and workman. Dubie, a goldsmith, made excellent enamels in the galleries of the Louvre. Morliere, a native of Orleans, but who practised at Blois, followed soon after; and was much admired for his miniature enamels for rings and watch-cases. He had for a disciple Robert Vauquer of Blois, who surpassed all his predecessors, particularly in his coloring; he died in 1670. Pierre Chartier, also of Blois, was a celebrated enamellist, particularly in flowers. Jean Petitot, who died in 1691, succeeded as an enamelist of high repute, and practised in England, where his works are well known, and deservedly admired. Bordier followed in the same line, and also practised in this country; as did Louis Hance and Louis de Guernier. Zinck, a Swede, has also obtained a high reputation for the excellence of his works; as did an artist of the name of Boit, whose character as an artist is given in Walpole's Anecdotes of Painters. One of his enamels is there mentioned as being of the extraordinary dimensions of twenty-two inches by sixteen; which have, however, been exceeded by our native artists Bone and Muss. We have also to notice, as eminent practitioners in this art, Schnell, who died in 1704; Sophia Cheron, in 1711; Chatillon, in 1732; Ism. Mengs, in 1764; Nelson, in 1770; Meytens, a Swede, in 1770; Rouquet, who practised in England, and wrote upon the arts; Liotard, Duran, Paguier.

ENAM'OUR, *v. a.* } Span. and Port. *enamorar*; Ital. *inamorare*,
ENAM'ORADO. } from en and AMOUR, which see. To inspire or inflame with love; taking *of* before the object. But Milton and Shakspeare use it without; an enamorado is one desperately in love.

An *enamorado* neglects all other things to accomplish his delight. *Sir T. Herbert.*

Affliction is *enamoured of* thy parts,
And thou art wedded to calamity. *Shakspeare.*

You are very near my brother in his love: he is *enamoured* on Hero. *Id.*

Or should she, confident,
As sitting queen adored on beauty's throne,
Descend with all her winning charms begirt,
To *enamour*, as the zone of Venus once
Brought that effect on Jove, so fables tell. *Milton.*

He, on his side,
Leaning half-raised, with looks of cordial love
Hung over her *enamoured*. *Id. Paradise Lost.*

Your uncle cardinal
Is not so far *enamoured of* a cloyster,
But he will thank you for the crown. *Dryden.*

Strange fondness of the human heart,
*Enamoured* of its harm!
Strange world, that costs it so much smart,
And still has power to charm. *Cowper.*

Various and strange was the long-winded tale;
And halls, and knights, and feats of arms displayed;
Or merry swains, who quaff the nut-brown ale,
And sing *enamoured* of the nut-brown maid. *Beattie.*

ENARRA'TION, *n. s.* Lat. *enarro.* Explanation; exposition.

I might further yet confirm this truth by an anatomical *enarration* of the several compounding parts of these limbs. *Smith on Old Age.*

ENARTHRO'SIS, *n. s.* Ἐν and ἄρθρον. The insertion of one bone into another to form a joint.

*Enarthrosis* is where a good round head enters into a cavity, whether it be a cotyla, or profound cavity; as that of os coxæ, receiving the head of the os femoris; or glene, which is more shallow, as in the scapula, where it receives the humerus. *Wiseman.*

ENARTHROSIS, in anatomy, is a species of Diarthrosis. See ANATOMY.

ENA'UNTER, *adv.* An obsolete word, explained by Spenser himself, to mean lest that.

Anger would not let him speak to the tree,
*Enaunter* his rage might cooled be,
But to the root bent his sturdy stroke. *Spenser.*

ENAS'CENT, *adj.* } From *e*, and nascent;
ENATE'. } Lat. *nascor*, *nascens*, rising; springing or rising forth.

The parts appertaining to the bones, which arise out at a distance from their bodies, are either the adnate or *enate* parts. *Smith on Old Age.*

Thus when in holy triumph Aaron trod,
And offered on the shrine his mystic rod;
First a new bark its silken tissue weaves,
New buds emerging widen into leaves;
Fair fruits protrude, *enascent* flowers expand,
And blush and tremble round the living wand. *Darwin.*

ENCA'GE, *v. a.* From en and cage. To shut up in a cage; to coop up; to confine.

He suffered his kinsman March,
Who is, if every owner were right placed,
Indeed his king, to be *encaged* in Wales,
There, without ransom, to lie forfeited. *Shakspeare.*

Like Bajazet *encaged*, the shepherd's scoff,
Or like slack-sinewed Sampson, his hair off. *Donne.*

ENCAMP', *v. n.* } Fr. *camper*. From
ENCAMP'MENT. *n. s.* } en and CAMP, which see. To pitch tents, or form a camp: hence, to settle or dwell for a time.

He *encamped* at the mount of God. *Exod.* xiii. 5.

Their enemies served to improve them in their *encampments*, weapons, or something else. *Grew.*

When a general bids the martial train
Spread their *encampment* o'er the spacious plain,
Thick rising tents a canvas city build.
*Gay's Trivia.*

A feudal kingdom was properly the *encampment* of a great army; military ideas predominated, military subordination was established.
*Robertson. History of Scotland.*

Among the regulations concerning encampment, published in Britain by authority, the following are particularly to be attended to. 'On the arrival of a brigade, or a battalion, on the ground destined for its camp, the quarter and rear guards of the respective regiments will immediately mount; and, when circumstances require them, the advanced picquets will be posted. The grand guards of cavalry will be formed, and the horses picketed. The men's tents will then be pitched, and, till this duty is completed, the officers are on no account to quit their troops or companies, or to employ any soldier for their own accommodation. Necessaries are to be made in the most convenient situations, and the utmost attention is required in this, and every other particular, to the cleanliness of the camp. If circumstances will allow the ground on which a regiment is to encamp to be previously ascertained, the pioneers should make these, and other essential conveniences, before the corps arrives at its encampment. Whenever a regiment remains more than one night in a camp, regular kitchens are to be constructed. No tents, or huts, are to be allowed in front, or between the intervals of the battalions. A spot of ground for this purpose should be marked out by the quarter-master, with the approbation of the commanding officer. On arriving in a camp which is intersected by hedges, ditches, unequal or boggy ground, regiments will immediately make openings of communication, of sixty feet in width. The ground in front of the encampment is to be cleared, and every obstacle to the movement of the artillery and troops is to be removed. Commanding officers of regiments must take care that their communication with the nearest grand route is open and free from impediments.' The arrangement of tents in a camp is nearly the same all over Europe; which is, to dispose them in such a manner, that the troops may form with safety and expedition. To answer this end, the troops are encamped in the same order as that in which they are to engage the enemy, which is by battalions and squadrons; hence, the post of each battalion and squadron must necessarily be at the head of its own encampment. Gustavus Adolphus, king of Sweden, was the first who formed encampments according to the order of battle. By this disposition the extent of the camp, from right to left of each battalion and squadron, will be equal to the front of each in line of battle; and consequently, the extent from right to left, of the whole camp, should be equal to the front of the whole army when drawn up in line of battle, with the same intervals between the several encampments of the battalions and squadrons, as are in the line. Each regiment posts a subaltern's guard at eighty yards from the colors to the officer's tent, called the quarter-guard; besides a corporal's guard in the rear, called the rear-guard. Each regiment of horse or dragoons has also a small guard on foot, called the standard-guard, at the same distance. The grand guard of the army consists of horse, and is posted about a mile or a mile and a half distance towards the enemy. In a siege, the camp is placed all along the line of circumvallation, or rather in the rear of the approaches, out of cannon-shot. The army faces the circumvallation, if any, that is, the soldiers have the town in their rear. It is of great consequence, that a camp have a commodious spot of ground at its head, where the army, in case of surprise, may in a moment be under arms, and in a condition to repulse the enemy; as also, that there be a convenient field at a small distance, and of a sufficient extent to form in advantageously, and move with facility.

ENCANTHIS, in surgery, a tubercle arising either from the caruncula lachrymalis, or from the adjacent red skin; sometimes so large, as to obstruct not only the puncta lachrymalia, but also part of the sight or pupil itself. See SURGERY.

ENCARPIA, Gr. εγκαρπια, in architecture, flower-work, or fruit-work, on the corners of pillars.

ENCA'VE, *v. a.* From en and cave. To hide as in a cave.

Do but *encave* yourself,
And mark the fleers, the gibes, and notable scorns,
That dwell in ev'ry region of his face;
For I will make him tell the tale anew.
*Shakspeare.*

ENCAUSTIC PAINTING, Lat. *encausticus*; Gr. Ἐγκαυστική. The art of painting in encaustic is a manner of painting which is executed with the operation of fire. Ancient authors often make mention of this species of painting, and which, if it had been described simply by the word encaustic, which signifies executed by fire, might be supposed to have been a species of enamel painting. But the expressions encausto pingere, pictura encaustica, ceris pingere, picturam inurere, by Pliny and other ancient writers, make it clear another species of painting is thereby meant. We have no ancient pictures of this description, and therefore the precise manner adopted by the ancients is not completely developed, though many moderns have closely investigated the subject, and described their processes. At what time, and by whom, this species of painting was first invented, is not determined by antiquaries, although it appears to have been practised in the fourth and fifth centuries. Count Caylus and M. Bachelier, a painter, were the first of modern times who made experiments in this branch of art, about the year 1749. Some years after this, Count Caylus presented to the Academy of Painting at Paris his ideas and experiments on the subject of the ancient manner of painting in encaustic. In 1754 the count had a head of Minerva painted by M. Vien, after the process described by himself, and presented it to the Academy of Sciences in 1755. This success induced M. Bachelier to recommence his experiments, in which he suc-

ceeded better than formerly; but his manner of painting in encaustic differed from the ancients, as described by Pliny, and therefore he was unsuccessful, inasmuch as he did not discover the real ancient manner; after this he made some other experiments on the same subject, differing from the process as described by Caylus and others.

Pliny, in a passage relating to encaustic painting, distinguishes three species:—1st, that in which they used a style, and painted on ivory or polished wood (cestro in ebore); for which purpose they drew the outlines on a piece of the aforesaid wood or ivory, previously soaked or imbued with some certain color; the point of the style or stigma served for this operation, and the broad end to scrape off the small filaments that arose from the outlines, and they continued forming outlines with the point till they were finished. 2nd. The next manner appears to have been, where the wax previously impregnated with color was spread over the surface of the picture with the style, and the colors thus prepared were formed into small cylinders for use. By the side of the painter was a brasier for keeping the styles continually hot, with the points of which they laid on the colors when the outlines were finished, and spread them smooth with the broad end, and thus they proceeded till the picture was finished. 3rd. The manner was by painting with a pencil in wax liquefied by fire: by this method the colors contained a considerable hardness, and could not be damaged either by the heat of the sun or the deleterious effects of sea water. It was thus that they painted their ships with emblems and other pictures, and therefore it obtained the name of ship-painting. The last process was to smooth and polish the picture;—thus far the ancients.

Few of late years have made more experiments in this mode of painting than the ingenious Mrs. Hooker of Rottingdean, in the county of Sussex, who has, in this instance, united practice with theory; and, for her very successful exertions in this branch of the polite arts, was presented with a gold palette by the Society for the Encouragement of Arts, &c., of London. Her account is printed in the tenth volume of the Society's Transactions for the year 1792, when Miss Emma Jane Greenland. Her first communication with specimens of this mode of painting was made in the year 1786, one of which is preserved in the Society's rooms at the Adelphi, and is worth the attention of the artist. This honorable testimony of the society's approbation did not occasion any relaxation in this indefatigable lady's endeavour to attain excellence, and she therefore, in the year 1807, made a farther communication to the Society of the result of no less than fifty experiments per day, during more than four months; and to theory Mrs. Hooker has added much practical knowledge, having painted several pictures very successfully. The following account combines the results of this lady's two communications to the Society, which, in honor to her extraordinary merits and exertions in this curious branch of the fine arts, should be called the Hookerian mode of encaustic painting.

Method of preparing and applying a composition for painting, in imitation of the ancient Grecian manner, as practised by Mrs. Hooker: —Put into a glazed earthen vessel four ounces and a half of gum arabic, and eight ounces or half a pint (wine measure) of cold spring water: when the gum is dissolved, stir in seven ounces of gum mastich, which has been washed, dried, picked, and beaten fine. Set the earthen vessel containing the gum, water, and gum mastich, over a slow fire, continually stirring and beating them hard with a spoon, in order to dissolve the gum mastich: when sufficiently boiled it will no longer appear transparent, but will become opaque and stiff like a paste. As soon as this is the case, and the gum, water, and mastich are quite boiling, without taking them off the fire, add five ounces of white wax, broken into small pieces, stirring and beating the different ingredients together till the wax is perfectly melted and has boiled; then take the composition off the fire, as boiling it longer than necessary would harden the wax, and prevent its mixing so well afterwards with water. When the composition is taken off the fire, and in the glazed earthen vessel, it should be beaten hard, and whilst hot (but not boiling) mix with it by degrees a pint (wine measure) or sixteen ounces more of cold spring water; then strain the composition as some dirt will boil out of the gum mastich, and put it into bottles. The composition, if properly made, should be like a cream, and the colors, when mixed with it, as smooth as with oil. The method of using it is to mix with the composition, upon an earthen palette, such colors in powder as are used in painting with oil, and such a quantity of the composition to be mixed with the colors as to render them of the usual consistency of oil colors, then paint with fair water.

The colors, when mixed with the composition, may be laid on either thick or thin, as best suits your subject, on which account this composition is very advantageous where any particular transparency of coloring is required; but in most cases it answers best if the colors are laid on thick, as they require the same use of the brush as if painting with body colors, and the same brushes as used in oil painting. The colors, if grown dry when mixed with the composition, may be used by putting a little water over them; but it is less trouble to put some water when the colors are observed to be growing dry. In painting with this composition the colors blend without difficulty when wet, and even when dry the tints may easily be united by means of a brush and a very small quantity of water. When the painting is finished, put some white wax into a glazed earthen vessel over a slow fire, and when melted, but not boiling, with a hard brush cover the painting with the wax, and when cold take a moderately hot iron, such as is used for ironing linen, and so cold as not to hiss if touched with any thing wet, and draw it lightly over the wax. The painting will appear as if under a cloud till the wax and whatever substance the picture is painted upon are perfectly cold; but if when so the painting should not appear sufficiently clear, it may be held before the fire at such a distance as to melt the wax slowly; or the wax may be

melted by holding a hot poker at such a distance as to melt it gently, especially over such parts of the picture as should not appear sufficiently transparent or brilliant: for the oftener heat is applied to the picture the greater will be the transparency and brilliancy of coloring; but the contrary effect would be produced if too sudden or too great a degree of heat is applied, or for too long a time, as it will draw the wax too much to the surface, and may likewise crack the paint. Should the coat of wax put over the painting when finished appear in any part uneven, it may be remedied by drawing a moderately hot iron over it again as before mentioned, or even by scraping the wax with a knife; and should the wax, by too great or too long an application of heat, form into bubbles at particular places, by applying a poker heated, or even a tobacco pipe made hot, the bubbles will subside; or such defects may be removed by drawing any thing hard over the wax, which will close any small cavities. When the picture is cold rub it with a fine linen cloth. Paintings may be executed in this manner upon wood, having first pieces of wood let in behind, across the grain of the wood, to prevent its warping, canvas, card, or plaster of Paris. The plaster of Paris requires no other preparation than mixing some fine plaster of Paris in powder with cold water the thickness of cream; then put it on a looking-glass, having first made a frame of bees'-wax on the looking-glass, the form and thickness of which you wish the plaster of Paris to be, and when dry take it off, and there will be a very smooth surface to paint upon. Wood and canvas are best covered with some gray tint mixed with the same composition of gum arabic, gum mastich, and wax, and of the same sort of colors as before mentioned, before the design is begun, in order to cover the grain of the wood, or the threads of the canvas. Painting also may be done in the same manner with only gum water and gum mastich prepared the same way as the mastich and wax; but instead of putting seven ounces of mastich, and, when boiling, adding five ounces of wax, mix twelve ounces of gum mastich with the gum water, prepared as mentioned in the first part of this receipt: before it is put on the fire, and when sufficiently boiled and beaten, and a little cold, stir in by degrees twelve ounces, or three-quarters of a pint, wine measure, of cold spring water, and afterwards strain it. It would be equally practicable to paint with wax alone, dissolved in gum water in the following manner. Take twelve ounces, or three-quarters of a pint, wine measure, of cold spring water, and four ounces and a half of gum arabic, put them into a glazed earthen vessel, and, when the gum is dissolved, add eight ounces of white wax. Put the earthen vessel, with the gum water and wax, upon a slow fire, and stir them till the wax is dissolved and has boiled a few minutes; then take them off the fire, and throw them into a basin, as by remaining in the hot earthen vessel the wax would become rather hard; beat the gum water and wax till quite cold. As there is but a small proportion of water, in comparison to the quantity of gum and wax, it would be necessary, in mixing this composition with the colors, to put also some fair water. Should the composition be so made as to occasion the ingredients to separate in the bottle, it will become equally serviceable if shaken before used to mix the colors.

Another very serviceable quality in the vehicle for painting was discovered by Mrs. Hooker, which was, that the composition which had remained in a bottle since the year 1792, in which time it had grown dry and become as solid a substance as wax, returned to a cream-like consistence, and became again in as proper a state to mix with colors as when it was first made, by putting a little cold water upon it, and suffering it to remain on a short time. 'I also lately found,' says this ingenious lady, 'some of the mixture composed of only gum arabic water and gum mastich, of which I sent a specimen to the Society of Arts in 1792; it was become dry, and had much the appearance and consistency of horn. I found, on letting some cold water remain over it, that it became as fit for painting with as when the composition was first prepared.'

J. Chr. Werner, of Newstadt, in Germany, found the following process very effectual in making wax soluble in water:—For each pound of white wax he takes twenty-four ounces of potassa, which he dissolves in two pints of water, warming it gently. In this lie he boils the wax, cut into little bits, for half an hour; at the end of this time he takes it from the fire and lets it cool. The wax fixes itself at the surface of the liquor in the form of a white saponaceous matter, which, being triturated with water, produces a sort of emulsion which he called wax milk, or encaustic wax, and may be applied to pictures, furniture, or leather, after having well cleaned them: in an hour after the application the article should be rubbed with a piece of woollen cloth, which will cause the pictures to have a better effect, and the furniture to acquire a peculiar brightness. Another advantage of this preparation of wax is, that it can be mixed with all kinds of colors, and consequently be applied in a single operation. It is also useful to fix water colors.

The following important observations are translated from the Italian of the chevalier Lorgna, who has deeply investigated the subject, in a small but valuable tract called, Un Discorso sulla Cera Punica. The ancients, says this author, according to Pliny, used three species of painting, and in all three they used fire; so that to paint with encaustic, or with a burning application, abbrucciamento, is derived from a Greek word.

We have never thoroughly known the nature of the Punic wax, which was anciently used, and which, after all, was the essential ingredient of the ancient painting in encaustic. The chevalier praises the genius and industry of M. Requeno and M. Bachelier, who have also treated this subject, but who have not fully succeeded in finding out the true way of making the said wax, then quotes the passage of Pliny on the method of making it, Punica fit hoc modo, &c. see Pliny's Nat. Hist. l. 21, c. 14, and asserts, with many other writers, that Pliny's nitre is not the nitre of the moderns, properly so called, but it

is the natron of the ancients, viz. the native salt which is found crystallised in Egypt and other hot countries, in sands surrounding lakes of salt water; it must not be mistaken for the natron of the new nomenclature of our college of physicians, which is the new name of the mineral alkali.

In the plains of Lower Egypt, which were once covered by the sea, in the environs of the salt lakes of that country, at Tripoli, at Tunis, as also in the adjacent parts of ancient Carthage, the natron, that same natron which, under the name of nitre, the Carthagin ans, according to Pliny, used in preparing their wax, is to this day extracted, and hence it was called Punic wax.

I began now, says Lorgna, successively to try my experiments, first with three parts of wax and one of natron, and then with four of wax, and so on till I used twenty parts of white melted wax with one only of natron, with as much water as was just sufficient to melt the natron. I held the mixture in an iron vessel over a slow fire, stirring it gently with a wooden spatula, till the two substances thickened by evaporation, and, in closely uniting, the mass by degrees assumed the consistence of butter, and the color of milk. I removed it then from the fire, and put it in the shade to let it harden, and to perfect itself in the open air. This natron was extracted from the lie of kali of Malta, evaporated till it was dry; it may also be extracted from the kali of Spain, Sicily, Sardinia, and from that of Tunis and of Tripoli, which may be procured without much difficulty. The wax being cooled it liquefied in water, and a milky emulsion resulted from it like that which could be made with the best Venetian soap.

Pliny, in another place, c. 7, l. 23, gives further directions for the manner of using caustic on paintings on walls; but, as it concerns the antiquary more than the artist, I have forborne from making the quotation. It begins at these words, 'Ut parietis siccato cera Punica,' &c.

As to making use of this wax in painting in encaustic the chevalier says, that magnificent and repeated experiments were made in the apartments of the Count Giovanni Battista Gasola, by the Italian painter Signor Antonio Paccheri. He dissolved the Punic wax, when it was not yet so much hardened as to require to be igni resoluta, as expressed by Pliny, with pure water lightly infused with gum arabic, instead of sarcocolla, male incense, mentioned by Pliny. He afterwards melted and mixed his colors with this wax so liquefied as he would have done with oil, and proceeded to paint in the same manner; nor were the colors seen to run or alter in the least; and the mixture was so flexible that the pencil ran smoother with it than it would have done with oil. The painting being dry, he used the caustic over it, and rubbed it with linen cloths, by which the colors acquired a peculiar vivacity and brightness which they had not before the caustic and the rubbing had been effected.

ENCEINTE, *n. s.* Fr. *enceinte*; Lat *incingo*, to enclose. In fortification, is the interior wall or rampart which surrounds a place, sometimes compos d of bastions or curtains, either faced or lined with brick or stone, or only made of earth. See ENSIENT.

The *enceinte* is sometimes only flanked by round or square towers, which is called a Roman wall. *James.*

ENCEN'IA, *n. s.* plural. Gr. εγκαινια (καινος, new). Festivals in celebration of the founding of certain temples or public places. See the following article.

Besides those verses in the Oxford books, which he could not help setting his name to, several of his compositions came abroad under other names. The *Encænia*, and public Collections of the University upon State Subjects, were never in such esteem, either for elegy or congratulation, as when he contributed most largely to them. *Johnson's Life of Smith.*

ENCENIA. These were festivals anciently kept in honor of the building of certain cities or great towns. The Jews kept one on the day on which the temple was dedicated, and the Christians thus celebrated the consecration of their churches. At Oxford it has signified in modern times the ceremonies and solemnities instituted in honor of founders or benefactors of colleges.

ENCHA'FE, *v. a.* Fr. *eschauffer*. To enrage; to irritate; to provoke.

The wind-shaked surge, with high and monstrous main,
Seems to cast water on the burning bear,
I never did like molestation view
On the *enchafed* flood. *Shakspeare. Othello.*

ENCHAIN'. Fr. *enchainer*, from en and CHAIN, which see. To chain or fasten together: hence, to bind; hold under power; subject.

The one contracts and *enchains* his words, speaking pressingly and short; the other delights in long-breathed accents. *Howel.*

What should I do! while here I was *enchained*,
No glimpse of god-like liberty remained. *Dryden.*

ENCHANT', *v. a.*
ENCHANT'ER, *n. s.*
ENCHANT'ING, *adj.*
ENCHANT'INGLY, *adv.*
ENCHANT'MENT, *n. s.*
ENCHANT'RESS, *n. s.* fem.

Fr. *enchanter*; Span. *encantar*; Ital. and Lat. *incantare*, from *in* and *canto*, to sing, because magical charms were often composed in verse, and sung by the enchanter. To influence or subdue by charms or spells: hence, to delight extremely; to enrapture; the derivations all follow one or other of these senses.

The Turks thought that tempest was brought upon them by the charms and *enchantments* of the Persian magicians. *Knolles.*

And now about the cauldron sing,
Like elves and fairies in a ring,
*Enchanting* all that you put in. *Shakspeare.*
Fell banning hag! *enchantress*, hold thy tongue. *Id.*

One whom the music of his own vain tongue
Doth ravish like *enchanting* harmony. *Id.*

He's gentle; never schooled, and yet learned, full of noble device; of all sorts *enchantingly* beloved. *Id.*

If the king had not been persuaded of the strength of his charm, he had not sent so far, and paid so dear for it; now he trusts more to his *enchantment*, than to the forces of Moab and Midian. *Bp. Hall. Contemplations.*

These powerful drops thrice on the threshold pour,
And bathe with this *enchanted* juice her door;

That door where no admittance now is found,
But where my soul is ever hovering round. *Gran.*

Arcadia was the charmed circle, where all his spirits for ever should be *enchanted*. *Sidney.*

From this *enchantress* all these ills are come ;
You are not safe 'till you pronounce her doom. *Dryden.*

I have it by certain tradition, that it was given to the first who wore it by an *enchantress*. *Tatler.*

Such phasms, such apparitions, are excellencies which men applaud in themselves, conjured up by the magick of a strong imagination, and only seen within that circle in which the *enchanter* stands. *Decay of Piety.*

Gladio, by valour and stratagem, put to death tyrants, *enchanters*, monsters, and knights. *Spectator.*

John thinks them all *enchanted* : he enquires if Nick had not given them some intoxicating potion. *Arbuthnot.*

Warmth of fancy will carry the loudest and most universal applause, which holds the heart of a reader under the strongest *enchantment*. *Pope.*

Too dear I prized a fair *enchanting* face ;
Beauty unchaste is beauty in disgrace. *Id.*

Oft with the *enchantress* of his soul he talks,
Sometimes in crowds distressed. *Thomson.*

This life, sae far's I understand,
Is a' *enchanted* fairy land,
Where pleasure is the magic wand,
That, wielded right,
Makes hours like minutes, hand in hand,
Dance by fu' light. *Burns.*

Perhaps loose Luxury's *enchanting* smile
Shall lure my steps to some romantic dale,
Where Mirth's light freaks the' unheeded hours beguile,
And airs of rapture warble in the gale. *Beattie.*

ENCHASE, *v. a.* Fr. *enchasser* ; the same originally with encase ; Gr. εν and καψα, a chest. Originally to enclose one body within another ; to insert in ornamented cases, and to emboss or engrave ornaments ; and hence, to ornament, adorn generally.

What seest thou there ? King Henry's diadem,
*Enchased* with all the honours of the world !
*Shakspeare.*

When was old Sherewood's head more quaintly curled,
Or looked the earth more green upon the world,
Or nature's cradle more *enchased* and purled ?
*Ben Jonson.*

And yet no doubts the poor man's draught controll ;
He dreads no poison in his homely bowl :
Then fear the deadly drug, when gems divine
*Enchase* the cup, and sparkle in the wine. *Dryden.*

Like polished iv'ry, beauteous to behold ;
Or Parian marble, when *enchased* in gold. *Id.*

Words, which, in their natural situation, shine like jewels, *enchased* in gold, look, when transposed into notes, as if set in lead. *Felton.*

ENCHEA'SON, *n.s.* Old law. Fr. *encheason.* Cause ; occasion.

And for this *encheason* the prince was, in the life of his father, sente thither, to the ende that the authoritie of his presence should refraine euill disposed parsons fro the baldness of their former outerages. *Sir T. More.*

Certes, said he, well mote I should to tell
The fond *encheason* that me hither led.
*Faerie Queene.*

ENCHIRI'DION, *n. s.* Lat. *enchiridium* ; from Gr. εν and χειρ, the hand. A small book (which one may carry in the hand) ; a manual.

Erasmus I take to have written the most and best that ever man wrote ; yet almost all were first sent abroad in very few sheets, or small *enchiridions.* *Boyle.*

ENCIR'CLE, *v. a.* } Old French, *encercler*,
ENCIRCLET, *n. s.* } from en and CIRCLE, which see. To surround ; environ. Encirclet, is a ring ; a circle.

In whose *encirclets* if ye gaze,
Your eyes may tread a lover's maze. *Sidney.*

That stranger guest the Paphian realm obeys,
A realm defended with *encircling* seas. *Pope.*

*Encircled* in her clasping arms,
How have the raptured moments flown !
How have I wished for fortune's charms,
For her dear sake, and her's alone ! *Burns.*

He spoke,—to Heaven his arms repentant spread,
And kneeling bowed his gem-*encircled* head.
*Darwin.*

Lo ! where the stripling, wrapt in wonder, roves
Beneath the precipice o'erhung with pine
And sees, on high, amidst the' *encircling* groves,
From cliff to cliff the foaming torrents shine :
While waters, woods, and winds, in concert join,
And Echo swells the chorus to the skies. *Beattie.*

ENCLASP, *v. a.* From en and clasp. To clasp ; embrace.

When shall my soul, in silent peace,
Resign life's joyless day ;
My weary heart its throbbings cease,
Cold mouldering in the clay ?
No fear more, no tear more,
To stain my lifeless face ;
*Enclasped*, and grasped
Within thy cold embrace ! *Burns.*

ENCLI'TES, *n. s.* } Gr. εγκλιτικα of εγ-
ENCLIT'IC, *adj.* } κλινω, I incline. Parti-
ENCLIT'ICS, *n. s.* } cles which throw back the accent upon the foregoing syllable.

It is observed too often, that men of wit do so much employ their thoughts upon fine speculations, that things useful to mankind are wholly neglected, and they are busy in making emendations upon some *enclites* in a Greek author, while obvious things, that every man may have use for, are wholly overlooked. *Addison.*

There are three *enclitic* particles in the Latin, viz. que, ne, and ve ; but in the Greek many, as τε, μεν, μοι, με, σε, σοι, σῃ, πως, πη, τε, γε, φημι, ειμι, ποτε, and others. *Dr. A. Rees.*

ENCLOSE, *v. a.* } Fr. *enclorre* ; Lat. *in-*
ENCLO'SER, *n. s.* } *cludo* ; i. e. *in* and *claudo*,
ENCLO'SURE. } *clausus*, to shut up. From en and close. To environ ; surround ; encircle ; hence to part off from other things or property ; to appropriate. Enclosure is the act of enclosing or separating off ; the state of being, and the space or ground enclosed.

The fourth row a beryl, and an onyx, and a jasper they shall be set in gold in their *enclosings.* *Ex.* xxviii. 20.

And all, that else this world's *enclosure* base
Hath great or glorious in mortal eye,
Adorns the person of her Majesty. *Faerie Queene.*

*Enclosures* began to be frequent, whereby arable land was turned into pasture. *Bacon's Henry VII.*

The protector caused a proclamation to be set forth against *enclosures*, commanding, that they who had *enclosed* lands, accustomed to lie open, should lay them open again. *Hayward.*

If God had laid all common, certainly
Man would have been the' *encloser*; but since now
God hath impaled us, on the contrary,
Man breaks the fence. *Herbert*

Let no man appropriate what God hath made common; that is against justice and charity, and by miraculous accidents God hath declared his displeasure against such *enclosure*. *Taylor.*

The membranes are for the comprehension or *enclosure* of all these together. *Wilkins.*

As much land as a man tills, and can use the product of, so much he by his labour *encloses* from the common. *Locke.*

For the young, during its *enclosure* in the womb, there are formed membranes inveloping it, called secundines. *Ray.*

This expresses particularly the *enclosure* of the waters within the earth. *Burnet's Theory.*

'Tis not the common, but the *enclosure* must make him rich. *South.*

They are to live all in a body, and generally within the same *enclosure*; to marry among themselves, and to eat no meats that are not prepared their own way. *Addison's Spectator.*

For *enclosing* of land, the usual way is with a bank set with quick. *Mortimer's Husbandry.*

The peer now spreads the glittering forfex wide,
T' *enclose* the lock; now joins it, to divide. *Pope.*

Then snug *enclosures* in some sheltered spot,
Where frequent hedges intercept the eye,
Delight us, happy to renounce awhile,
Not senseless of its charms, what still we love,
That such short absence may endear it more.
*Cowper.*

ENCO'MIUM, *n. s.*
ENCO'MIAST,
ENCO'MIASTIC, *adj.*
ENCOMIAS'TICAL.
Gr. εγκωμιον, from the verb εγκωμιαζω to praise. Panegyric; praise. An encomiast, he who speaks or proclaims praise. Encomiastic, encomiastical; laudatory, panegyrical.

The Jesuits are the great *encomiasts* of the Chinese. *Locke.*

How eagerly do some men propagate every little *encomium* their parasites make of them! *Government of the Tongue.*

A vile *encomium* doubly ridicules;
There's nothing blackens like the ink of fools. *Pope.*

ENCOM'PASS, *v. a.*
ENCOM'PASSMENT, *n. s.*
From en and COMPASS, which see. To surround; enclose; move round; encircle.

Look how my ring *encompasseth* thy finger;
Ev'n so thy breast encloseth my poor heart.
*Shakspeare.*

Finding
By this *encompassment* and drift of question,
That they do know my son, come you more near.
*Id.*

Two strong ligaments *encompass* the whole head of the femur. *Wiseman's Surgery.*

Poetic fields *encompass* me around,
And still I seem to tread on classic ground.
*Addison.*

Onward sweeps the rolling host!
Heroes of the' immortal boast!
Mighty Chiefs! Eternal shadows!
First flowers of the bloody meadows
Which *encompass* Rome, the mother
Of a people without brother! *Byron.*

Lest, thus *encompassed* with funereal gloom,
Like me, ye bend o'er some untimely tomb,
Pour your wild ravings in Night's frighted ear,
And half pronounce heaven's sacred doom severe.
*Beattie.*

ENCO'RE, *adv.* French. Again; once more. 'A word used at public shows when a singer, or fiddler, or buffoon, is desired by the audience to do the same thing again.'—Dr. Johnson. We have retained this singular definition of our great lexicographer, written, as it would seem, when he was disappointed of some compliment of this kind. This adverb, however, has become the parent of a verb; see the instance.

To the same notes thy sons shall hum or snore,
And all thy yawning daughters cry *encore*.
*Dunciad.*

Dolly, in her master's shop,
*Encores* them as she twirls her mop.
*Whitehead.*

ENCOUNT'ER, *v. a.*, *v. n.* & *n. s.*
ENCOUNT'ERER, *n. s.*
Fr. *encontre*; Spanish and Port. *encontrar*, from Latin, *in*, and *contra*, against; opposite. To engage or run against; to meet front to front, or in opposition; applied to casual as well as premeditated conflicts.

The lion will not kick with his feet, but he will strike such a stroke with his tail, that he will break the back of his *encounterer* with it. *More.*

Putting themselves in order of battle, they *encountered* their enemies. *Knolles's History of the Turks.*

I am most fortunate thus to *encounter* you:
You have ended my business, and I will merrily
Accompany you home. *Shakspeare. Coriolanus.*

*Encounter* so,
As doth the fury of two desperate men,
Which, in the very meeting, fall and die. *Id.*
Our wars
Will turn into a peaceful comic sport,
When ladies crave to be *encountered* with. *Id.*

See they *encounter* thee with their hearts' thanks;
Both sides are even. *Id. Macbeth.*

Oh these *encounterers*! so gilt of tongue,
They give a coasting welcome ere it comes;
And wide unclasp the tables of their thoughts
To every ticklish leader. *Id. Troilus and Cressida.*

Two black clouds
With heaven's artillery fraught, come rattling on
Over the Caspian; then stand front to front,
Hov'ring a space, 'till winds the signal blow
To join their dark *encounter* in mid air. *Milton.*

Jurors are not bound to believe two witnesses, if the probability of the fact does reasonably *encounter* them. *Hale.*

As many as are the difficulties which virtue has to *encounter* in this world, her force is yet superior. *Shaftesbury.*

Which way soever we turn, we are *encountered* with clear evidences and sensible demonstrations of a Deity. *Tillotson.*

Thou stronger may'st endure the flood of light,
And, while in shades I chear my fainting sight,
*Encounter* the descending excellence. *Dryden.*

Pallas the' *encounter* seeks; but ere he throws
To Tuscan Tiber thus addressed his vows:
O sacred stream, direct my flying dart,
And give to pass the proud Halesus' heart. *Id.*

The doctrines of the reformation have kept the field against all *encounterers*. *Atterbury.*

Those who have the most dread of death, must be content to *encounter* with it, whether they will or no. *Wake.*

Propitious Pallas, to secure her care,
Around him spread a veil of thickened air,
To shun the' *encounter* of the vulgar crowd. *Pope.*

An equality is not sufficient for the unity of character; 'tis further necessary, that the same spirit appear in all sorts of *encounters*. *Id.*

O! shun, ye noble train
The rude *encounter*, and believe your lives
Your country's due alone. *Somervile.*

ENCOUR'AGE, *v. a.*
ERCOUR'AGEMENT, *n, s.*
ENCOUR'AGER.
Fr. *encourager*; Ital. *incorragiare*, a compound of en and courage. To inspirit; embolden; animate with courage or strength.

They *encourage* themselves in an evil matter. *Ps.* lxiv. 5.

Kinds of musick *encourage* men and make them warlike, or make them soft and effeminate. *Bacon.*

I would neither *encourage* the rebels, nor discourage the protestants' loyalty. *King Charles.*

Where art is *encouraged* it will soon rise high, and go far; and not suffer a channel of the sea to stay it from the presence of a more bountiful patronage. *Bp. Hall.*

For when he dies, farewel all honour, bounty,
All generous *encouragement* of arts. *Otway's Orphan.*
Live then, thou great *encourager* of arts,
Live ever in our thankful hearts. *Dryden.*

But, on the contrary, his own confession, bringing always with it perfect impunity, should be, besides, *encouraged* by some marks of approbation. *Locke.*

As the pope is a master of polite learning, and a great *encourager* of arts; so at Rome these arts immediately thrive, under the *encouragement* of the prince. *Addison.*

Such strength of heart
Thy conduct and example gives; nor small
*Encouragement* Godolphin, wise and just. *Philips.*

The reproach of immorality will lie heaviest against an established religion, because those who have no religion will profess themselves of that which has the *encouragement* of the law. *Rogers.*

Genuine Christianity is distinguished above all other religions by the mildness of its spirit; the enemy of every practice which hardens the heart; the *encourager* of every virtue which renders the character humane. *Robertson. Sermons.*

C. SURF. To be sure, I once thought the lady seemed to have taken a fancy to me; but, upon my soul, I never gave her the least *encouragement*:—besides, you know my attachment to Maria. *Sheridan.*

Planters of trees ought to *encourage* themselves, by considering all future time as present; indeed, such consideration would be a useful principle to all men in their conduct of life, as it respects both this world and the next. *Bp. Watson.*

The day before, fast sleeping on the water,
They found a turtle of the hawk's-bill kind,
And by good fortune, gliding softly, caught her,
Which yielded a day's life, and to their mind
Proved even still a more nutritious matter,
Because it left *encouragement* behind: *Byron.*

ENCRATITÆ, or ENCRATITES, in church history, heretics who appeared towards the close of the second century; they were called Encratites, or Continents, because they gloried in abstaining from marriage and the use of wine and animal food.

ENCROACH', *v. a., v. n. & n. s.*
ENCROACH'ER, *n. s.*
ENCROACH'MENT.
Fr. *accrocher*; Spanish, *corchetar*; from French, *croc*, and Spanish, *corchete*, a hook. To draw away or seize another's possessions: hence, as a neuter verb, to creep on gradually; to pass bounds; generally applied to the gradual invasion of another's right; taking *on* before the subject.

Those Irish captains of counties have *encroached* upon the queen's freeholders and tenants. *Spenser.*

The superstition that riseth voluntarily, and by degrees mingleth itself with the rites, even of every divine service, done to the only true God, must be considered of as a creeping and *encroaching* evil. *Hooker.*

This hour is mine; if for the next I care, I grow too wide,
And do *encroach upon* death's side. *Herbert.*

They fabled how the serpent, whom they called
Ophion, with Eurynome, the wide
*Encroaching* Eve perhaps, had first the rule
Of high Olympus. *Milton's Paradise Lost.*

But this usurper his *encroachment* proud
Stays not on man: to God his tower intends
Siege and defiance. *Id.*

Tisiphone, let loose from under gronnd,
Before her drives diseases and affright;
And every moment rises to the sight,
Aspiring to the skies, *encroaching on* the light. *Dryden.*

As a man had a right to all he could employ his labour upon, so he had no temptation to labour for more than he could make use of: this left no room for controversy about the title, nor for *encroachment* on the right of others. *Locke.*

The ancient Romans made many *encroachments* on the sea, and laid the foundations of their palaces within the very borders of it. *Addison on Italy.*

The bold *encroaches* on the deep
Gain by degrees huge tracts of land,
Till Neptune with one general sweep,
Turns all to barren strand. *Swift.*

Intrigue and refinement were feeble fences against the *encroachments* of military power. *Robertson. History of Scotland.*

As Envy pines at good possessed,
So Jealousy looks forth distressed
On good that seems approaching;
And, if success his steps attend,
Discerns a rival in a friend,
And hates him for *encroaching*. *Cowper.*

Such dire *encroachments* to prevent in time,
Demands the critic's voice—the poet's rhyme,
Can our light scenes add strength to holy laws? *Sheridan.*

His empire also was without a bound—
'Tis true, a little troubled here and there,
By rebel pachas, and *encroaching* giaours,
But then they never came to 'the Seven Towers.' *Byron.*

ENCUM'BER, *v. a.*
ENCUM'BERMENT, *n. s.*
ENCUM'BRANCE, *n. s.*
Fr. *encombrer*; It. *ingombrare*; from en and CUMBER, which see. To impede; clog; accumulate difficulties; hence to embarrass; burden: encumbrance is an impediment, load, excrescence or useless addition.

Much was the man *encombred* with his hold,
In feare to lose his weapon in his paw,
Ne wist yett how his talaunts to unfold. *Spenser. Faerie Queene.*

The best advizement was of bad, to let her
Sleepe out her fill without *encomberment*,
For sleepe, they sayd, would make her battill better.
*Id.*

We have, by this many years' experience, found that exceeding great good, not *encumbered* with any notable inconvenience. *Hooker.*

Philosophers agreed in despising riches, at best considering them as unnecessary *encumbrances* of life. *Temple.*

*Encumbered* with his vest, without defence. *Dryden.*

Dead limbs are an *encumbrance* to the body, instead of being of use to it. *Addison's Freeholder.*

The god awaked,
And thrice in vain he shook his wing,
*Encumbered* in the silken string. *Prior.*

In respect of the *encumbrances* of a living, consider whether it be sufficient for his family, and to maintain hospitality. *Ayliffe.*

Strip from the branching Alps their piny load,
The huge *encumbrance* of horrifick woods. *Thomson.*

The rose had been washed, just washed in a shower,
Which Mary to Anna conveyed,
The plentiful moisture *encumbered* the flower,
And weighed down its beautiful head. *Cowper.*

Here wealth had done its utmost to *encumber*
With furniture an exquisite apartment,
Which puzzled nature much to know what art meant.
*Byron.*

ENCY'CLICAL, *adj.* Ἐγκυκλικός. Circular; sent round through a large region.

This council was not received in patriarchal sees, which is evident from Photius's *encyclical* epistle to the patriarch of Alexandria. *Stillingfleet*

ENCYCLOPÆ'DIA, *n. s.* } Fr. *encyclopedie*; Gr. ἐγκυκλοπαιδεια, from εν, κυκλος, a circle, and παιδεια, science.
ENCYCLOPÆ'DY,
ENCYCLOPÆ'DIST.
The circle of the sciences: a system of knowledge or learning. An encyclopædist is a writer in, or conductor of, an encyclopædia.

In this *encyclopædia* and round of knowledge, like the great wheels of heaven, we must observe two circles, that while we are daily carried about, and whirled on by the swing and rapt of the one, we may maintain a natural and proper course in the sober wheel of the other. *Browne's Vulgar Errours.*

Every science borrows from all the rest, and we cannot attain any single one without the *encyclopædy*. *Glanville.*

This art may justly claim a place in the *encyclopædia*, especially such as serves for a model of education for an able politician. *Arbuthnot.*

It became the only resource of the reader,—to have recourse to Chambers's Dictionary;—or to the still more stupendous performance of the French *encyclopedists*. *Dr. Hutton.*

ENCYCLOPÆDIA, a term nearly synonymous with Cyclopædia, but preferred to it as more expressive, in denominating the present work. The late learned printer, Mr. Bowyer, justly observes, that the preposition en makes the meaning of the word more precise: for cyclopædia may denote 'the instruction of a circle,' as Cyropædia is 'the instruction of Cyrus,' whereas in encyclopædia the preposition determines the word to be from the dative of cyclus, 'instruction in a circle.' And Vossius, in his book De Vitiis Sermonis, has observed, 'that cyclopædia is used by some authors, but encyclopædia by the best.'

We have pledged ourselves to give some account of the principal works of this kind which have appeared in our language. If we advert to an earlier work or two, in other languages, it will not, we apprehend, be unacceptable to our readers.

The first work, then, to which this designation was expressly given, appears to be that of Alfarabius, an Arabian writer of the school of Bagdad, in the tenth century. It is described by Casiri (Bibliotheca Arabico-Hispana Escurialensis) in his account of the Arabian authors of this period, as a work 'ubi Scientiarum Artiumque liberalium Synopsis occurrit, unà cum accurata et perspicua earum notitiâ, definitione, divisione, methodo.' A complete list of the encyclopædias of the fifteenth and sixteenth centuries is to be found in the Bibliotheca Realis Philosophica of Lipenius, tom. i. pp. 436-7. These works rather aimed at a systematic digest of science in a series of systems, more or less comprehensive, than at embracing the whole circle of knowledge and miscellaneous literature. The most important among the early works of this kind was the Encyclopædia of J. H. Alstedius, professor of philosophy at Weissembourg, and which first appeared in 1620. It is mentioned with approbation by Leibnitz nearly a century after its appearance. The second edition, in two large volumes, folio (1630), is divided into thirty-five books. Books i. to iv. are introductory, and contain sketches of the studies and pursuits requisite to the understanding of the rest. Books v. to x. are on Philology. Books xi. to xx. on Speculative; and books xxi. to xxiv. on Practical Philosophy; xxv. xxvi. and xxvii. embrace the subjects, Theology, Jurisprudence, and Medicine; xxviii. xxix. xxx. the Mechanical Arts; and xxxi. xxxii. xxxiii. xxxiv. xxxv. History, Chronology, and Miscellanies. For an early work of this kind there is certainly great merit and comprehensiveness in this arrangement. But none of the encyclopædias had hitherto attempted an alphabetical digest of science.

This was first given to the world by Dr. Harris, under the title of a Lexicon Technicum, or Universal Dictionary of the Arts and Sciences, explaining not only the Terms of Art, but the Arts themselves, Lond. 1710; and which became the foundation, in fact, of all the succeeding works of this nature. Still it was restricted, principally, to the physical and mathematical sciences.

The Cyclopædia of Chambers, which appeared in 1728, was the earliest attempt to arrange the whole compass of human knowledge in an alphabetical form. His plan was complicated, but indicative of great mental powers in the author, and considerable research. He did not attempt to exhibit every science as a perfect whole, or in one treatise: but first laying down for his guidance a detailed scheme of all the various branches of knowledge (which he prefixes to his work), he gave each branch or ramification of science the explanation it seemed to him to require, and depended upon an extensive system of references, from one to the other, to establish their unity. In his preface,

which has been much admired, he thus concludes:—

'The ultimate view of a work of this kind should be the forming of a *sound mind*, i. e. acquiring a system of perceptions and motions agreeing to the system of things, or in the relations thereto intended by its author. The end of learning and study is not the filling of our heads with other men's ideas; that is an enrichment which may prove for the worse: richness is only a matter of secondary consideration; soundness is the first. There are many manures which the husbandman dares not use by reason they would corrupt the land, at the same time they enriched it, and lay the foundation of a disease which would in the end impoverish, and make it spend itself in unprofitable weeds.

'But it must be owned, men's heads are not so easily filled; the memory is not so tenacious as we may imagine; ideas are transient things, and seldom stay long enough with us to do either much good or harm: ten to one but what we read to-day is most of it forgot again to-morrow. And what chiefly makes new ideas of any significancy is their extending and enlarging the mind, and making it more capacious and susceptible. But neither is this enlargement the last aim; but is chiefly of use, as it contributes to the increasing our sensibility, to the making our faculties more subtle and adequate, and giving us a more exquisite perception of things that occur; and thus enabling us to judge clearly, pronounce boldly, conclude readily, distinguish accurately, and to apprehend the manner and reasons of our decisions. To which end several things may conduce that are not so much direct matters of knowledge as collateral to it; for instance, much of the school-philosophy, which, by exercising and exciting the mind, has a kind of instrumental tendency to sharpen its faculties, and needs only be read, not retained, to produce its effects.

'But even this does not amount to the full and adequate end of knowledge: this is only improving the organ; and there must be some farther end in such improvement. No man sharpens his weapon on the sole consideration of having it sharp, but to be the fitter for *use*. Briefly then, our faculties being only so many inlets whereby, and according to the measure whereof, we receive intimations of the Creator's will, and the effects of his power and action, all the improvements made in them have a tendency to subject us more entirely to His influence and direction; and thus make us conspire, and move more in concert with the rest of His works, to accomplish the great end of all things, in which our happiness and perfection consists; the perfection of a single nature arising in proportion as it contributes to that of the universe.'

Chambers's Cyclopædia consisted of two folio volumes, of which five editions were published in eighteen years. A supplement, consisting also of two volumes, folio, edited, and chiefly compiled by Dr. Hill, was published in 1754. The late Dr. Abraham Rees it is well known became the final editor of this work, and extended it, in the great undertaking of this kind to which he devoted almost twenty years of his life,—'measured,' as he tells us, 'not by fragments of time, but by whole days of twelve or fourteen hours,' to the unparallelled length of thirty-nine 4to. volumes,—unparalleled, of course, we mean, in an English work of this kind. As we have commenced with a criticism on the comparative propriety of the two leading terms of our title and his, it appears but just to extract Dr. Rees' defence of the one he adopted.

'The word cyclopædia is not of classical authority, though frequent enough among modern writers, to have got into several of our dictionaries. Some have censured us for having called the present work by this name; not considering that names and titles of books, engines, instruments, &c., are in a great measure arbitrary; and that authors make no scruple even of coining new words on such occasions, when there are no old ones to their mind. Thus it is Dr. Hooke calls his fine book of microscopical observations, Micrographia; Wolfius his book on the air, Aerometria; Drake, his book of anatomy, Anthropologia, &c.; all of them words of modern, if not of their own fabric; and on no better authority stand the names of half our later inventions, as microscope, telescope, barometer, thermometer, micrometer, &c. But it is suggested, the word cyclopædia is ambiguous, and may denote the science of a circle, as well as the circle of sciences; we answer, that as custom, the only sovereign rule of language, has determined the word to the latter sense, it is no more chargeable with ambiguity than a thousand other words of received use; no more, for instance, than micrometer, which might either denote a little measure, or a measure of little things.' *Rees' Cyclopædia, Article* CYCLOPÆDIA.

Various Universal Dictionaries of the Arts and Sciences appeared in the middle of the last century; as that of Barrow, in 2 vols. fol. 1751 and 1754, containing a bad translation of D'Alembert's Preliminary Discourse to the French Encyclopedie; Owen's New and Complete Dictionary of Arts and Sciences, 4 vols. large 8vo. 1754; the Complete Dictionary of Arts and Sciences, edited by a Dr. T. Williams, Rev. Henry Croker, &c.; and a Universal History of Arts and Sciences, or a Comprehensive Illustration of all Sciences and of all Arts, by Dr. De Coetlogon, 2 vols. fol. 1745: this latter work, it appears furnishing the first hint of the plan of the Encyclopædia Britannica. In the mean time a translation of Chambers's Cyclopædia in France suggested to the booksellers of that country the idea of the celebrated Encyclopedie of D'Alembert and Diderot.

The Encyclopædia Britannica was from the first distinguished by its method of giving all the principal sciences in distinct and considerable treatises; and, while its execution was at this period inferior, the superiority, as it has been thought, of its plan, obtained for it increasing popularity throughout all its editions. The first consisted of only 3 vols. 4to. and was completed in 1771; the second extending to 10 vols. 4to. appeared between 1778 and 1783, and included two subjects not hitherto embraced in any modern work of the kind (at the sug-

gestion, it is said, of the duke of Buccleugh), biography and history. The third edition, in 18 vols., received the important aid and large contributions to its physical science, by Professor Robison, and was edited by Mr. Colin, Macfarquhar, and the present bishop Gleig. A fourth, fifth, and sixth edition of this work have since appeared with minor improvements, and extending it to 20 vols. 4to. But its noble supplement, in 6 vols. 4to., is certainly its 'better half.'

Having thus redeemed our pledge of furnishing a sketch of the history of our principal Encyclopædias, we may, perhaps, without any illiberality advert to the singular inconsistencies and contradictions with regard to the facts and experiments of science, which seem to constitute the great objection to any very extended work of this kind. Were we to attempt to point these out in the works of our predecessors, it would be without the slightest disrespect for their labors: they are assignable, for the far greater part, to that very progress of science to which such works contribute largely. But, during the publication of one of them, the whole science of chemistry, for instance, became revolutionised: and the old system was entitled, at the end of the work, to no more consideration in a schedule of science, than were the evanescent republics and kingdoms of Napoleon's erection, to a place on the map of Europe. While the very excellence and incomparably superior execution of the supplemental wing to the other extended work of this description, throws the whole of the elder part of the edifice into shade.

ENCY'STED, *adj.* Κύστις, a bag. Enclosed in a vesicle or bag.

*Encysted* tumours borrow their names from a cyst or bag in which they are contained. *Sharp's Surgery.*

END, *v. a., v. n.* & *n. s.*
END'ER, *n. s.*
END'ING,
END'LESS, *adj.*
END'LESSLY, *adv.*
END'LESSNESS,
END'LONG, *adv.*
END'MOST, *adj.*
END'WISE, *adv.*

Sax. enð; Belg. & Teut. *ende*; Goth. *ende*; Swed. *ænda*; Hindoo *anta*; Ang.-Sax. endian is to make an end. To terminate; conclude; finish; destroy: as a neuter verb, to conclude; to arrive at the utmost point of time or space; to cease; to die: as a substantive, it means the point where a course of action or pursuit terminates, or to which it is directed; the extreme point of time, space, or length: hence, cessation; limit; ultimate state or doom; death. End-day is used by our oldest writers for the last day, and the day of death: thus also our authorised version of the Bible uses the word end. See the instance quoted. An-end means on an end: in Norfolk we have heard an early stirring housewife described as 'up-an-end betimes,' or early on her feet, i. e. busy, and not a-bed; and thus we may understand Shakspeare; 'slave, still an-end,' still here, about me. Endlong, is lengthways; in a straight direction. Endmost, at the farthest, or remotest end: endwise, erectly; on an end.

The seruaunt dwellith not in the hous withouten *eende*, but the sone dwellith withouten *eende*.
*Wiclif. Jon.* 8.

Bi paience renne we to the bateil purposid to us, biholdynge in to the maker of feith and the parfayt *endere* Iesu. *Id. Ebrewis* 11.

And God said unto Noah, the *end* of all flesh is come before me. *Bible, Gen.* vi. 13.

Jacob had made an *end* of commanding his sons. *Genesis.*

They have *ended* all my harvest. *Ruth.*

Mark the perfect man, and behold the upright, for the *end* of that man is peace. *Psalms.*

The *end* of the commandment is charity. 1 *Tim.*

———— at his *ende-day* he was buried there. *R. Gloucester.*

But after labours long, and sad delay,
Brings them to joyous rest, and *endless* bliss. *Spenser.*

Wisdom may have framed one and the same thing to serve commodiously for divers *ends*, and of those *ends* any one may be sufficient cause for continuance, though the rest have ceased. *Hooker.*

None of the heathens, how curious soever in searching out all kinds of outward ceremonies, could ever once endeavour to resemble herein the church's care for the *endless* good of her children. *Id.*

He would in one battle *end* the quarrel with them, either win or lose the empire. *Knolles.*

O, that a man might know
The *end* of this day's business ere it come!
But it sufficeth that the day will *end*. *Shakspeare.*

My guilt be on my head, and ther's an *end*! *Id.*

All the priests and friars in my realm,
Shall in procession sing her *endless* praise. *Id.*

Stayest thou to vex me here?
Slave, that, still *an end*, turns me to shame! *Id.*

Thus I clothe my naked villainy
With old odd *ends*, stolen forth of Holy Writ,
And seem a saint. *Id. Richard III.*

The lord of Stafford dear to-day had bought
Thy likeness; for instead of thee, King Harry,
This sword hath *ended* him. *Id. Henry IV.*

Except thou desire to hasten thine *end*, take this for a general rule, that thou never add any artificial heat to thy body by wine or spice, until thou find that time hath decayed thy natural heat. *Raleigh.*

In dealing with cunning persons, we must ever consider their *ends* to interpret their speeches; and it is good to say little to them, and that which they least look for. *Bacon.*

Her only *end* is never-ending bliss;
Which is, the eternal face of God to see,
Who last of *ends*, and first of causes is;
And to do this, she must eternal be. *Davies.*

If the world's age and death be argued well
By the sun's fall, which now tow'rds earth doth bend,
Then we might fear, that virtue, since she fell
So low as woman, should be near her *end*. *Donne.*

The tropick circles have,
Yea, and those small ones, which the poles engrave,
All the same roundness, evenness and all
The *endlessness* of the Equinoctial. *Id.*

Only let our merchants take heed, lest they go so far, that they leave God behind them;—lest they *end* their prosperous adventures, in the shipwreck of a good conscience. *Bp. Hall.*

Yet happy were my death, mine *ending* blest,
If this I could obtain, that breast to breast,
Thy bosom might receive my yielded spright. *Fairfax.*

There was a purpose to reduce the monarchy to a republick, which was far from the *end* and purpose of that nation. *Clarendon.*

Hear and mark
To what *end* I have brought thee hither. *Milton.*

The angel *ended*, and in Adam's ear,
So charming left his voice. *Milton.*

All our glory extinct, and happy state,
Here swallowed up in *endless* misery! *Id.*

Yet vainly most their age in study spend;
No *end* of writing books, and to no *end*. *Denham.*

As it is pleasant to the eye to have an *endless* prospect, so it is some pleasure to a finite understanding to view unlimited excellencies. *Tillotson.*

Then ease your weary Trojans will attend,
And the long labours of your voyage *end*. *Dryden.*

Heaven, as its instrument, my courage sends;
Heaven ne'er sent those who fight for private *ends*. *Id.*

Then spurring at full speed, ran *endlong* on,
Where Theseus sat on his imperial throne. *Id.*

The supreme power cannot take from any part of his property without his own consent: for the preservation of property being the *end* of government, and that for which men enter into society, it necessarily supposes and requires, that the people should have property, without which they must be supposed to lose that, by entering into society, which was the *end* for which they entered into it. *Locke.*

There would be an *end* of all civil government, if the assignment of civil power were by such institution. *Id.*

His sovereignty, built upon either of these titles, could not have descended to his heir, but must have *ended* with him. *Id.*

My God, my father, and my friend,
Do not forsake me in my *end*. *Roscommon.*

Others are apt to attribute them to some false *end* or intention. *Addison's Spectator.*

I mark the various fury of the winds:
These neither seasons guide, nor order binds:
They now dilate and now contract their force;
Various their speed, but *endless* is their course. *Prior.*

Though God's promise has made a sure entail of grace to all those who humbly seek, yet it no where engages that it shall importunately and *endlessly* renew its assaults on those who have often repulsed it. *Decay of Piety.*

For when success a lover's toil attends,
Few ask if fraud or force attained his *ends*. *Pope.*

Each pleasing Blount shall *endless* smiles bestow,
And soft Belinda's blush for ever glow. *Id.*

The causes and designs of an action are the beginning: the effects of these causes, and the difficulties met with in the execution of these designs are the middle; and the unravelling and resolution of these difficulties, are the *end*. *Broome of Epic Poetry.*

Speakers, whose chief business is to amuse or delight, do not confine themselves to any natural order, but, in a cryptical or hidden method, adapt every thing to their *ends*. *Watts.*

It is required that they should first study and understand the lessons, before they are put upon reading them properly: to which *end* each boy should have an English dictionary to help him over difficulties. *Franklin.*

But now being lifted into high society,
And having picked up several odds and *ends*
Of free thoughts in his travels for variety,
He deemed, being in a lone isle, amongst friends. *Byron.*

ENDAM'AGE, *v. a.* } Fr. *endomm.ger*:
ENDAM'AGEMENT, *n. s.* } from en and damage. To mischief; injure; prejudice

Nor ought he cared whom he *endamaged*
By tortuous wrong, or whom bereaved of right. *Spenser.*

It cometh sometime to pass, that a thing unnecessary in itself doth notwithstanding appear convenient to be still held, even without use, lest by reason of that coherence which it hath with somewhat most necessary, the removal of the one should *endamage* the other. *Hooker.*

Where your good word cannot advantage him,
Your slander never can *endamage* him. *Shakspeare.*

These flags of France that are advanced here,
Have hither marched to the *endamagement*. *Id.*

The trial hath *endamaged* thee no way;
Rather more honour left, and more esteem. *Milton.*

The being rightfully possessed of great power and riches, exceedingly beyond the greatest part of the sons of Adam, is so far from being an excuse, much less a reason, for rapine and oppression, which the *endamaging* another without authority is, that it is a great aggravation of it: for the exceeding the bounds of authority is no more a right in a great, than in a petty officer. *Locke.*

When an erroneous opinion is published, the publick is *endamaged*, and therefore it becomes punishable by the magistrate. *South.*

A great alteration doth seldom any wise *endamage* or disorder the globe. *Woodward. Nat. Hist.*

ENDAN'GER, *v. a.* } From en and danger.
ENDA'NGERMENT, *n. s.* } To put to hazard or peril: a state of hazard.

He—bade his servant Talus to invent
Which way he enter might without *endangerment*. *Spenser.*

He that turneth the humours back, and maketh the wound bleed inwards, *endangereth* malign ulcers. *Bacon.*

He finds it best for his people to exercise their faith that the serpents may bite, and their bitings may envenom, and that this venom may *endanger* the Israelites. *Bp. Hall. Contemplations.*

Every one desires his own preservation and happiness, and therefore hath a natural dread of every thing that can destroy his being, or *endanger* his happiness. *Tillotson.*

My kingdom claims your birth; my late defence,
Of our *endangered* fleet, may claim your confidence. *Dryden.*

Volatile salts never exist in an animal body; the heat required to make them volatile, *endangers* the animal. *Arbuthnot.*

The interest *endangered* is our title to heaven. *Rogers.*

ENDEAR', *v. a.* } From en and DEAR,
ENDEAR'MENT, *n. s.* } which see. To make dear or beloved; also to make dear in the sense of costly, high in price: endearment occurs chiefly in the former sense.

All those instances of charity which usually *endear* each other, sweetness of conversation, frequent admonition, all significations of love, must be expressed towards children. *Taylor.*

And in the mixture of all these appears
Variety, which all the rest *endears*. *Denham.*

Is not the separate property of a thing the great cause of its *endearment* amongst all mankind? *South.*

The only thing that can *endear* religion to your practice, will be to raise your affections above this world. *Wake.*

Her first *endearments*, twining round the soul. *Thomson.*

Such are the vicissitudes of the world, through all its parts, that day and night, labour and rest, hurry and retirement, *endear* each other. *Johnson.*

Those bodies, which, when full of life and beauty, lay in their arms, and were their joy and comfort, when dead and putrid, become but the more loathsome from remembrance of former *endearments.* *Burke.*

And these were not of the vain kind which cloys,
For theirs were buoyant spirits, never bound
By the mere senses, and that which destroys
Most love; possession, unto them appeared
A thing which each *endearment* more *endeared.*
*Byron.*

ENDEAV'OUR, *v. a., v. n.* & *n. s.* } Old. Fr. ENDEAV'OURER, } *indevoir,* from *devoir* or *debuoir,* duty; from Lat. *debeo, debitus,* to owe. To attempt; strive; labor to a particular purpose or end, taking *after* before the object: as a substantive, endeavour signifies effort, attempt, whether to attain or avoid.

Heaven doth divide
The state of man in divers functions,
Setting *endeavour* in continual motion.
*Shakspeare.*

How many *endeavour* that, not without danger of curses and uproar, which was voluntarily tendered unto Moses. *Bp. Hall. Contemplations.*

They take very unprofitable pains who *endeavour* to persuade men that they are obliged wholly to despise this world and all that is in it, even whilst they themselves live here. *Clarendon.*

To prayer, repentance, and obedience due,
Though but *endeavoured* with sincere intent,
Mine ear shall not be slow, mine ear not shut.
*Milton.*

Such an assurance as will quicken men's *endeavours* for the obtaining of a lesser good, ought to animate men more powerfully in the pursuit of that which is infinitely greater. *Tillotson.*

The bold and sufficient pursue their game with more passion, *endeavour,* and application, and therefore often succeed. *Temple.*

He appears an humble *endeavourer,* and speaks honestly to no purpose. *Rymer's Tragedies.*

I take imitation of an author to be an *endeavour* of a later poet to write like one who has written before him on the same subject. *Dryden.*

This is the hinge on which turns the liberty of intellectual beings, in their constant *endeavours* after, and steady prosecution of, true felicity. *Locke.*

For the reason of this wonder, he attempts it by mechanism, and *endeavours* to make it out by atomical aporrheas, which, passing from the cruentate cloth or weapon to the wound, and being incorporated with the particles of the salve, carry them in their embraces to the affected part. *Glanville.*

She could not make the least *endeavour* towards the producing of any thing that hath vital and organical parts. *Ray.*

About three hundred persons were condemned to the galleys, and treated most cruelly in them, upon no other pretence, but because they would not change their religion, and had *endeavoured* to make their escape out of France. *Burnet.*

I could wish that more of our country clergy would *endeavour after* a handsome elocution. *Addison.*

Of old, those met rewards who could excel;
And those were praised, who but *endeavoured* well.
*Pope.*

To *endeavour* to work upon the vulgar with fine sense, is like attempting to hew blocks with a razor. *Id.*

In order to a full acquaintance with ourselves, we must *endeavour* to know not only what we are, but what we shall be. *Mason.*

To be idle and to be poor have always been reproaches, and therefore every man *endeavours* with his utmost care to hide his poverty from others, and his idleness from himself. *Johnson.*

ENDEAVOUR RIVER, a river on the north-east coast of New Holland, with a bar at its mouth, and not having depth of water for vessels to sail more than a mile above the bar. At low water there is not above nine or ten feet water on the bar, and not more than seventeen or eighteen at high tide. The soil in the neighbourhood is not considered productive, but turtles are met with here in abundance.

ENDEAVOUR STRAIT, a narrow sea or channel between New Guinea and New Holland, about ten leagues in length and five broad, except at the north-east entrance, where it is contracted by Prince of Wales's Islands. It is about thirty miles long by fifteen wide, but contracts to not more than a mile in width at the east entrance. It was navigated by Torres as early as 1606.

ENDE'MIAL, *adj.* } Fr. *endemique;* Gr. ENDEM'IC, } ενδημιος, from εν and ENDEM'ICAL. } δημος, the people. Peculiar to a country or common among a people.

We may bring a consumption under the notion of a pandemick, or *endemick,* or rather a vernacular disease, to England. *Harvey.*

Solenander, from the frequency of the plants springing up in any region, could gather what *endemial* diseases the inhabitants were subject to. *Ray.*

What demonstrates the plague to be *endemial* to Egypt, is its invasion and going off at certain seasons. *Arbuthnot.*

ENDE'NIZE, *v. a.* From denizen. To make free; to enfranchise.

The English tongue hath been beautified and enriched out of other tongues, by enfranchising and *endenizing* strange words. *Camden.*

ENDIAN, a town in the province of Kuzistan, Persia, occupying both banks of the river Tab, which is here 240 feet broad. It is surrounded by walls which are nowhere above three feet thick; and is about two miles in circuit. Its trade is with Bassora and Bebahan. Population 4000 or 5000.

ENDINGEN a town of Baden, situated near the Rhone, seven miles north-west of Friburgh; having about 2700 inhabitants.

E'NDIVE, *n. s.* Fr. *endive;* Lat. *intybum.* A plant.

*Endive,* or succory, is of several sorts; as the white, the green, and the curled. *Mortimer.*

ENDORSE', *v. a.* } Fr. *endosser,* from Lat. ENDORSE'MENT, *n. s.* } *in* and *dorsum,* the back. ENDOSS', *v. a.* } To place on the back, by writing or otherwise. See the extract from Milton. Chiefly applied in modern times commercially, or to writing on the back of a negotiable instrument or bill of exchange.

——— A shield, in which he did *endoss*
His dear Redeemer's badge. *Spenser.*

A French gentleman speaking with an English of the law salique, the English said that was meant of the women themselves, not of males claiming by women. The French gentleman said, Where do you

and that gloss? The English answered, Look on the backside of the record of the law salique, and there you shall find it *endorsed*. *Bacon's Apophthegm.*

The' *endorsement* of supreme delight,
Writ by a friend, and with his blood.
*Herbert.*

Chariots, or elephants *endorsed* with towers
Of archers. *Milton's Paradise Regained.*

Upon credential letters was *endorsed* this superscription, To the king who hath the sun for his helmet. *Howel.*

All the letters I can find of yours I have fastened in a folio cover, and the rest in bundles *endorsed*. *Swift to Pope.*

ENDOW', *v. a.* } Fr. *douar;* Span. and
ENDUE' *v. a.* } Port. *dotar;* Lat. *indotare,*
ENDOW'MENT, *n. s.* } to give a portion to a daughter, &c., from *dos, dotis,* a portion. Skinner says that endue is a corrupt method of writing endow. To enrich with a portion or with excellence of any kind. An endowment is a property, revenue, or gifts bestowed or appropriated.

Leah said, God hath *endued* me with a good dowry. *Genesis.*

He shall surely *endow* her to be his wife. *Exodus.*

*Endue* them with thy holy spirit. *Common Prayer.*

Wisdom was Adam's instructor in Paradise: wisdom *endued* the fathers, who lived before the law, with the knowledge of holy things. *Hooker.*

These banished men that I have kept withal,
Are men *endued* with worthy qualities. *Shakspeare.*

I do not think
So fair an outward, and such stuff within,
*Endows* a man but him. *Id. Cymbeline.*

Who fights
With passions, and o'ercomes them, is *endued*
With the best virtue, passive fortitude.
*Massinger.*

I at first with two fair gifts
Created him *endowed*; with happiness
And immortality; that fondly lost,
This other served but to eternize woe.
*Milton.*

With what ease,
*Endued* with royal virtues as thou art,
Might'st thou expel this monster from his throne?
*Id.*

Whatsoever other knowledge a man may be *endowed* withal, he is but an ignorant person who doth not know God, the author of his being. *Tillotson.*

Every Christian is *endued* with a power, whereby he is enabled to resist and conquer temptations. *Id.*

A chapel will I build, with large *endowment*. *Dryden.*

An alms-house I intend to *endow* very handsomely for a dozen superannuated husbandmen. *Addison.*

Among those who are the most richly *endowed* by nature, and accomplished by their own industry, how few are there whose virtues are not obscured? *Id.*

God did never command us to believe, nor his ministers to preach, any doctrine contrary to the reason he hath pleased to *endow* us with. *Swift.*

Our souls therefore must be of a more excellent nature than theirs; and from the power of thought with which they are *endowed*. *Mason.*

Stephen Potts, a young rustic, just broke from school, and of rustic education, with *endowments* rather above the common order. *Franklin.*

Where will you find a race like theirs, *endowed*
With all that man e'er wished, or Heaven bestowed?
*Cowper.*

*Endued* with reason only to descry
His crimes and follies with an aching eye;
With passions, just that he may prove, with pain,
The force he spends against their fury vain. *Id.*

ENDRACHT'S LAND, or Concord, a large but low and sterile tract of the west coast of New Holland, in which is a spacious bay, which the French have called after the celebrated English navigator Dampier: he had previously given it the appellation of Shark's Bay.

ENDRIE, a town in the district of Eastern Caucasus, Asiatic Russia, situated on the river Akatsch, about twenty miles from the Caspian Sea. It consists of nearly 3000 houses, and is the common property of several Tartar princes, who acknowledge the authority of the Russians. Here are several mosques, an Armenian church, and two Jewish synagogues. The Jews are very enterprising in commerce; and a great trade is carried on in slaves and plunder, as all persons and their property kidnapped by the neighbouring tribes are sold or redeemed here. Endrie is acknowledged a free town by all the nations of Caucasus. It was formerly called Baal or Balek, but having been defended against the Arabs, by a governor called Endrie, became known by his name. It was burnt by the Russians in 1722.

ENDURE', *v. n.* & *v. a.* } Fr. *endurer,* from
ENDU'RANCE, *n. s.* } Lat. *durare;* Heb.
ENDU'RER. } דור, to inure to hardship. To bear or brook evil; to last; remain: as an active verb, undergo; sustain; bear patiently; support: endurance is, continuance in grief; patience; or continuance generally.

For how can I *endure* to see the evil that shall come unto my people? Or how can I *endure* to see the destruction of my kindred? *Esther* viii. 6.

Doth the crown *endure* to every generation? *Proverbs.*

Labour not for the meat which perisheth, but for that meat which *endureth* unto everlasting life. *John.*

And therewithal the king no longer *enduring* to sitte vp, laide him down on his right side, his face towarde them: and none was there present that coulde refrain from weeping. *Sir T. More.*

Some of them are of very great antiquity and continuance, others more late and of less *endurance*. *Spenser's Ireland.*

They are very valiant and hardy; for the most part great *endurers* of cold, labor, hunger, and all hardiness. *Spenser.*

Taking into the city all such things as they thought needful for the *enduring* of the siege, they destroyed all the rest. *Knolles's History.*

By thine own tongue thou art condemned, and must
*Endure* our law. *Shakspeare. Cymbeline.*

I should have ta'en some pains to bring together
Yourself and your accusers, and have heard you,
Without *endurance* further. *Id. Henry VIII.*

The hardness of bodies is caused chiefly by the jejuneness of the spirits, and their imparity with the tangible parts, which make them not only hard, but fragile, and less *enduring* of pressure. *Bacon.*

Our great English lords could not *endure* that any kings should reign in Ireland but themselves; nay, they could hardly *endure* that the crown of England should have any power over them. *Davies*

When a heart is hardened with any passion, it will *endure* much, ere it will yield to relent.
*Bp. Hall. Contemplations.*

So dear I love him, that with him all deaths
I could *endure*; without him, live no life. *Milton.*

Great things of small
One can create; and in what place soe'er
Thrive under evil, and work ease out of pain,
Through labour and *endurance*. *Id.*

The deer *endureth* the womb but eight months, and is complete at six years. *Browne's Vulgar Errours.*

I wish to die, yet dare not death *endure*.
*Dryden.*

The gout haunts usually the easy and the rich, the nice and the lazy, who grow to *endure* much, because they can *endure* little. *Temple.*

Their fortitude was most admirable in their presence and *endurance* of all evils, of pain, and of death.
*Id.*

By being able to repeat measures of time, or ideas of stated length of duration in our minds, we can imagine duration, where nothing does really *endure* or exist. *Locke.*

I would fain know whether that man takes a rational course to preserve himself, who refuses the *endurance* of these higher troubles, to secure himself from a condition infinitely more miserable? *South.*

But I who ne'er was blessed by Fortune's hand,
Nor brightened ploughshares in paternal land;
Long in the noisy town have been immured,
Respired its smoke, and all its cares endured. *Gay.*

The love of praise, howe'er concealed by art,
Reigns more or less, and glows in every heart;
The proud to gain it toils, and toils *endure*,
The modest shun it, but to make it sure. *Young.*

When disappointment snaps the clue of hope,
And through disastrous night they darkling grope,
With deaf *endurance* sluggishly they bear,
And just conclude that 'fools are fortune's care.'
*Burns.*

The *enduring* record bears the artist's name,
Demands his honors, and asserts his fame.
*Sheridan.*

Thou chief star!
Centre of many stars! which makest our earth
*Endurable*, and temperest the hues
And hearts of all who walk within thy rays!
*Byron.*

ENDYMION, in fabulous history, a shepherd son of Æthlius and Calyce. It is said that he required of Jupiter to grant to him to be always young, and to sleep as much as he would; whence came the proverb of Endymionis somnum dormire, to express a long sleep. Diana saw him naked as he slept on Mount Latmos; and was so struck with his beauty, that she came down from heaven every night to enjoy his company. Endymion married Chromia daughter of Itonus: by whom he had three sons, Pæon, Epeus, and Æolus, and a daughter called Eurydice. The fable of Endymion's amours with Diana, or the moon, arose from his knowledge of astronomy; for as he passed the night on some high mountain, to observe the heavenly bodies, it came to be reported that he was courted by the moon. Some suppose that there were two of that name; the son of a king of Elis, and the shepherd or astronomer of Caria. The people of Heraclea maintained that Endymion died on Mount Latmos, and the Eleans pretended to show his tomb at Olympia in Peloponnesus.

E'NECATE, *v. a.* Lat. *eneco.* To kill; to destroy.

Some plagues partake of such a pernicious degree of malignity, that, in the manner of a most presentaneous poison, they *enecate* in two or three hours, suddenly corrupting or extinguishing the vital spirits.
*Harvey on the Plague.*

ENEMA; Gr. ενιημι, to inject; a clyster. A well known form of conveying both nourishment and medicine to the system, by injection through the anus, under certain morbid circumstances, such as occur in lock-jaw, diseased œsophagus, &c. By these means the body can be supported for a few weeks, while an attempt is made at effecting a cure. It is composed, in such cases, of animal broths, gruels made of farinaceous seeds, mucilages, &c. As a form of medicine, clysters are no less useful; and, according to the intention with which they are prescribed, they are either of an emollient, anodyne, or purgative nature.

EN'EMY, *n. s.* Fr. *ennemi;* Span. *enemigo,* Ital. *inimico;* Lat. *inimicus;* i. e. *in* privative, and *amicus*, a friend. A foe, public or private; one that is averse from, or dislikes: applied in a particular sense theologically, i. e. to Satan, the great enemy of God and man.

Netheless bryngе ye hidur tho myn *enemys* that wolden not that I regned on hem; and sle ye before me. *Wiclif. Luk* 19.

And at the laste deeth the *enemy* schal be distried, for he hath maad suget alle thingis undir hise feet.
*Id.* 1 *Cor.* 15.

I say unto you, love your *enemies*. *Matt.*
Defend us from the danger of the *enemy*.
*Common Prayer.*

Kent in disguise,
Followed his *enemy* king, and did him service
Improper for a slave. *Shakspeare. King Lear.*

All these statutes speak of English rebels and Irish *enemies*, as if the Irish had never been in condition of subjects, but always out of the protection of the law.
*Davies on Ireland.*

They were thine *enemies* that raised thee to the cross; how can they be other than thy friends, that are *enemies* to thy most cruel and indign crucifiction.
*Bp. Hall.*

'Tis now no time to dally,
The *enemy* begin to rally;
Let us that are unhurt and whole
Fall on, and happy man be's dole.
*Butler. Hudibras.*

Pride destroys all symmetry and grace, and affectation is a more terrible *enemy* to fine faces than the small-pox. *Hughes.*

A man's wisdom is his best friend; folly his worst *enemy*. *Sir W. Temple.*

By asserting the scripture to be the canon of our faith, I have unavoidably created to myself *enemies* in the papists directly, because they have kept the scripture from us what they could.
*Dryden. Pref. to Religio Laici.*

It stands here stigmatized by the apostle, as a temper of mind rendering men so detestably bad, that the great *enemy* of mankind neither can nor desires to make them worse. *South.*

The *enemy* thinks of raising threescore thousand men for the next summer. *Addison on the War.*

He that designedly uses ambiguities, ought to be looked on as an *enemy* to truth and knowledge.
*Locke.*

Bold is the critick, who dares prove
These heroes were no friends to love;
And bolder he who dares aver,
That they were *enemies* to war. *Prior.*

Now the first steps to this are seldom thought worth our care; sometimes not taken notice of; so that the *enemy* is frequently got close up to us, and even within our trenches, before we observe him. *Mason.*

The sights he was accustomed to behold,
The wild seas, and wild men with whom he cruised,
Had cost his *enemies* a long repentance,
And made him a good friend—but bad acquaintance.
*Byron. Don Juan.*

EN'ERGIZE, *v. a.*
ENERGET'IC, *adj.*
ENERGET'ICAL,
ENERGET'ICALLY, *adv.*
ENER'GIC, *adj.*
EN'ERGY, *n. s.*

Fr. *energie*; Ital. *energia*, *enargia*; Sp. and Port. *energia*; Gr. ενεργεια, of εργον, work. 'Effectual operation.'—Minsheu. 'Efficient faculty or act.'—Wilkins. To energize is to excite to forcible and effective action; energic and energetic, are powerful in effect.

They are not effective of any thing, nor leave no work behind them, but are *energies* merely; for their working upon mirrours, and places of echo, doth not alter any thing in those bodies. *Bacon.*

These miasms entering the body, are not so *energetick* as to venenate the entire mass of blood in an instant. *Harvey.*

God thinketh with operation infinitely perfect, with an omnipotent as well as an eternal *energy*. *Grew.*

Swift and ready, and familiar communication is made by speech; and, when animated by elocution, it acquires a greater life and *energy*, ravishing and captivating the hearers. *Holder.*

Whether with particles of heavenly fire
The God of nature did his soul inspire;
Or earth, but new divided from the sky,
And pliant still, retained the' ethereal *energy*.
*Dryden.*

Matter, though divided into the subtilest parts, moved swiftly, is senseless and stupid, and makes no approach to vital *energy*. *Ray.*

Who did ever, in French authors, see
The comprehensive English *energy*?
*Roscommon.*

Beg the blessed Jesus to give an *energy* to your imperfect prayers, by his most powerful intercession. *Smalridge.*

In all your lines let *energy* be found,
And learn to rise in sense, and sink in sound.
*Garth.*

How can concussion of atoms beget self-consciousness, and powers and *energies* that we feel in our minds? *Bentley.*

Many words deserve to be thrown out of our language, and not a few antiquated to be restored, on account of their *energy* and sound. *Swift*

What but God!
Inspiring God! who, boundless spirit all,
And unremitting *energy*, pervades,
Adjusts, sustains, and agitates the whole.
*Thomson.*

'Who would have supposed,' said he, 'Franklin to be capable of such a composition? What painting, what *energy*, what fire! he has surpassed the original.' *Franklin.*

They (the works of malice and injustice) are finished with a bold masterly hand; touched as they are with the spirit of those vehement passions that call forth all our *energies*. *Burke.*

Thy language at this distant moment shows
How much the country to the conqueror owes;
Expressive, *energetic*, and refined,
It sparkles with the gems he left behind. *Cowper.*

Rouse the dull ear, the hoodwinked eye unbind,
And give to *energy* the public mind. *Darwin.*

And now, expanded to the beams of truth,
New *energies* and charms unknown before
His mind discloses. *Beattie.*

Nought's more sublime than *energetic* bile,
Though horrible to see, yet grand to tell,
Like ocean warring 'gainst a rocky isle—
And the deep passions flashing through her form
Made her a beautiful embodied storm. *Byron.*

ENERGUMENS, in church history, persons supposed to be possessed by the devil, concerning whom there were many regulations among the primitive Christians. They were denied baptism and the eucharist, in some churches; but, though they were under the care of exorcists, they were allowed the public prayers of the church, and were permitted to be present. See EXORCISM.

ENERVE', *v. a.*
ENER'VATE, *v. a.* & *adj.*
ENERVA'TION, *n. s.*

Old Fr. *enerver*; Span. *enervar*; Lat. *enervo*, *enervare*. To weaken or break the force of; make powerless. Enervation is the act of weakening, or state of being weakened; effeminacy

Great empires, while they stand, do *enervate* and destroy the forces of the natives which they have subdued, resting upon their own protecting forces. *Bacon.*

We shall be able to solve and *enerve* their force. *Digby.*

Such object hath the power to soften and tame
Severest temper, smooth the ruggedest brow,
*Enerve*, and with voluptuous hope dissolve.
*Milton.*

If that sheepish softness, which often *enervates* those who are bred like fondlings at home, be carefully to be avoided, it is principally so for virtue's sake; for fear lest such a yielding temper should be too susceptible of vicious impressions, and expose the novice too easily to be corrupted. *Locke.*

On each *enervate* string they taught the note,
To pant, or tremble through an eunuch's throat.
*Pope.*

Footmen exercise themselves, whilst their *enervated* lords are softly lolling in their chariots.
*Arbuthnot and Pope.*

Fancy *enervates*, while it sooths, the heart,
And, while it dazzles, wounds the mental sight:
To joy, each heightening charm it can impart,
But wraps the hour of woe in tenfold night.
*Beattie.*

ENERVATION is the act of destroying the force, use, or office, of the nerves, either by cutting them, or weakening them with debauchery. Excess of wine, and other strong, hot, spirituous liquors, enervates, or weakens the nerves. Too great abstinence has the same effect. A moderate use of these and other stimuli strengthens them.

ENESEI, or YENESEI, a town and river of Siberia. The latter rises in the borders of Chinese Tartary, and, taking a northern course, runs into the Frozen Ocean. The town of this name is in

the government of Tobolsk, and seated on the river. It is fortified, of considerable size, and populous; having a jurisdiction over an extensive tract, which yields a tribute of furs to the government.

ENFEE'BLE, *v. a.* En, expletive, and FEEBLE, which see. To weaken; deprive of power or strength.

> My people are with sickness much *enfeebled*.
> *Shakspeare.*

> I've belied a lady,
> The princess of this country; and the air on't
> Revengingly *enfeebles* me. *Id. Cymbeline.*

> Some employ their time in affairs below the dignity of their persons; and being called by God, or the republick, to bear great burdens, do *enfeeble* their understandings by sordid and brutish business.
> *Taylor's Rule of Holy Living.*

> Much hath hell debased, and pain
> *Enfeebled* me, to what I was in heaven!
> *Milton.*

> Sure, nature formed me of her softest mould,
> *Enfeebled* all my soul with tender passions,
> And sunk me even below my own weak sex.
> *Addison.*

> Abandoned all to soft Enone's charms,
> He to oblivion doomed the listless day;
> Inglorious lulled in Love's dissolving arms
> While flutes lascivious breathed the' *enfe[illegible]ing* lay.
> *[illegible]eattie.*

ENFE'OFF, *v. a.* } Low Lat. *f[illegible]amen-*
ENFE'OFFMENT, *n. s.* } *tum.* To inv[illegible] with any dignities or possessions; a law term

> If the eldest son *enfeoff* the second, reserving homage, and that homage paid, and then the second son dies without issue, it will descend to the eldest as heir, and the seigniory is extinct. *Hale.*

ENFE'OFFMENT, *n. s.* From enfeoff. The act of enfeoffing; the instrument or deed by which one is invested with possessions.

ENFETTER, *v. a.* From fetter. To bind in fetters; to enchain. Not in use.

> His soul is so *enfettered* to her love,
> That she may make, unmake, do what she list.
> *Shakspeare.*

ENFIELD (William), LL.D., an elegant and admired miscellaneous writer, born at Sudbury in 1741. He was early destined for the ministry, and received his education at the academy of Dr. Ashworth, a protestant dissenter at Daventry. When about twenty-two years of age he was chosen minister by the congregation at Benn's Garden, Liverpool; and soon gained considerable reputation. During his residence at Liverpool he published two volumes of sermons, and a collection of hymns and family prayers, which met with a favorable reception. He removed to Warrington about 1770, having been appointed tutor and lecturer in the belles lettres at Warrington academy; a station which he filled for several years with unremitted assiduity. Among many useful books which he compiled, the Speaker, composed of pieces of recitation from the best and most approved authors, has gained him considerable celebrity. He also published—The Preacher's Directory; The English Preacher, a collection of sermons from the most celebrated authors, in 9 vols. 12mo.; Biographical Sermons on the principal characters in the Old and New Testament; and a number of single sermons on particular occasions. His attention having been engaged by the controversy relative to literary property, he also wrote a pamphlet on that subject. He likewise published a history of Liverpool. Besides the above works, he published, during his residence at Warrington, Institutes of Natural Philosophy, theoretical and experimental, in 1 vol. 4to.; and about this time the university of Edinburgh conferred on him the degree of LL. D. After the dissolution of the academy at Warrington, in 1783, Dr. Enfield continued two years in that town in the capacity of a private tutor; but in 1785 he was chosen pastor of the Octagon meeting-house at Norwich. Not long after this, he gave up the labors of private tuition and devoted himself entirely to literary pursuits, and the duties attendant on his pastoral charge. He undertook and executed the laborious task of abridging Brucker's History of Philosophy, which he published in 2 vols. 4to. in 1791; and it has been admitted that the tenets of the different sects of philosophers were never exhibited with greater perspicuity and elegance. To the Biographical Dictionary, published under the inspection of Dr. Aikin and others, our author was an extensive contributor. He died on the 3rd of November, 1797, in the fifty-seventh year of his age.

ENFIELD, a township of New Hampshire, in Grafton county, eleven miles south-east of Dartmouth College. It had 724 citizens in 1790, chiefly farmers.

ENFILA'DE, *v. a.* & *n. s.* Fr. *enfilade, enfiler;* en and filer (Lat. *filum*). To draw out in file or threads; to extend lengthways; hence to sweep along a straight line with musquetry or artillery; a military term.

> The avenues, being cut through the wood in right lines, were *enfiladed* by the Spanish cannon.
> *Expedition to Carthagena.*

> In conducting the approaches at a siege care must be taken that the trenches be not *enfiladed* from any work of the place. To *enfilade*, is to sweep the whole length of any work, or line of troops, with the shot of artillery or small arms. *James.*

ENFILADE, in the art of war, is used in speaking of trenches, or other places which may be scoured by the enemy's shot along their whole length. In conducting the approaches at a siege care must be taken that the trenches be not enfiladed from any work of the place.

ENFINE, formerly Antinoe, a city of Egypt, built by Adrian in honor of his infamous favorite Antinous. It is situated towards the middle of Upper Egypt, and still contains several stately monuments of antiquity. This city was anciently very magnificent. It was about half a league in circumference, having two principal streets forty-five feet wide, intersecting each other at right angles, and running through its whole length. The others were more narrow, but equally straight; the two largest having gates at each end, part of which still remain. According to the Nubian geographer it was called the City of the Magi, because Pharaoh is said to have caused the Magicians to come thence to his court. Near it were the ruins of Abydos, where there was an

oracle of the god Besa, one of the most ancient in Egypt, and which was still famous in the time of Constantius. The ruins of the gates are the most beautiful pieces of architecture to be met with in this place. The handsomest has three vaulted entries; the middle one being forty feet high, twenty-two wide, and twenty thick; the other two smaller. Each of the façades of this edifice is ornamented with four pilasters in bas relief, with Corinthian capitals, the acanthus leaves of which have a considerable projection. It was surrounded by eight Corinthian columns, of which only one now remains, but the pedestals of the rest are still entire. Besides these, there are heaps of rubbish in different parts of the town, apparently the remains of ancient temples or palaces. All these seem to have been bordered by a colonnade, forming a portico on each side, where the inhabitants might walk secure from the heat of the sun. One of the squares was ornamented with four large Corinthian pillars, three of which are destroyed all but the bases. The fourth is quite entire, about fifty feet high, and the shaft composed of several stones. The pedestal has a Greek inscription, much defaced, dedicating it to the emperor Alexander Severus, to whom the senate of ALEXANDRIA had already dedicated the famous column mentioned under that article. These four other columns were therefore probably raised in honor of that emperor after his victories over the Persians; for the foliage of the oak, with which the first stone of the shaft is decorated, was a sign of victory among the Romans. Towards the end of the fourth century the city was peopled by Christians; and Palladius assures us that there were at that place twelve convents of virgins, and several others inhabited by monks. In the environs there are still several Coptic monasteries possessed by monks equally miserable and ignorant. The Nubian geographer informs us, that the city was surrounded by a well cultivated country, abounding in fruits and harvests; but these have now given place to sands and barren deserts.

ENFI'RE, *v. a.* From fire. To fire; to set on fire; to kindle. Obsolete.

> So hard those heavenly beauties be *enfired,*
> As things divine least passions do impress.
> *Spenser.*

ENFORCE', *v. a., v. n. & n. s.* } En, expletive, and force. To strengthen, invigorate, instigate, provoke, urge, compel: as a verb neuter, to attempt by force; to approve; evince. The derivations follow these meanings.
ENFORC'EDLY, *adv.*
ENFORCE'MENT, *n. s.*
ENFOR'CER.

> Fear gave her wings, and rage *enforced* my flight
> Through woods and plains. *Faerie Queene.*

> The idle stroke, *enforcing* furious way,
> Missing the mark of his misaimed sight,
> Did fall to ground. *Id.*

Which laws in such case we must obey, unless there be reason shewed, which may necessarily *enforce* that the law of reason, or of God, doth enjoin the contrary. *Hooker.*

> For competence of life I will allow you,
> That lack of means *enforce* you not to evil.
> *Shakspeare.*

> Sker away as swift as stones
> *Enforced* from the old Assyrian slings. *Id.*

> In this point charge him home, that he affects
> Tyrannick power: If he evade us there,
> *Enforce* him with his envy to the people,
> And that the spoils got on the Antiates
> Were ne'er distributed. *Id. Coriolanus.*

> All revoke
> Your ignorant election; *enforce* his pride
> And his old hate to you. *Id.*

> If thou did'st put this sour cold habit on,
> To castigate thy pride, 'twere well, but thou
> Dost it *enforcedly:* thoud'st courtier be,
> Wert thou not beggar. *Id. Timon.*

> More than I have said,
> The leisure and *enforcement* of the time
> Forbids to dwell on. *Id. Richard III.*

He that contendeth against these *enforcements,* may easily master or resist them. *Raleigh's History.*

A just disdain conceived by that queen, that so wicked a rebel should prevail against her, did move and almost *enforce* her to send over that mighty army. *Davies on Ireland.*

The personal descent of God himself, and his assumption of our flesh to his divinity, was an *enforcement* beyond all the methods of wisdom that were ever made use of in the world. *Hammond.*

When a man tumbles a cylinder or roller down an hill, 'tis certain that the man is the violent *enforcer* of the first motion of it. *Id.*

He prevailed with him, by *enforcing* the ill consequence of his refusal to take the office, which would be interpreted to his dislike of the court. *Clarendon.*

> He now defies thee thrice to single fight,
> As a petty enterprise of small *enforce.* *Milton.*

The rewards and punishments of another life, which the Almighty has established as the *enforcements* of his law, are of weight enough to determine the choice. *Locke.*

To avoid all appearance of disaffection, I have taken care to *enforce* loyalty by an invincible argument. *Swift.*

The most effectual grace is freely offered, to encourage and assist our obedience: advantages which no human laws have to *enforce* the observance of them. *Mason.*

ENFO'ULDRED, *adj.* From Fr. *foudre.* Mixed with lightning. Obsolete.

> Heart cannot think what courage and what cries,
> With foul *enfouldred* smoak and flashing fire,
> The hell-bred beast threw forth unto the skies.
> *Faerie Queene.*

ENFRAN'CHISE, *v. a.* } En and FRANCHISE, which see. To set free from slavery, custody, or the disadvantages of being an alien: to invest with the privileges of freedom.
ENFRAN'CHISEMENT, *n. s.*

> His mistress
> Did hold his eyes lockt in her crystal looks.
> -Belike, that now she hath *enfranchised* them,
> Upon some other pawn for fealty. *Shakspeare.*

> Never did captive with a freer heart
> Cast off his chains of bondage, and embrace
> His golden uncontrouled *enfranchisement.* *Id.*

Men, forbearing wine, come from drinking healths to a draught at a meal; and, lastly, to discontinue altogether; but if a man have the fortitude and resolution to *enfranchise* himself at once, that is the best. *Bacon's Essays.*

> But think that death hath now *enfranchised* thee,
> Thou hast thy expansion now and liberty. *Donne*

The English colonies, and some septs of the Irishry, *enfranchised* by special charters, were admitted to the benefit of the laws. *Davies.*

Romulus was the natura. parent of all those people that were the first inhabitants of Rome, or of those that were after incorporated and *enfranchised* into that name, city, or government. *Hale.*

If they won a battle, prisoners became slaves, and continued so in their generations, unless *enfranchised* by their masters. *Temple.*

He that is by charter made denizen of England, is said to be *enfranchised*; and so is he that is made a citizen of London, or other city, or burgess of any town corporate, because he is made partaker of those liberties that appertain to the corporation. *Cowel.*

These words have been *enfranchised* amongst us. *Watts.*

Cities gradually acquired wealth, a considerable share of the public taxes was levied on them, the inhabitants grew in estimation, and, being *enfranchised* by the sovereign, a place in parliament was the consequence of their liberty, and of their importance. *Robertson. History of Scotland.*

ENFRO'ZEN, *particip.* From frozen. Congealed with cold. Not used.

Yet to augment the anguish of my smart,
Thou hast *enfrozen* her disdainful breast.
That no one drop of pity there doth rest. *Spenser.*

ENGADINA, a territory of the Grisons among the Alps; extending along the banks of the river Inn, from its source to the Tirolese. It is divided into the Upper and Lower.

ENGADINA, LOWER, has a fertile soil and produces corn and fruits abundantly. It is subdivided into three communities. Cernetz is the chief town.

ENGADINA, UPPER, is a beautiful district, but on account of its elevation produces little else but rye and barley, the cold weather setting in early and ending late. Even in summer, the air is often very piercing and the corn much hurt by hoar frost. Hence the Italian proverb, 'Engadina terra fina, se non fosse la pruina;' i. e. 'Engadina would be a fine country were there no frost.' It is subdivided into two communities. Zuts is the capital.

ENGAGE', *v.a.* & *v.n.* } Fr. *engager*; Ital.
ENGAGE'MENT', *n. s.* } *ingaggiare.* En and gage. See GAGE. To bind, or be bound, to fulfil or accomplish certain engagements. Hence to make liable to a debt; pledge or hazard life in a service; unite, attach, employ, induce, or persuade; as well as to encounter, fight: and, as a neuter verb, to conflict; embark or enlist in any affair. Engagement has a similar diversity of application.

I have *engaged* myself to a dear friend,
*Engaged* my friend to his mere enemy.
To feed my means.
*Shakspeare. Merchant of Venice.*

The commemorating the death of Christ, is the professing ourselves the disciples of the crucified Saviour; and that *engageth* us to take up his cross and follow him. *Hammond.*

This is the greatest *engagement* not to forfeit an opportunity. *Id.*

Before I *engage* myself in giving any answer to this objection of inconsumptible lights, I would see the effect certainly averred *Digby.*

Upon advertisement of the Scots army, the ear. of Holland was sent with a body to meet and *engage* with it. *Clarendon.*

To every duty he could minds *engage*,
Provoke their courage, and command their rage. *Waller.*

Our army, led by valiant Torrismond,
Is now in hot *engagement* with the Moors. *Dryden.*

His beauty these, and those his blooming age,
The rest his house and his own fame *engage*. *Id.*
For I shall sing of battles, blood, and rage,
Which princes and their people did *engage*. *Id.*

'Tis not indeed my talent to *engage*
In lofty trifles, or to swell my page
With wind and noise. *Id. Persius.*

The merchant's wife, who abounds in plenty, is not to have downright money; but the mercenary part of her mind is *engaged* with a present of plate. *Spectator.*

Good-nature *engages* every body to him. *Addison.*

So shall I court thy dearest truth,
When beauty ceases to *engage*;
So thinking on thy charming youth,
I'll love it o'er again in age. *Prior.*

This practice may be obvious to any who impartially, and without *engagement*, is at the pains to examine. *Swift.*

Play, either by our too constant or too long *engagement* in it, becomes like an employment or profession. *Rogers.*

Encouraged by despair, or obstinate
To fall like men in arms, some dare renew
Feeble *engagement*, meeting glorious fate
On the firm land. *Philips.*

We have been firm to our allies, without declining any expence to which we had *engaged* ourselves, and we have even exceeded our *engagement*. *Atterbury.*

We have, in expence, exceeded our *engagements*. *Id.*

The rebel knave, who dares his prince *engage*,
Proves the just victim of his royal rage. *Pope.*

Or a certain sweetness of disposition, and agreeableness of manner, that is naturally *engaging*? *Mason.*

Sir Humphry, shooting in the dark,
Makes answer quite beside the mark:
No doubt, my dear, I bade him come,
*Engaged* myself to be at home,
And shall expect him at the door
Precisely when the clock strikes four. *Cowper.*
Yet hence, alas! insolvencies; and hence
The' unpitied victim of ill judged expence,
From all his wearisome *engagements* freed,
Shakes hands with business, and retires indeed. *Id.*

ENGANO ISLE, an island, about thirty miles in circumference, lying off the south-west coast of the Island of Sumatra, in lat. 5° 20′ S., long. 102° 20′ E. The male inhabitants go naked, and are fairer and taller than the Malays: their hair is black, which the men cut short, and the women wear long and turned up. They also wear a piece of plantain leaf round the waist Both men and women wear a ring of cocoa-nut, or leaves, in large holes at their ears. Their canoes are formed of planks sewed together and have out-rigging and sharp ends. They will hold six or seven men. They always carry lances made of hard wood and about seven feet long not only as weapons, but for the purpose of

striking fish. Some of these are tipped with pieces of bamboo made sharp, and the concave part filled with fish-bones and shark's teeth. Some are armed with pieces of bone made sharp and notched, and others pointed with bits of iron and copper. The soil of the island is for the most part a red clay, and the productions the same as on the coast of Sumatra. No rice has been seen among the inhabitants, nor have cattle or fowls of any kind been observed here. Their houses are circular, raised on posts, floored with planks, and about eight feet in diameter. The Malays are said formerly to have believed that the inhabitants of this island were all females. An expedition was fitted out in 1645 from Batavia, for the purpose of exploring this island; and it brought away sixty or seventy of the inhabitants, male and female. The former died soon after their arrival at Batavia, refusing to eat any other food than cocoa nuts; but the women were tractable and docile. In 1771 a vessel sent by the governor and council of Bencoolen, landed here; but owing to the petty thefts of the natives, and the imprudent conduct of the crew, hostilities soon arose between them which frustrated the purpose of the expedition. Large plantations of cocoa-nut trees were discovered on the shore with several spots of ground cleared for cultivation. Canoes came off to the ship, with cocoa-nuts, sugar-canes, toddy, and a species of yam.

ENGA'OL, *v. a.* From gaol. To imprison; to confine.

> Within my mouth you have *engaoled* my tongue,
> Doubly portcuilised with my teeth and lips.
> *Shakspeare.*

ENGA'RRISON, *v. a.* From garrison. To protect by a garrison.

> Neptune with a guard doth *engarrison* her strongly.
> *Howel.*

ENGASTRIMYTHI, in Pagan theology, the Pythians, or priestesses of Apollo, who delivered oracles from within, without any action of the mouth or lips. The ancient philosophers, &c., are divided upon the subject of the engastrimythi. Hippocrates mentions it as a disease; others will have it a kind of divination; others attribute it to the possession of an evil spirit; and others to art and mechanism. M. Scottus maintains, that the engastrimythi of the ancients were poets, who, when the priests could not speak, supplied the defect by explaining in verse what Apollo dictated in the cavity of the basin on the sacred tripod.

ENGEL (J. J.), a German philosopher, whose writings possess the happy art of treating the most abstruse subjects in a clear and popular manner. His Der Philosoph für die Welt, i. e. Philosopher for the World, and his Ideen zu einer Mimik, i. e. Ideas on Dramatic Art, are striking illustrations of this remark. He died in 1799. His works were published together in 12 vols. 8vo, at Leipsic, in 1801.

ENGEN, a town of Baden, once fortified and that has sustained several sieges. In the late revolutionary wars, it was occupied first by Moreau in 1796, at the period of his celebrated retreat; then in March, 1799, by general Jourdan; and again by Moreau in May, 1800, when he defeated the Austrians in this neighbourhood. It is not a large place, and has a population of only about 1000 inhabitants. Twenty two-miles west of Constance.

ENGEN'DER, *v. a.* & *v. n.* Fr. *engendrer*; en and gender. To procreate between two sexes; to produce from, cause, or bring forth: as a neuter verb, to be caused or produced.

> When that Aprilis with his shouris sote
> The drought of March had percid to the rote,
> And bathid every veyn in such licour,
> Of which vertue *engendrid* is the flour. *Chaucer.*

> Oh nature! thou, who of the self-same mettle,
> Whereof thy proud child, arrogant man, is pufft,
> *Engender'st* the black toad and adder blue.
> *Shakspeare.*

> The presence of a king *engenders* love
> Amongst his subjects and his loyal friends. *Id.*

> Say, can you fast? Your stomachs are too young,
> And abstinence *engenders* maladies. *Id.*

> Again, if souls do other souls beget;
> 'Tis by themselves, or by the body's power:
> If by themselves, what doth their working let,
> But they might souls *engender* every hour?
> *Davies.*

This bastard love is *engendered* betwixt lust and idleness. *Sidney.*

> Thick clouds are spread, and storms *engender* there.
> *Dryden.*

> Vice engenders shame, and folly broods o'er grief.
> *Prior.*

It unfolds the mind, *engenders* thoughts, and animates virtue. *Addison.*

Many vices, *engendered* or nourished by prosperity, delivered them (the Romans) over to the vilest race of tyrants that ever afflicted or disgraced human nature. *Robertson. Sermons.*

> If ever thou hast felt another's pain,
> If ever, when he sighed, hast sighed again,
> If ever on thy eyelid stood the tear,
> That pity had *engendered*, drop one here.
> *Cowper.*

> Yes, the hours
> Are silently *engendered* of that day
> When he, who built 'gainst Attila a bulwark,
> Shall yield, and bloodlessly and basely yield
> Unto a bastard Attila. *Byron.*

ENGHEIM, ENGHIEN, or ENGHUIN, a town of the Netherlands, in Hainault; famous for a battle fought near it, commonly called the battle of Steenkirk, between the British under king William III. and the French under marshal Luxemburgh; in which the latter were victorious; and general Mackay, the victor at Killicrankie in 1689, was killed. The great Condé also obtained a victory here; which was the origin of the ducal title which it gives to a prince of the house of Bourbon Condé. Here is a noble palace, park, and gardens. Enghien lies fifteen miles south-west of Brussels. Population about 3000.

ENGHIEN (Louis Antoine Henry, duke d'), was born in the year 1772. He was the son of the duke of Bourbon, and grandson of the prince de Condé, of whom Dr. Johnson remarked in his tour to Paris that he was a grandsire at thirty-nine; the fact was, however, still more extraordinary, for (as he was born in 1736) he was a grandfather at thirty-six. This young prince emigrated with his amiable and respectable father in 1789, after the capture of the Bastile, when he was hardly seventeen years of age;

and he served in the army of Condé with the most brilliant reputation, adored by his own soldiers, and respected for his courage, his courtesy, and his conduct, even by the republicans. This army exhibited the singular spectacle of three generations of heroes, fighting with equal courage and almost equal activity in the same field. After seven campaigns the treaty of Luneville put a period to its services.—It was disbanded, and, in 1801, when his father and grandfather came to England, the duke d'Enghien retired to the château of Ettenheim, a country residence situated close to the town of that name in Suabia.

An ardent and romantic passion for the princess Charlotte de Rohan-Rochefort, to whom it is supposed he was secretly married, induced the duke to reside at Ettenheim; where his only occupations were the sports of the field, the embellishment of his little domain, and the occasional society of her who shared and sweetened his exile. So domesticated was this young prince, and so attached to his retirement, that, till the fatal night in which he was dragged from it to assassination, he never quitted it but once, when he made an excursion to visit some of the beautiful scenes of Switzerland; but home was still more beautiful to him, and after a short tour he hastened back to Ettenheim.

For the following sketch of the sequel of this seizure, we are indebted to a spirited article in the Quarterly Review.

'On the night of the 15th of March, 1804, about 12,000 French troops, under the direction of Caulaincourt and the immediate command of generals Ordener and Fririon, crossed the Rhine in two or three divisions, and surrounded the town of Ettenheim and the residence of the prince. The duke had been apprised a day or two before that some design against him was on foot in France. He could not believe it; he was living, in a friendly country, a most peaceable and inoffensive life, under the security of his own innocence, and under the protection of the laws of nature and of nations: he could not believe it; and the assassins found that no kind of precaution had been taken against them.

'When the duke heard them surrounding the house, and breaking down the outward gates, he jumped from bed, and he and a footman named Joseph immediately armed themselves with fowling-pieces. The officers and other parts of his family soon joined him. The stairs of the castle were straight and narrow, so that from the first landing-place an obstinate defence might be made against the assailants. The duke, notwithstanding the time of the night, and the suddenness of the attack, preserved the most perfect coolness, and made the ablest dispositions for resistance; his officers and servants were to load the fowling-pieces under cover, while he, alone, at the head of the stairs, successively discharged them, with an effect the more to be relied upon from his being an excellent shot.

'The house was soon surrounded; the assailants broke the lower door, and seemed to be about to ascend the stairs, where some of them would have received the reward of their temerity, when the duke's first gentleman, a baron Grinstein, threw himself upon him, caught him in his arms, and exclaiming, that all resistance was vain, dragged him into a room which opened upon the head of the stairs. The assailants seized the opportunity; they rushed forward, and the duke, still palsied by the prudent care of Grinstein, was, with all the other persons in the room, made prisoner. It has never, to this hour, been ascertained whether the baron was actuated by a criminal motive; the fact of his interference is all we can vouch for; the duke would certainly have been finally overpowered, and one cannot help wishing, on the first impression, that he had had the satisfaction of dying amidst his dying enemies with his arms in his hand; but Providence ordained for him a still nobler fate, and fraught with a nobler lesson. Had he died in that midnight scuffle, the atrocity of Buonaparte might have been doubted; the cool heroic devotion of the young and gallant victim would not have been tried and proved; the deep and lasting indignation of Europe would not have been excited; and the retributive justice of heaven, in the fate of Murat and Buonaparte, would have wanted its highest effect, its most exemplary vindication.

'When the French entered the room, their first question was, Which of you is the duke d'Enghien? no answer was made; none of the prisoners were more than half dressed, except Grinstein, who it seems had gone to bed that night without taking off his clothes. Seeing him completely dressed, while the others were nearly as they had sprung out of bed, the French fancied, or pretended to fancy, that he was the duke. If he had had the honesty and presence of mind to say, I am the duke, he would have been carried to Strasburgh:—probably no harm would have happened to him, and the prince might have been saved. Grinstein, however, though he received a hint to this effect, was silent; and the French marched the whole party out of Ettenheim. The town was by this time in a state of consternation, and the princess Charlotte de Rohan alarmed at the noise, having risen and run to a window, saw, but it is supposed without recognising him, the duke dragged past her house, with no other covering but a waistcoat and loose trowsers, and a pair of slippers.

'At a little distance from Ettenheim, they halted at a mill where was the burgomaster of the town, whether it was he or the duke's secretary (who had followed his master and begged to be allowed to share his fate) who pointed out the duke to his guards, is doubtful, but he was now known. He asked to be allowed to send his valet back for linen, clothes and money, —it was granted,—on the servant's return, he dressed himself, and they proceeded. They passed the Rhine between Cappell and Reinau, at which latter place there were carriages waiting for them. The French wanted to place Grinstein in the duke's carriage, but he refused to be so accompanied; and insisted upon having the brave and faithful servant who had endeavoured to assist him in the defence of the house. On their arrival at Strasburg, the prisoners were confined in the citadel, and it would seem that the

jailers had not yet final orders as to the disposal of the duke; probably Caulaincourt had not returned from Offenbourg, whence he had directed the operation. The prince was, however, respectfully treated that day; but in the middle of the night his bed was surrounded by gendarmes, who forced him to rise and dress himself with all haste, as he was about to go a journey. He asked for the attendance of the faithful Joseph: he was told he would not need it. He asked to take some linen: he was answered that two shirts would suffice. This sufficiently explained to him his intended fate. He distributed to his attendants, who had now assembled round him, all the money he had, except one rouleau, and a few loose pieces of gold and silver; and, after he had affectionately taken leave of them, they were excluded from the apartment; but they heard for some minutes the noise of the preparation for departure, and amongst the rest the clank of the chains with which they had the needless barbarity and insolence to confine his arms.

'He was five days and five nights on the road during the whole of which time he was confined to his carriage, and almost without food. At the ordinary rate of travelling he might have reached Paris in seventy hours; so that some precautions must have been taken that he should arrive in the evening. It was about half-past five in the evening of the 20th of March that the young prince arrived at the castle of Vincennes, when he was delivered into the hands of the governor, who, at first, as well as the other persons, was ignorant who he was. By one of those slight incidents, which sometimes add an interest to a scene already deeply important, it happened that the wife of the governor was the daughter of the duke's nurse, and she recognised her foster-brother; overwhelmed with sorrow and consternation, she had yet the presence of mind not to betray herself, and retired, unobserved, except by her husband, to give vent to the emotions of terror and grief, and to endeavour to consider how she could be of use to the unhappy prince. The name of the royal prisoner was however soon whispered, and, as he complained of hunger and fatigue, all the inhabitants of the castle, even the officers and men of the regiment in garrison there (s'empressèrent), vied with each other in showing him attention. This alarmed the persons to whom the direction of the criminal was committed; the regiment was immediately ordered under arms, and marched off to the heights of Belle Ville, where it bivouaqued for that night.

'In the meanwhile, a mock tribunal assembled in one of the rooms of the castle. We devote to the scorn and detestation of posterity these bloody and cowardly assassins. They were

General Hulin, President.
Colonel Bazancourt.
Colonel Barrois.
Colonel Guiton.
Colonel Ravier.
Colonel Rabbe.
Captain D'Autancourt, Judge Advocate.
Captain Molin, Secretary.

All,' says the sentence, 'named by the general in chief, Murat, governor of Paris.'

'The members of this court had received the notice to attend not more than an hour before the appointed time, and they did not, with the exception of the president, know for what purpose they were summoned. Nor was it necessary they should; the sentence was ready drawn before they arrived, and the grave was actually dug before the court was assembled! Worn out with fatigue, the victim was asleep on a soldier's bed on the floor of his dungeon, when he was called to attend the court. He was awakened with great difficulty, and he entreated to be allowed to sleep again; but, as soon as he was made to understand that his hour was come, he shook off his fatigue, and prepared with a dignified alacrity for the last scene of his agony. He was introduced into the room where the court was sitting. He was asked his name: he told it. He was asked whether he had not borne arms against France: he answered that he had served the king; but when they were about to propose some other questions, he said he supposed he had told enough for their purpose, and that he would answer no more. He was then led away, and Hulin produced the sentence ready drawn up, and laid it before the astonished members for their signature. The whole scene had been so sudden—their ignorance of what they came for—of whom they were to try—the name of the young victim, which fell like a thunderbolt amongst them; all contributed to disorder their minds, and the ferocious threats of Hulin, the organ of Buonaparte and Murat, the latter of whom was present in the castle to execute them, overwhelmed their consciences, and they signed the fatal paper. We do not pretend to excuse their meanness, but we know that some of them set no bounds to their self-reproaches, and to the remorse with which they recollected that terrible scene. The bloody Hulin said, with atrocious sang froid, 'if the prince had not told us his name we should have been prettily puzzled what to do, as there was no one who could identify him.' This wretch was soon after, as the price of blood, rewarded with the office of governor of Paris, vacated by Murat's promotion to an imperial principality. In this pretended trial no witnesses were produced, nor any evidence but some papers, which are stated in the sentence to have been secretly read to the court before the prisoner was introduced.

'The moment the sentence was signed, the duke was led down to death. The night was pitch dark; the executioners could not see their victim, nor their own leaders, nor one another. The duke asked for a priest, it was refused;—he then knelt down near a square stone which happened to be there, crossed his arms, bent his head, and was for a few moments absorbed in devotion. He then requested that a lock of his hair, which he had cut off and folded up, might be delivered to the princess de Rohan—no answer being made, he exclaimed, 'Is there no French soldier who will perform this last office to a dying comrade?' One of the guard cried, I will; he received the little parcel; but neither that nor the generous soldier was ever heard of more.

During all this time, two persons stood on the rampart above the ditch, leaning over the parapet; to them the duke's demands were referred, and they, from time to time, directed the operations of the people below—these two persons are supposed to have been Murat and Savary—Murat—the hour came when he must have remembered this dreadful scene with bitter sympathy! At last, a little before midnight, the duke was placed in the ditch, with his back to the wall; he asked to give the fatal word of command—he was refused. At ten paces the soldiers could not see him; a lantern was therefore brought, which he himself tied to his button-hole. At the word fire, the duke rushed forward on the muzzles of the musquets, and fell dead at the feet of his executioners. The body was immediately taken up—unstripped and even unexamined—and flung carelessly into the grave, which had been dug before the trial. A stone was thrown into the grave near the prince's head. It has been said that this was the cowardly vengeance of one of the executioners, whose cruelty was not assuaged even by the victim's blood; but the person who filled the grave declared, that he had himself thrown in the stone as a mark to know the body hereafter. A little dog of the poodle kind had accompanied the duke; in the confusion of the trial and murder he was not thought of, but on the return of light he was found howling on the grave of his master. The poor creature was with difficulty removed from the spot; a gentleman purchased him from the man who had taken him, and protected him for many years out of affection to the memory of the unhappy prince.'

Our readers will excuse us for adding, from the same source, a few words descriptive of the finding the remains of the duke.

'On the 20th March, 1816,—the twelfth anniversary of the murder—a commission, appointed by the king of France, attended at Vincennes to search for the grave. The man who had been employed to dig and fill it up was still alive, and several persons who had visited it shortly after the event, recognised the spot. After digging about four feet deep, the boot of the right leg was discovered, and then the rest of the body successively, and lastly the head, and the stone which, before the grave was opened, the laborer stated that he had thrown in. All the bones were found. Their position showed that the body had been carelessly thrown in. It was lying rather on the face, with the head downwards, the left leg and arm bent under the body, and the right leg extended and the right arm elevated. It had been stated, by the laborer, before the search began, that the body had not been rifled; and in consequence of this information, the Chevalier Jacques—(who had been aide-de-camp to the prince, and accompanied him to Strasburg, but had been then separated from him and brought to Paris alone, where he suffered a long and rigorous imprisonment)—declared what the duke had about him when they parted, and what of course ought to be found in the grave; and it is impossible to describe the deep interest, the solemn impatience in which the commissioners, who stood around the trench, awaited each successive report of the surgeons who stood in it, and who examined every thing as the earth was turned up.

'They found about the middle of the skeleton a mass of metallic matter, of the size of a watch, but so decayed, that but for some small iron keys and a seal with the arms of Condé which adhered to it, it would have been hardly recognized;—the seal was perfect. A small red morocco purse with eleven pieces of gold and five pieces of silver. Seventy pieces of gold coin, the contents of a rouleau which M. Jacques had handed to him at the moment of their separation—the fragments of the seal of red wax on the ends of the rouleau were found, which bore the impression of the seal of M. Jacques. A ring and chain of gold, which M. Jacques declared the prince always wore about his neck, and which was found around the vertebral bones of the neck. In short, no doubt remained that the remains were those of the duke d'Enghien—they were accordingly placed in a coffin, and deposited, with the usual ceremonies of religion, in the chapel of the castle of Vincennes.

'Thus concludes the history of this bloody tragedy,' says our critic, 'the excuses for the perpetration of which only show us that Buonaparte's impudence was equal to his cruelty. The whole charge against the duke was, that he was in league with England in a conspiracy against Buonaparte;—if it had been true, Buonaparte had no right to violate treaties and the laws of nations to seize him—he had no right to try him before a packed court, chosen by Murat—to condemn him without a single witness being heard against him—and to execute him in the depth of night, with no other light to guide the executioners than a lantern fastened to his button-hole. But the alleged fact is altogether false. It is well known that England had no hand in the French conspiracies against him, —it is equally well known that the duke d'Enghien was wholly unconnected with, and ignorant of them.'

ENGIA, Egina, or Eyina, an island of European Turkey, in the gulf so called, near the coast of the Morea; anciently called Oenone, Ægina, and Myrmidonia. It is about thirty miles in circumference. Many fine relicts of antiquity are still to be seen on it. See Ægina.

# ENGINEERING

EN'GINE, *n. s.* & *v. a.* ⎫ Fr. *engin*; Ital. *ingegno*, *inganno*; Span. *engano*; Port.
ENGINEER', ⎬
EN'GINERY. ⎭

*ento*; Lat. *ingenium*, a device or contrivance. machine, instrument, or tool of art; applied various particular senses, as to military torring, steam-engines, &c. Enginery has a general application, but is particularly used by Milton for artillery, and the art of managing it. An engineer is either a maker or conductor of engines. Chaucer uses the word engine as a verb, signifying to torture.

> And right anon the ministres of the town,
> Han hent the carter, and sore him pined,
> And eke the hosteler so sore *engined*,
> That they beknew hir wickedness anon,
> And were anhanged by the neck bon.
>
> *Chaucer. Cant. Tales.*

> Recken you neuer of her fauoure sure:
> Ye may in clowds as easily trace an hare,
> Or in drye lande cause fishes to endure,
> And make the burnyng fyre his heate to spare,
> And all thys worlde in compace to forfare,
> As her to make by craft or *engine* stable,
> That of her nature is euer variable.
>
> *Sir T. More.*

> For 'tis the sport to have the *engineer*
> Hoist with his own petard.
>
> *Shakspeare. Hamlet.*

The sword, the arrow, the gun, with many terrible *engines* of death, will be well employed. *Raleigh.*

Prayer must be divine and heavenly, which the devil with all his *engines* so violently opposeth. *Duppa's Rules for Devotion.*

> This is our *engine*, towers that overthrows;
> Our spear that hurts, our sword that wounds our foes.
>
> *Fairfax.*

> We saw the foe
> Approaching, gross and huge, in hollow cube
> Training his dev'lish *enginery*. *Milton.*

> Some cut the pipes, and some the *engines* play;
> And some more bold, mount ladders to the fire.
>
> *Dryden.*

> They had the' especial *engines* been, to rear
> His fortunes up into the state they were. *Daniel.*

> Him thus enraged,
> Descrying from afar some *engineer*,
> Dext'rous to guide the' unerring charge, designed,
> By one nice shot, to terminate the war. *Philips.*

An author, who points his satire at a great man, is like the *engineer* who signalized himself by this ungenerous practice. *Addison.*

Had the vast sums which have been laid out upon operas, without skill or conduct, and to no other purpose but to suspend or vitiate our understandings, been disposed this way, we should now perhaps have an *engine* so formed as to strike the minds of half the people at once in a place of worship, with a forgetfulness of present care and calamity, and a hope of endless rapture, joy, and hallelujah hereafter. *Spectator.*

> He takes the scissars, and extends
> The little *engine* on his fingers' ends. *Pope.*

Such an army, however, far from being an *engine* at the king's disposal, was often no less formidable to him than to his enemies. *Robertson. History of Scotland.*

Whenever our neighbour's house is on fire, it cannot be amiss for the *engines* to play a little on our own. Better to be despised for too anxious apprehensions, than ruined by too confident a security. *Burke.*

> Who, kindling a combustion of desire,
> With some cold moral think to quench the fire;
> Though all your *engineering* proves in vain,
> The dribbling stream ne'er puts it out again.
>
> *Cowper.*

> Self-moving *engines* by unbending springs
> May walk on earth, or flap their mimic wings.
>
> *Darwin.*

*An* ENGINEER, in the military art, is more properly said to be 'an officer who has the care and construction of all works of both defence and attack.' Many things are requisite to form a good engineer. He should be a man of quick parts, vigilant, brave, active, and ingenious; and he ought to be particularly well skilled in the theory of all those sciences which belong to his art. His knowledge of fortification ought to be such as not only to enable him to discover the defects of a place, but to find a remedy for them; as also how a place may be most advantageously attacked or effectually defended. When at a siege he has narrowly surveyed the place, he is to make the result known to the general; acquainting him what part he judges to be the weakest, and where approaches may be most successfully made. His business is also to delineate the lines of circumvallation and contravallation, taking all the advantages of the ground; to mark out the trenches, places of arms, batteries, and lodgments, and that so as none of the works be flanked or discovered from the place. Thus it is evident that the art of an engineer stands in need of many others; its object is so extensive, and its operations attended with so many various circumstances, that it is scarcely possible for a man to make himself master of it by experience alone, even though born with all the advantages of genius and disposition that could be supposed necessary for the knowledge and practice of such an art. Experience, it must be allowed, is often more beneficial than all the precepts in the world; but, with all its advantages, it has also its defects: the fruits of experience are of slow growth; and the engineer who has contented himself with pursuing only that method of instruction, will often find himself puzzled at the moment when he should act. Much, however, of what experience would teach, through errors committed, may be learned at the expense of others from theory. The fundamental principles of this art are found in arithmetic, algebra, geometry, mechanics, hydraulics, &c.; and how fluently soever we may express ourselves in speaking, or writing, we can never give so perfect an idea as by an exact drawing; often therefore, in fortification, both are wanted; for which reason the art of drawing is indispensably necessary for engineers.

'To the qualities above mentioned,' says major James, 'must be added activity and vigilance, both which are absolutely necessary in all operations of war, but especially in the attack of such places as are in expectation of succours. The

besieged must have no time allowed them for consideration; one hour lost at such a juncture often proves irreparable. It is by their activity and vigilance, that engineers often bring the besieged to capitulate, much sooner than they would have done if those engineers had not pushed on the attack with firmness and resolution. Want of vigilance and activity often proceeds from irresolution, and that from weakness of capacity.' The office of engineer requiring such great natural qualifications, so much knowledge, study, and application, it is but reasonable that he should be exempted from all other duty, and that his pay should be suitable to the merits of his station. The word may be said to be of modern date; for, in the year 1600, persons acting as engineers were called trench-masters; and in 1622 Sir William Pelham, and after him Sir Francis Vere, officiated as trench-masters in Flanders. In 1634 an engineer was called camp-master-general, and sometimes engine-master, being always subordinate to the master of the ordnance; but about 1650, captain Thomas Rudd had the title of chief engineer to the king. In 1807 the corps of royal engineers in England consisted only of one colonel in chief, one colonel in second, one chief engineer, three colonel commandants, six colonels, twelve lieutenant-colonels, &c.; nor is the present establishment of this corps much larger.

Engineering, Civil, in contradistinction to the same profession attendant on military works, is of considerable importance to society; the occupation of the civil engineer embraces pre-eminently canals and their attendants, reservoirs, locks, basins, aqueducts, tunnels, bridges, docks and buildings in water, erecting beacons and light-houses, the cutting and forming roads, making iron rail-roads, &c. &c. To make the expert engineer requires considerable talent in the individual, joined to great personal firmness, and cautious enterprise. He should be a mathematician of the first order, with a ready aptitude of extending its powers to practical purposes; experienced in local nature, with science at command competent to assist and improve her.

The cutting of canals is in point of importance the first in order of his pursuits, and is of a very early date: for we find the Cnidians, a people of Asia Minor, projecting an undertaking of this nature: they wished the isthmus, which joined their territory, to connect itself with the continent. The oracle was consulted, and it was interdicted (Herodotus, l. i. c. 174). Basins and canals were formed in Bœotia, says Strabo, supplied by the lake Copais. The great river Euphrates was connected with the Tigris by means of a canal. A branch was also formed by Trajan near Coche, to join the same river. The Greeks, as well as the Romans, formed the design of making a canal across the Isthmus of Corinth, which joins Achaia, for the purpose of obtaining a passage by the Ionian Sea. A similar plan was projected between the Euxine and Caspian Seas. The Roman generals were fully impressed with the utility of canals, of which they executed many, as the ruins now existing demonstrate They connected the Rhine with the Iosel, and also the former river with the Moselle. Savary says, the canals in Egypt amounted in number to eighty, but they were more for the purpose of irrigation than communication. The Nile was joined to the Red Sea by an artificial channel; the work was commenced by Necos, who was followed by Sesostris and Darius; but the latter relinquished the undertaking on the information reaching him, that the Red Sea being so much above the level of the land in Egypt, it would be difficult if not impossible to prevent the overflowing of the banks, and consequent inundation of the country Under Ptolemy II. the undertaking was completed. Its width was upwards of 100 cubits, reckoning twenty-two inches to each cubit; and its depth sufficient to allow of the navigation of the largest vessels. By this canal India was enriched with the commerce of Egypt, Persia, and the coast of Africa. China, in her institutions hostile to art, has nevertheless encouraged the making of canals; and, their convenience having aided in supplying a ready transit of her commodities, she has, more perhaps from cunning than a wish to develope the powers of the human mind, intersected her country with them. The canal which runs from Canton to Pekin is in length upwards of 800 miles, and was executed about 700 years since: it has no locks, tunnels, or aqueducts, and when stopped by mountains, or other impediments, a rolling bridge is resorted to, and sometimes inclined planes. These rolling bridges consist of a number of cylindrical rollers which turn easily on pivots, and are sometimes put in motion by a windmill, so that the same machinery serves a double purpose, that of working the mill, and drawing up vessels. In this manner they draw their vessels from the canals on one side of the mountain to the other. In Europe, the nurse of science and the arts, to which in a great measure must be referred the successful completion of all great works, artificial rivers have abounded. In the year 1666 Louis XIV. gave directions for constructing a plan to connect the ocean with the Mediterranean by the canal of Languedoc. This was a bold undertaking if it be considered that all the details connected with it were to be created; every thing was new; Francis Riquet was the engineer, and he lived to complete it. This canal is upwards of sixty-four leagues in length, and is furnished with 104 locks. It runs through rocks in some places of 1000 paces in extent, in others it passes valleys and bridges by means of aqueducts of vast height. It joins the river Garonne near Thoulouse and terminates in the lake Tau, which extends it to the Port of Cette. It was begun by forming a large reservoir 4000 paces in circumference and twenty-four deep, which was supplied by water issuing from the mountain Noire.

In Germany, and the Low Countries, canals form the principal means of communication between one place and another. The canal of Bruges runs to the sea at Ostend, and is extended to Ghent, Brussels, Antwerp, and many other places. it is in depth sufficient to allow of merchantmen coming to the warehouse of its owner. These canals pass into the very streets of the above-named towns; indeed in all Flanders and

Holland, in towns of any importance, the streets are intersected by the canals. In the line of the canal the street is sufficiently wide to admit of two commodious roads on its sides, which are not unfrequently planted with double rows of trees.

Canal navigation in England may almost be said to have been commenced by the late duke of Bridgewater in the year 1759; since which time, the internal commerce having increased with the development of the industry of the people, canals have been cut in all directions, and afford a ready transit to every populous part of the island.

We propose to treat this and the various branches of civil engineering mentioned in this paper in a practical manner. The engineer entrusted with the making of a canal should be regarded as having so much of the projectors' interest at stake that the fullest confidence should be placed in him. The preliminaries to an undertaking of this nature, consist in forming a minute survey of every part of the country through which the line of the canal is proposed to pass; and this should be done in the first instance by the principal engineer: all the great heights should be accurately noted and ascertained; memorandums should be taken of all objects within the districts through which it is intended to pass; rivulets and mill-streams marked so as easily to be referred to; and the breadths of the various summits or ranges of high and low land that are to be passed accurately ascertained. When a survey is so far accomplished, a rough sketch or map should be prepared, laying down to a scale every principal object within the proposed line. This map will enable the projectors to see the various obstacles to be encountered in the work. When so much is accomplished, the advisable height of the summit-level of the canal must be ascertained in order to find the number and fall required in the several locks necessary to be constructed on its line, the proposed summit-level should be traced along the hills and ranges of high land, to see how far it is practicable to reduce it to the required height by filling up the low land by the excavated earth, or by deep cutting or tunneling. When the summit-level is finally determined on, and the line of the proposed canal, all springs and rivulets which rise above or cross this line should be traced, and the quantity of water they discharge accurately gauged: this part of the work is of the very greatest importance, as it may be turned to considerable account in affording a supply of water to the line in its neighbourhood. Mr. Eytelwein, engineer to the king of Prussia, has shown many important facts connected with this part of the subject, deduced from experience and mathematical investigation; and Dr. Young has given them to the public through the medium of the Journals of the Royal Institution; or see Nicholson's Journal, vol. iii. p. 25. In setting out the canal, a good spirit level with telescopic sights is required for tracing the levels, and when traced they are marked particularly by what is termed a bench-mark, which is no more than stakes driven into the ground at usually the distance of every two or three chains, with their tops exactly projecting above the earth so much as to ascertain the top-water level. After this line shall have been thus traced, and the bench-marks fixed, it should be accurately revised, and all sudden bends in its course rectified, so as to produce an easy undulating curve; it would be desirable to get the line as straight as possible, but ranges of high-land, and property of particular descriptions, sometimes intervene which prevents it. In such cases, as in the former for instance, it is often found more desirable to bend the line than to have recourse to deep cutting or tunneling: in the latter description may be included gentlemen's parks, gardens, &c., and where canal acts protect such property, the line must of course vary so as to pass round them. The widths and depths of canals vary in reference to the boats intended to work in them; thirty feet is a good width at the summit-level; and it is sometimes varied with us to as low as eighteen feet. In Holland they make theirs from fifty to seventy feet, and sometimes more. The Bruges Canal is eighty feet wide and sixteen feet deep. The slopes to the sides of canals are of considerable importance, and this consideration has given rise to many speculations, which have added very little to the stock of information already collected. Mr. Eytelwein has recommended that the breadth at the bottom should be two-thirds of the depth, and at the surface ten-thirds; the banks will then be in general capable of retaining their form. The area of such a section is twice the square of the depth, and the hydraulic mean depth two-thirds of the actual depth. See Nicholson's Journal, vol. iii. p. 33. The practice in our canals is to so apportion the side slopes that one foot in depth will give a horizontal base of one foot and a half. The depth of the water must be in some measure deduced from the nature of the soil to be cut through, and the draught of the boats to be employed on it. The average depth of our canals is between four and eight feet, and the banks are made one foot higher than the water is intended to stand in them. The fall given to a canal, in order to produce a stream or velocity in the water, varies with the local difficulties to be overcome; and, since inland navigation is determined to a precise point or place, the navigator calculates little upon the velocity of the stream downwards, knowing if it were made great what he might save in going down it would be lost in returning. Four inches in a mile is conceived to be a good fall for a canal eighteen feet upon the summit-level, and seven feet at bottom, and four feet deep; the velocity of the stream in such a canal is, according to Professor Robinson, seventeen inches in a second at the surface, fourteen in the middle, and ten at the bottom: from such a deduction it will not be difficult to extend the calculation to canals of greater or less dimensions. This conclusion is, however, only true of a straight river flowing through an equable channel; and as our canals are seldom straight for a mile together, but vary their course as frequently as change of place presents new difficulties, it follows, that the banks of the canals will be more often in a curved direction than a straight one; and Mr. Eytelwein anticipating such a

circumstance, remarks, 'that the velocity is greater near the concave than the convex side; a circumstance probably occasioned by the centrifugal force accumulating the water on that side.'

When a canal is accurately marked out, and the bench-marks firmly fixed, if it be found difficult to keep the bench-marks in their places, holes must be dug to supply their places, and the bench-marks put up as the excavating proceeds. When the works have arrived at this state, calculations should be made of stuff wanted, or to be spared, upon the line, in order to its being removed with as little labor as possible. The top-soil and turf removed, allows of the canal line being easily worked upon.

The ground-men, excavators, or navigators, as they are called, are in some districts also called bag-masters; to these people the digging is let, at per cubic yard, according to the nature of the soil to be excavated, and the distance it is to be removed. Their tools consist of (if in a clayey or loamy soil) a grafting tool, the handle of which is rather long, with a narrow blade of iron, forming the segment of a circle, with its concave side turned inwards, firmly riveted to the handle, and very thin at the lower end; the size varies to the caprice of the workman: they are usually about ten or eleven inches long, and six or seven inches wide. In some soils, gravel for instance, the same kind of tool is called a shovel; its blade is ground away till its lower end approaches an apex, the diverging sides from which form the slant ones, and make nearly an equilateral triangle. They have also a scoop to throw water, pickaxes, and wheel-barrows. The latter differ materially from the common machine of that name: it is framed of oak, the two sides form the handles, and also diverge away and admit the wheel between their opposite ends. Into the sides, two stout feet are framed and cross-braced: the whole is fixed together by stout bearers mortised into the sides. The bottom is lined commonly with inch elm boarding, and the sides slant all round, and are about six inches deep. The wheel is usually of cast iron, very light, and its edge not more than an inch in thickness. The beauty of the barrow consists in its lightness, and should not exceed forty pounds in weight, including the wheel. The laborer wheels the soil away in his barrow by a kind of tram-road made of planks, these being easily adjusted to all required positions.

Among the first works to be excavated should be the foundations for all locks, basins, and bridges, also the culverts and drains which are to pass under the canal. The work should be commenced as early in the spring of the year as possible, in which case many parts may be accomplished in sufficient time to allow of its settling and getting firm and dry before the winter season arrives, which, if severe, may delay its progress, and destroy such as may have been too recently set about.

The soils, through which the different lines of the canal is intended to pass, should be pierced and proved to ascertain their nature, and if good water-tight stuff, its extent traced, for on this must be determined where, and in what quantity, puddling may be required for the banks; for to prevent leakage in a canal, is that in which the engineer will display his greatest sagacity. Porous soils, or soils requiring puddle-lining, consist of gravel, sand, loose or open rock, or other earths that will let water easily through; or earths in which rats or moles take up their habitation, or such as is much perforated by worms.

Some engineers have made use of strong clay for puddling, but it has been seldom found to answer the purpose, particularly to side linings; in lining the bottoms of canals it has a better chance of succeeding. It holds so much water, that exposure to the air evaporates it, and consequently it cracks, which renders it unfit for a safe and water-proof coating, which in some canals is particularly required. The best puddle is made of a light loam, and sharp siliceous particles or sand, in the proportion of two of the former to one of the latter: it is manufactured commonly contiguous to the slope which it is intended to line, but if the bottom of the canal should require lining also, it will be necessary to so dig the puddle-ditch, or gutter, as it is called, that it may be at least three feet below the bottom of the intended canal. When the ditch is ready to receive the compost of which the puddle is to be made, the loam and sand, in the proportions above stated, should be brought and thrown into the ditch, till its bottom is covered to about twelve or thirteen inches in depth; it is then to be well covered with water, and it may stand so covered a day or two, if no particular hurry be required in facilitating the work. If expedition be required, the puddle-maker may commence his work immediately. The workmen are generally provided with a good and strong pair of water-proof boots; so equipped, they stand in the puddle-ditch. They are also supplied with a wooden chopper, or beater: the chopper is usually made of oak, with a rounded handle, and at its opposite end is the chopper, which is nothing more than a shaft worked away to an arris, and flat on its upper edge; with such an instrument they keep cutting and breaking the compost, at the same time treading it with their feet, till they get the whole completely incorporated and reduced to a tough and firm mass, and almost to a semi-fluid state all through the ditch, and, when so reduced, it is left to precipitate itself, which is effected in three or four days; and if, after having stood so long, it is found to have become settled and firm, not to give way by treading on it, it is deemed in a state to receive a second coat. When this is put into the trench, and the water let into it, the workmen should endeavour, in breaking it up, to strike their beaters quite through it, till they enter a small way into the coat previously prepared; in the same way a third coat is to be added, till the trench becomes full, and sufficiently high to reach the top-water or summit-level of the canal, or even a few inches more. When the puddling is so far advanced, the banks of the canal should be firmly made up, the towing-path formed to the proposed width intended, and the puddle should be covered by sods, and left for use; after which the banks of the puddle-ditch may be cleared away, and the lining of the sides commenced. Their slope

having been previously determined on, three feet is generally left to be supplied by the puddle-lining. In cutting down the slope, all extraneous matter should be carefully taken away, such as roots of trees and plants; all vermin holes should be well stopped and secured, and indeed every thing which is thought at all likely to disturb the coating about to be added; and when ready it should be worked down quite straight by the excavator's spade, and rendered tight and sound. After so much is done, the lining may be proceeded in, which consists in spreading on a coat of the puddle, varying from seven to twelve inches in thickness, all through the canal line, which is ready to receive it; and when this coat is properly laid, and to the satisfaction of the resident overseer, it should be sprinkled with water, and remain till the following day, when a second coat should be added, and so on, till the coating has assumed the necessary and required thickness; and when done it should be neatly smoothed down, and the water may be let into the canal.

The necessity of particularly attending to the puddle-lining cannot be too much impressed upon all those who may be concerned in canal works. Leakage in a canal is attended with so many embarrassing consequences; among them, loss of water is not the least, dilapidations of the embankments, and perhaps their being wholly carried away; for when percolation takes place, and that through made or artificial ground, its solidity is of very short duration. Nevertheless, it is but too often carelessly done; and this circumstance has led to an enormously extra expense, besides disgust in the contiguous land-owners, who have found their grounds constantly inundated by the leakage.

A canal is said to be performed by level cutting when the natural state of lands through which it has to pass is tolerably level, and approaching to a good summit-level to the next locks, both above and below it; when a line is to be cut through such grounds, nature is said to favor the undertaking, and it is, perhaps, truly said, for in Flanders and Holland the canals require no other consideration than in performing them in this way, and in them few locks are required, as a good summit-level may be accomplished by embankments, which are there called dikes. These, in countries like Holland, are of great consequence, and are commonly made wide and handsome, planted with rows of trees on their sides, and sometimes even paved; they are, in fact, the high roads of communication between one part of the country and another, and afford to the public the greatest accommodation, in giving them a dry and commodious road throughout the year, which could not otherwise be easily obtained in such swampy lands, which are more than half the year overflown by the swelling of the Rhine, and the consequent increase of water in the canals.

The Dutch have the credit of having invented the compost of puddling: it is true their canals are all so lined, and indeed without it, in canals such as theirs, it would be totally impracticable to prevent their leaking. Their embankments, or dikes, are sometimes raised twelve feet, or higher, above the neighbouring land, and the top-water level reaches within two feet of the top of the dike. The difficulty of keeping in the water, in such high embankments, must be great, where nothing but earth is applied for the purpose; but the Dutch puddle appears to make a complete barrier. The writer of this article has examined the principal dikes in Holland and the Low Countries, and he invariably found they were coated with puddle, and in a similar manner to the way described above for weak or infirm embankments, except, perhaps, that they are more neatly done than with us, and they use a kind of marly clay in the compost, which is often rejected by our engineers. Indeed, canal making, in Holland, is a system interwoven with the nature of the country. It would be a complete swamp if it were not for the canals: they perform the double purpose of facilitating inland navigation, and draining the country.

Plate I. fig. 1, ENGINEERING, is the section of a canal, showing it under circumstances of level cutting. A A the line of the contiguous ground; B, B, the artificial embankments; C C the width of the cut at top, and D D at bottom. The external slopes can be so formed as to be used for the towing paths. With respect to the slopes C, D, they are determined upon the principles already stated as prevailing among our best engineers for that purpose, viz. for every foot in depth, [illegible] a horizontal base of one foot and a half; [illegible] it follows, from such received data, that a canal six feet deep will require its sides to be sloped three feet, and, if it should be eighteen feet wide at the top water level, it would be fifteen feet at the bottom: hence may be deduced very useful proportions for canals of greater dimensions, [illegible] which may be combined the practice found of utility in the smaller ones.

Canals are cut through so many variations in the ground surface, that it would be impossible to anticipate them all: it is intended here, however, to notice two other cuttings, which will, in some [illegible], allow of great extension of application. When the ground slopes down to the projected canal line it is called side-lying; and, if a canal be forming through such ground, the work is said to be doing in side-lying ground. Plate I. fig. 2, shows the section of a canal for such cutting. A A the sloping line of the ground; B, B, the embankments to be raised; C C the width of the cut at top, and D D the width at bottom. It is of some importance to so arrange the cutting, that the ground excavated from the canal be equal to make up the embankments on its sides: it is impossible that it should be so in all cases, but a great expense may be saved if a calculation be made of it previously to setting out the summit-level of the work, as then the removal of the soil may be wheeled to the parts where it is most required, which will prevent heaps collecting about the works, which generates slovenliness, and sometimes the greatest inconvenience. Deep cutting arises when the canal approaches a hill, or the side of one, which it is intended to pass by deep or open cutting, rather than by tunneling. Plate I. fig. 3, represents the section of a canal by deep cutting; A A the inclined ground to be passed; C C,

width of canal at top, and D D the width at bottom; the sets-off I, I, are generally appropriated in such cuttings for the towing-paths, and are called by the navigators berms. They are also found to be exceedingly useful as a provision to prevent the loose ground which rolls down from the upper banks B and C from falling into the canal. It is in cutting in such situations that the ability of the engineer displays itself; he has often to contend with all the difficulties of a bad stratification, in which, frequently, the percolating waters become so great as to stop the proceedings. In such cases, pumps are had recourse to; but it sometimes happens, nevertheless, that he has no place into which he can convey the superfluous water, or, if he has, he is not sure that it will not increase his difficulties, rather than remove them. To offer expedients for such circumstances is impossible; they must be met by the experience and resources of mind of him to whom the work is confided, and it will be well or ill performed, in proportion as his experience and talent predominate.

Canals of great traffic must be furnished occasionally in their course with passing places. They consist in giving an increase of breadth to the water way of the canal, so as to admit of boats resting by the way, without incommoding the navigation; every canal has them, and the only precautions are, that they be made in as convenient places as can be, to promote the convenience of the traffic; hollow and low places are generally selected as the most eligible, and near to the locks and basins if possible. By such places being formed, the public derive accommodation, as it admits of a ready transit of produce and industry to the inhabitants in its neighbourhood. Reservoirs to canals, in most cases, are indispensable, in order to the keeping up a supply of water in its line; they are artificial collections, getting their water from every source in their neighbourhood; their size must be regulated by the quantity of wa[illegible] intended to contain, and that by the line of work which it may be intended to supply. They should be placed in situations so as to contain an equable quantity throughout the year, and so contiguous to the canal, as to admit of an easy communication with it at all times. Wherever the reservoir is to be constructed, all the variations of the ground's surface should be exactly noted down; the nature of the soil proved, in order to ascertain, if bad and porous, where, and in what quantity, lining or puddling may be required for it. The water flowing through all springs, brooks, and rivulets, which it is determined to divert, to supply the reservoir, should be exactly gauged, and also the depth of the rains which usually fall. All such particulars being ascertained, the excavation may be commenced; the same process is to be followed as has been recommended for the same kind of work in canals. The sloping of the banks is made rather more oblique than is practised for canals, commonly to every foot in depth a horizontal base of two feet, and, if the excavation be in a strong clay, the horizontal base is made as much as three feet. The lining is performed in a similar manner to the way pointed out for such work in canals. Every reservoir should be furnished with a gauge, indicating exactly the quantity of water that it can supply &c.; if the gauge be a wooden post fixed in the reservoir, it might be accurately divided, so as to show, by its divisions, the water lost by evaporation, or taken for the canal; and this gauge would exhibit at once how the supply kept pace with the consumption. In the event of an excess of water flowing into the reservoir, which circumstance should always be anticipated in its construction, many plans have been suggested for disposing of it; the most usual way, however, of providing for a ready exit to such excess, is to form a weir or weirs, sometimes called tumbling bays, frequently at the corners, if the form of the reservoir be square; if round, or a compound figure, at such places as is best adapted to its ready discharge. It will appear quite obvious, that the size and number of the tumbling bays must be regulated by the estimated quantity of water they may be called upon to discharge, or the greatest inconvenience may follow; as in the event of their being too small or too few in number, in great swells of the springs arising from unusual rains, &c., the sides of the reservoirs may be overflown, to the destruction of its banks and perhaps to the effect of blowing up and carrying away the canal works in its neighbourhood. The construction of a tumbling bay consists in forming a vertical syphon in the embankment of the reservoir, composed of well-wrought masonry or brick, properly cemented, to which a horizontal communication is opened by the side of the embankment of the reservoir. The whole workmanship should be done in the most complete and perfect manner; the bottom of the syphon should enter a culvert constructed in a similar way, which culvert or drain should be arched above and below, and be built upon an easy descent, so as to promote an easy discharge of its contents. The culverts are frequently carried under the bottom of the reservoir, in which case it will be essential to keep them sufficiently low to admit of the lining being thick enough to secure its water-tight qualities. In cases in which rivulets or other streams are diverted to the supply of the reservoir, a somewhat different construction will be required than when it is fed by springs; this difference principally consists in an alteration of the approach by which the water is to enter; such water is previously collected into a branch, or, as it is termed, a feeder, which is in fact a canal of smaller dimensions than the principal one. This feeder is constructed so as to promote a current in its waters to the head of the reservoir, which it enters by a weir or gates, the sides or piers of which should be formed of masonry, built on a piled foundation, in carrying up the work, which should be of large stones well joined, and the walls battering back from the line of their base, and somewhat curved in their whole height. The tops should be coped with broad slabs of granite or freestone, dovetailed together, or well cramped. The bottom of the weir should be formed by an inverted arch of masonry, well bedded in strong clay or puddle compost. The gates should be made of strong oak, with lower

and upper sills, framed with rails and cross braces, fixed in the stone sides by bars of iron. An iron upper rail should traverse the top side of the whole. The gate or weir should be in height a few inches above the summit level of the reservoir, that the water from the feeder may flow over the bar of iron attached to the upper sill. The reservoir supplies the canal by means of a pipe of cast iron, or other metal, or stone. This pipe is furnished with a cock which works on an endless screw, and is so adjusted as to be easily turned by the overseer of the reservoir.

Mr. Longbottom obtained a patent for the construction of reservoirs (see Repertory, vol. 4. p. 145), the only novelty in which was, he depended for a supply of water to the rains falling upon the earth's surface, which he proposes to collect together into one or more reservoirs; the words of the patent run thus: 'my intention is calculated to supply canals, ponds, sluices, towns, or any other place wanting water, by making reservoirs upon high and moorish ground, or any other suitable place which are to be supplied in manner following.' He adds farther, that 'he found that in twelve months there fall upon a superficial foot of land 3·33 cubical feet of rain-water, exclusive of exhalation, so that upon a statute acre there fall to the amount of 145,054,80 or thereabouts;' again, he says, 'I can convey water falling upon 3500 acres into reservoirs:' for instance, 'I make a reservoir of 100 statute acres in the most eligible situation, from which open drains, or sluices are made in the most proper places for receiving water running from the surface of the grounds in rainy weather, which, according to calculation, will be nearly equal to 5076 cubic feet per acre, or 91,800 cubic feet per annum, brought into the reservoir, except in loss by soakage; this may be done without any prejudice to rivers or mills. The area of a reservoir of 100 statute acres is 4,356,000 superficial feet, and the average depth 9·75; the parts are not included, so that 4,356,000 the area by 9, gives 39,204,000, as contained in the reservoir of reserved water.' For conducting such water into the canal or sluice, he says, 'I make two aqueducts of stone or brick for conveying the water out of the reservoir, from the bottom when the water falls perpendicular from its surface into the space of a large circle of stone-work, with which the openings of the aqueducts communicate; in each of these I fix a paddle or clough equal to an opening of fifteen inches by twelve inches, which is raised by a screw fixed to it, and moving upright in a piece of iron fixed across at the upper part of it; upon it is a square box including a female screw, in which the other moves, which is turned round by four small hand-levers fixed to the square box, and which rests upon a small iron bar, which raises the screw and also the paddle, to the following heights, viz.: with an opening of three inches by twelve inches may be delivered 317,952 cubic feet of water in twenty-four hours; with one of six inehes by twelve inches, 630,730 feet; with one nine inches by twelve inches, 927,936 feet: with one twelve inches by twelve inches 1,222,560 feet; and one twelve inches by fifteen inches, 1,512,000 feet, or a less, or a greater quantity, in proportion to the opening and velocity. The quantity of water required to be let out of the reservoir may be regularly ascertained, by fixing at the head of the screw a pointer, and an index above it accurately divided into inches and parts; and, as the paddle is raised by the screw fixed to it, the pointer at the end sliding upon the index will show the quantity of water discharged upon every division of it as set forth; as at three inches in height, 317,952; at six inches, 630,730; at nine inches, 927,936; and so in proportion to all the several proposed elevations.' This specification concludes with directions for forming smaller reservoirs, in which many ingenious suggestions are developed. The reservoirs here treated of have been considered as formed by embankments, which, in porous soils, have been recommended to be lined with puddling; in some, however, such embankments will not answer the purpose, in such cases the whole must be walled with brick or masonry, and if of the former, the greatest care should be taken that they be well laid, and of great substance, with puddle-linings behind them; the cement should be of fresh stone lime (and if ground instead of slaked with water the better,) mixed with sharp sand, and the mortar prepared for use only as wanted. The walls should batter back in their height, with a small curvature outside, diminishing in thickness as they ascend, and finishing finally at the top to two bricks and a half. The whole should be coped with granite, with the meetings fastened by dovetails. If it be determined to form the walls in masonry, which, in some situations, may be eligible from the abundance of stone at hand, the same plan in the form of the wall should be had recourse to; and also, in previously lining the embankments, the ashlerings should be in as large pieces as may be conveniently obtained, and all venty or bad stones rejected. The joinings should be as close as possible, with very little cement between them: the whole should be coped, as is directed before, for walls of bricks. Most of our canals are supplied by reservoirs somewhere in their course, so that an engineer can scarcely anticipate a work of canal-making without feeling that he may be called upon to exert his talents to the forming of a reservoir. Reservoirs that have been lately formed to canals are—one at Ripley for the Cromford Canal; another at Milstone for the Grand Junction; also, at Ainsworth for the Nottingham; at Marsden for the Huddersfield; at Littleborough on the Leicestershire Canal. The Rudyerd Vale supplies the branch of the Caldon and Mersey, and occupies upwards of 150 acres, and is more than thirty feet high. The St. Ferriol reservoir to the canal of Languedoc occupies a space of 590 acres; the walls of which are covered with ashlerings of freestone.

Locks, or pound locks, in the consideration of which many important circumstances develope themselves in the work of a canal, are the barriers by which the water is kept to its summit-level; in the several reaches on its line they also operate as toll bars for collecting the tolls payable on navigating it: they are placed as frequently on the line of the canal as the several levels require

them, and make a kind of step in the line throughout its course. They have been the great desideratum in canal-making among the moderns, as by the making of which, waters have been pent up in the reaches between them, supplying the means of navigation through high and low lands, from one part of the kingdom to another. In setting out a lock care ought to be taken to get their falls as equal as possible, and this can only be done by the previous care taken in adjusting the summit-level of the canal. The lock comprises of itself a chamber and two pairs of gates; the former is made of length and width adequate to admit one or more boats at a time either in ascending or descending the canal; this is effected by letting the water out of the chamber; if it be ascending, by opening the lower gates: but it is not usual to keep the lower gates of a lock shut, so that a boat or boats coming up the canal can be immediately towed into the lock, which, when in this state, is said to be empty, although it contains as much water at least as is in the lower reach of the canal; when boats have thus entered the lock, the lower gates are loosened, and the paddles of the upper gates are gradually raised, which admit the water to rush into the chamber of the lock: the velocity of the stream soon closes completely the lower doors: and when they are shut, the upper gates are regularly opened till the water has completely filled the lock, which it does in a very short time, and becomes at rest between the lower gates and the upper reach of the canal. The tolls being paid to the overseer of the locks, the boats are towed out, and if no others are waiting to descend the canal, the lower gates are opened and the upper ones are again closed, when the lock empties itself and regains its former state It will be perceived, that the upper line of the canal will lose its waters in proportion to the working of the locks, hence it becomes desirable to make them as small as possible; and it is also of importance that they should be of the same size throughout the line of the canal, that the loss at each lock may be equal, in which case the supply to be anticipated may be correctly ascertained. In the approaches to all locks, both above and below them, there should be made resting places, provided with oaken piles driven down close to the embankments, which they may be made to support, with their upper ends crossed by strong whaling boards of oak, bolted with iron bolts to the heads of the piles. If the whaling boards have large iron rings fixed in them, the bargemen will have the advantage of fastening their barge to them during the time they may have to wait for passing the lock. Twenty-five-ton boats, according to Mr. Fulton, consume, in ascending a lock of eight feet rise, 163 tons of water, and in descending the same, 103 tons; now, if such a datum be correct, it would enable an engineer to make very accurate calculations of the loss in water in all his several locks upon the proposed line of the canal; that more water should be lost by ascending a lock than in descending, appears probable, although the same space requires filling in both cases; but it does not appear so obvious, how so great a difference as sixty tons can take place; but this could be settled by a reference to the draft of the boat employed, knowing that it displaces as much water as its cubical contents, if it be laden adequately: these are all investigations pressing on the consideration of the engineer. Plate I. fig. 4, is the ground plan of a lock; A, A, A, A, strong piers of masonry or brickwork bonded into the wing walls, F, F, F, F; B the chamber of the lock; C, C, the gates; D, D, the side walls of the chamber; E, E, the vertical syphons to take off the superfluous water from the head of the lock. The building of a lock requires the utmost attention in all its constructive parts; when the form is traced out, and the top soil removed, the ground should be proved to ascertain its nature. and if soft and porous the foundations should be piled all through, the tops of the piling should be regularly sawn down and planked with oak of not less than three inches in thickness; which planking will form the platform on which the walls are to stand; in forming the foundation wall, some attention must be had to the inverted arch, which composes the flooring of the chamber of the lock. See section, plate I. fig. 5. The inverted arch, K, should be formed of hewn stone of small curvature; its thickness in the centre about two-thirds of that of its spring; the joints of the voissoirs are also all traced from the centre of curvature of the arch, and also the springing line; the bottom of the arch should lie upon a good lining of puddle, and the joints of the stones should be well cemented so as to be water-tight; the abutments, or bottom of the side-walls of the chamber, should be of twice the thickness to what they are above, and should rack-back in ascending; linings of puddle will be judiciously employed in covering the earth of the embankment behind the chamber walls. Lock walls are usually parallel to each other, and the lock varying in width from fourteen to eighteen feet, and in length from seventy to ninety feet. The plan, (plate I. fig. 4) is conformable to this proportion: the side walls of the chamber batter back as they approach the coping at their tops, about six inches from their perpendicular; and if they were made to have a slight curvature in their height, they would be much stronger for it. In building the piers, as shown in the plan at A, it is necessary to observe, that they should be out of large blocks neatly worked and hollowed out to admit of the gates working in them. The wing walls should be raised in a similar way to the walls of the lock, except that no provision is required in them to receive an inverted arch, as the approach or breast of the lock requires no such protection. Apertures should be made through the side walls of the wings to admit of the superfluous water entering the culvert through the syphon, as seen in the plan at E, and in the section by the dotted lines; and if the culvert be bent in its course, this water, if it be required, may be made to enter the chamber of the lock, a circumstance of some importance when there is a scarcity of water. When the lock is so far formed, and its syphons and culverts made, the lock sills should be put down; they consist in forcing into the ground, at the two ends of the bottom of the chamber of the lock, a row of narrow piles extending from one side to the other:

they should be driven as close together as possible, and, when so driven, they will form a chain across the two ends of the lock; in this state their tops should be sawn off quite level and smooth, and a sheeting, as it is called, of good oak or cast iron should be bolted on them with iron bolts, to form the lock sill for the gates to move upon, and also to protect the approaches to the lock. In the wing walls there should be inserted in their progress some large blocks of stone, projecting somewhat from the face of the ashlering of the wall, and called bumping stones, for the boats to strike against as they enter the approaches to the lock. The lock walls and those of the wings should be coped with granite, firmly fixed and cramped. The gates C, C, are made in two parts, and form at their meeting an obtuse angle; they move in the hollow quoin stones, and by means of iron joggles fitted into sockets, which should be let into the hollow quoin stones of the piers A. Plate I. fig. 5, is the section of the lock; GG the granite coping; HH the top of the sloping side walls; II the base of the sloping wall; K the inverted arch at the bottom of the lock; L, L, the syphons of masonry or cast iron, worked up in the wing walls at the head of the lock to carry off the overflowing water; MM the culvert or drain; N a cesspool to receive any matter carried by the water through the culvert, to prevent its overflowing or stopping up; O, O, the horizontal apertures in the wing walls communicating with the syphons L, L. These apertures should be made a few inches below the top-water level, and if formed in stone composed of a large block perforated quite through, and the size of the opening regulated by the quantity of water to be discharged, but they might be formed of cast iron with the best success. It will be unnecessary to add, that all the work of a lock requires the materials and workmanship of the very best quality, and the engineer will more develope his constructive talent in adjusting its form and the mode of putting the materials of which it is to be formed together, than he can in any other of the arrangements arising out of the works connected with canal construction. Plate I. fig. 6, is a pair of lock gates: they are shown to a larger scale than the plan or section of the lock which accompanies them, in order to exhibit the mode of their framing more obviously. They should be made of good seasoned oak, free from vents or sap, and are composed of several pieces known by the following designations: P, P, the balance beams; Q, Q, Q, Q, the rails; R, R, R, R, the vertical stiles; S, S, S, S, the braces; T, T, the paddle holes; and they are finally covered by oak planking, grooved into the bottom rail and the balance beam at top, the joints of which are also rebated, or grooved and tongued. In some lock gates the boarding is fitted in diagonally, in which case the braces may be dispensed with; but greater strength can be accomplished by framing them as shown in fig. 6, and there will be also a saving of wood. The scantling of the timber in the lock gates may be varied to meet the pressure they may have to sustain, but it will be indiscreet to attempt making them too light. The rails Q, Q, Q, Q, should not be less for ordinary purposes than ten inches in depth and six inches and a half in thickness, and this would be a very good scantling for the stiles R, R, R, R; and, supposing the planking to be two inches and a half, the cross braces S, S, S, S, would be properly proportioned to be left seven inches on the face by four inches in thickness. The balance beam, which also forms the top rail of the gates may be made somewhat larger in scantling than the lower framing, and the stiles might be framed into it. If this beam was made at its smallest end eight inches square, and at its opposite end ten inches and a half, it would act as a good balance to the gates, and give them great strength. The boarding should be flush on the upper side, and well spiked to the middle rail and also the braces. The projecting edges on the inside of the gates of the rails and braces should be splayed downwards in order to the water running quickly off them, and the balance beam should be weathered on its top edge. The iron work to the gates consists merely of its hinges, the sockets of which are previously inserted in the stone quoins of the wing walls. In fixing the iron work it should be made to lap quite over the outside stiles and be bolted with iron bolts, with nuts, and screws. Sometimes the bottom of the gates is shod by plates of cast iron and these plates are also continued up the centre stiles, and it must add great additional strength to the framing. Some have recommended the giving to the external form of lock gates a small degree of curvature, supposing, no doubt, that by such curvature they would give additional strength to the gates; but the momentum of form would be more than surpassed by the loss of strength in the materials, as cutting wood purposely circular so crosses its grain as to leave it with very little strength at its joining, besides a double expense in the actual cost of the gates themselves. It has been deemed proper to notice this circumstance to prevent theoretical engineers from disappointing themselves in the application of curvatures to wooden framings in which strength is sought; for it will lose strength by such curvature in a ratio of greater proportion than it can possibly gain it, which will be easily discovered by an inspection of the state of the fibre in circular wood framing.

The paddle holes T, T, are small openings left in each gate, generally about twenty inches square, and to which a small door is fitted; they are found of the greatest utility in preventing a too sudden swell in filling the chamber of the lock, and also in removing a portion of the pressure of the water from the gates when they are required to be opened in letting a boat descend the canal. They are so adjusted to the boarding of the gates that they can be easily raised or lowered by the overseer of the locks. This is done by supplying a guard bar to the top of the gate, which is operated upon by a rack and pinion, that has the effect of lowering or raising the paddle-doors at pleasure. Amidst the considerations arising out of the detail of a lock, it will be proper to notice that in long lines, and on which there is great traffic, sometimes there arises too great a scarcity of water to supply the upper reaches, in consequence of which many expedients have been recommended, and some have been had

*recourse to, to avoid the inconvenience. On the Grand Junction Canal reservoirs have been made,* to collect the waste water of the lockage, to which a steam engine has been erected, which pumps the water, after having emptied itself into the reservoir, back again into that part of the canal from which it has been lost. And there has been also another expedient recommended to remove the same inconvenience, under the designation of side ponds. A side pond or ponds consist in forming, on the right and left of the chamber of the lock, a number of projecting cisterns, varied gradually in their elevation, beginning a small distance from the bottom, at the lower end of the lock, and stepping up to the upper end or head of the lock, provided with paddle doors. These cisterns, in capacity, are made so as to contain all the water, or nearly so, that passes the upper gates on a boat or boats, ascending or descending the lock. When the chamber of the lock is full, the highest paddle-doors are opened, and the water empties itself into the cisterns right and left, and so on till all the cisterns are full, observing to shut the doors of the cisterns as the water retires in the lock; and this is done till the chamber of the lock is so emptied as to allow of its lower gates being opened. When the boat ascends or descends the canal, it will be seen by this plan that very little waste or consumption of water by lockage can accrue, except that which must necessarily be so by allowing a sufficient quantity in the bottom of the lock to keep the boat afloat and level with the lower level of the water of the canal. Mr. Playfair, an architect who gave rise to this invention, obtained a patent for it in July 1791; the specification of which may be seen in the Repertory, vol. iii. p. 303. In the patent the application is supposed to be employed under the following circumstances, for example: 'a lock is supposed to be constructed twelve feet deep, sixty feet long, and six feet wide,' and it is calculated that the quantity of water required to fill such a lock, to enable it to pass a boat is 4320 cubic feet, and in ascertaining what water may be necessary for supplying the canal, allowing for waste by evaporation and soakage, it is found (according to the number of boats that may be expected to pass), that there will not be above 800 cubic feet for each; and hence, it is added, it will be necessary to save five-sixths of the whole; to do which ten cisterns are directed to be made, each of which must be one foot deep, and each have a surface of 360 feet superficial. The aperture or entrance to the lowest cistern must be one foot above the level of the water in the lower part of the canal, and eleven feet under the level of the high water; the second cistern two feet above the level of low water, and the third three feet, and so on. It has been deemed desirable to quote so much of Mr. Playfair's specification to illustrate the application of side ponds, and it cannot fail of producing a conviction of their great utility to canal locks, whenever there is reason to anticipate a want of water, as generally the greatest source of its loss is by the lockage. By the application of side ponds, this inconvenience may be, in a *great measure, superseded, and at no grea additional expense to the works.*

Basins.—These are formed in all towns to which the canal has a communication, in order to make a commodious place for the boats to unload their cargoes and to take in fresh ones. Their size varies according to the importance of the town, or to the trade carried on at it. Surrounding the basins, a spacious area of ground should be gotten to admit of warehouses, cranes, toll-houses, and other stowage for goods, being built with adequate space for all the vehicles employed in the trade to receive a ready transit and exit in their business about the basin. Convenient approaches should be formed to the wharfs for carts, and also roads with the shortest and readiest way of their departing when laden or unladen. The toll-house should be placed near the principal entrance to the basin, and should consist of two or more rooms for the keeper, with an office and weighing bridge. In the office should be written, in legible characters, the different tonnage and other charges to be collected, by the keeper, of the persons who trade on or about the basin of the canal. The construction of a basin consists in forming a chamber or head, sufficiently capacious to admit of boats resting in it, with room to unload and retire. The size, as before observed, must be commensurate to the number of boats expected at the basin. The embankments should be quite level with the wharfs, on contiguous ground, and about one foot higher than top-water level. The termination of the basin is generally made to form a bow or semi-circle on the plan. All the enbankments are faced by walls of masonry or brick, and the tops should be coped with large blocks of granite. In raising the facings to a basin, the same precautions should be had recours to which have been previously recommended in the construction of the chamber of a lock; for instance, if a soft and porous soil, piling must be employed in the foundations, with a covering of oaken plank, and the earth enbankment must be covered with a puddle-lining previously raising the walls of the facing. The walls should be of great thickness at the bottom, racking back on their outsides and battering over on their insides; and their slope will require to be in proportion and parallel to the canal embankment, in order to the general surface of the lines approximating together. In carrying up the facing walls, nevertheless, a few niches of curvature to produce a swell internally in their height, would add greatly to their strength in resisting pressure. A basin must also be provided with a weir, syphon, or waste gate, in order to discharge the water constantly flowing into it from the upper reaches of the canal by waste of lockage, &c. If it be determined to discharge this water by a weir or syphon (perhaps more than one may be necessary), culverts should be made to receive the water and discharge it at the most convenient places; these culverts require executing in the most substantial manner to prevent their blowing up by the weight of water they may be called on to discharge. They should have also some cess-pools in their course to receive any solid or other

matter floated into them through the weir or syphon. Some basins are released from overflowing by a waste gate; this is the case with the basin to the Oxford canal at Oxford. This basin is so near the river Isis as to admit of an easy communication with it; and, availing itself of this circumstance, the bank between them has been pierced through, and the embankment at the piercing right and left has been faced by masonry. See plate I. fig. 7. From the waste gate, VV, the walls right and left are splayed off at the embankments of the canal approaching the basin, and turned circular at their opposite ends, a rebate is left in the masonry for the gates to hang in at W W. The tops of the walls are coped with strong freestone, and the gates X are of oak, but without paddles. Returning again to the basin, it will be necessary to observe that guard-rails are found necessary to be fixed against their walls to prevent the boats from striking against them. The guard-rails consist of a series of strong oaken piles driven down into the bed or bottom of the basin, slanting to the side of it at intervals of about ten feet; and on their facing near their tops are broad planks or rails of oak strongly bolted to them with iron bolts. These generally form a continued chain, traversing the whole facing or embankment of the basin. Iron rings are fixed into the rails or piles at convenient intervals, for the purpose of allowing the bargemen to lash their boats to, while taking out their cargoes. In some cases large stones are worked in the walls for this purpose, and called bumping-stones, to which rings may be fixed for the lashing to of the boats.

It will be necessary, in this place, to notice the several contrivances had recourse to for supporting the water in a canal, against accidents to its embankments, and other unforeseen events arising out of the imperfection of the means employed for such purpose. Safety-gates are among the expedients made use of in such a dilemma; they are a contrivance for stopping the water in a long line of a canal when there is danger of the embankments giving way. Plate I., fig. 8, shows the plan of a safety gate or gates: P, P, the walls of masonry or brickwork built in each opposite bank of the canal; R, R, R, R, piers of masonry to strengthen their extreme ends; E, E, small projections worked up to stop and hinge the gate to; K sinkings in the wall to admit of the gate laying in flush with the wall; D the safety-gate. The plan is shown with two gates, one for the purpose of supporting the water in the upper, and one also for the lower reach of the canal; and these can be shut as required by the repairs to be done, whether up or down the canal. These gates move upon the same principles as lock-gates, and require a similar contrivance, excepting that they are commonly in a single gate only. The walls of the safety-gate should be built on piled foundations of adequate substance at bottom, racking back outside, and battering inside, with a slight curvature: they should also be coped at their tops. The gates should be of good sound oaken wood, and prepared in a similar manner to lock-gates. See plate I., fig. 6. Advantage is sometimes taken, for the purpose of economy, of forming the safety-gates in the pier walls about the bridges, if bridges of masonry happen in eligible places for the purpose. They are of the greatest utility on a canal, and claim particular attention in arranging the most eligible site for their erection; and their mode of building should be of the most substantial kind. They are indispensable in long levels, to protract dilapidation, where the cuttings are much embanked.

There is also a contrivance of a similar nature called stop-gates, the construction of which does not differ materially from the safety-gate, except in its being made to lie flat at the bottom of the canal, instead of being balanced above, as is the case with safety-gates. The mode of raising the stop-gate is by a chain, which is fixed to the gate under water, and, when it is required to be raised, the chain is used for that purpose. Stop-planks are also often employed on canals for stopping water; they are a very simple contrivance, and consist in previously working up walls in the two opposite banks, formed with a groove or chase, into which the stop-planks are forced, and pressed down to the bottom of the canal. These answer the purpose effectually on narrow canals. Stop-bars are another contrivance, similar in manner to stop-planks, the walls for which are grooved to receive the bar. These are used as toll-bars, at the toll-offices on the canal line, and are to be so contrived as to be opened and shut by the overseers attending at the toll-houses. They may be esteemed the turnpike gates of a canal.

Aqueducts are frequently employed on a canal, for the purpose of extending it over rivers, and between two opposite ridges of high land. For this latter purpose they were often erected by the Romans, to convey water for their baths and fountains, as the ruins of many of which, still in existence, fully demonstrate. But the Roman aqueducts were never intended for any other purpose than to convey water for the people's use; hence they were confined in their dimensions, and were a little more than long narrow walls, with a void through them as a passage for the water. The aqueduct at Chapanost, near Lyons, is raised upon arches of masonry, on the tops of which is a narrow channel for the water, arched over at top, the size of which is six feet high and three feet wide, lined in the inside with a lining of strong cement about six inches in thickness, which is quite perfect even at this time. There is another at Montpelier, which passes the river De Baunon, and crosses the valley, of a similar construction. Louis le Grand ordered an aqueduct, which is built after the same manner, and which conveys the water to Versailles. They are also numerous in every part of Italy, and wherever else the Romans extended their power; but since the discovery of Galileo, which demonstrated the important effects of the weight and pressure of the atmosphere, aqueducts in the Roman manner have become useless; as his discoveries showed that water would not only elevate itself to the syphon line, but might be raised to about thirty-four feet above that line, by the means only of the atmospheric pressure.

Plate II. fig. 1, Engineering, is the plan of a design of an aqueduct bridge to cross a navi-

gable river, supposed of 300 feet wide. A, A, the piers; B, B, the wing piers and walls; C C C the water way; the longitudinal dotted lines show the course of the aqueduct in the superstructure. Fig. 2 is the elevation: it has been deemed proper to show a bridge of this description, with some reference to architectural design, which is too often neglected, when the expense would not be increased by attending to it, as whether a stone or brick is placed in one way or another, there can be no difference in its expense by such placing, but in this placing arises all the difference between the artist and the artisan. Fig. 3 is the cross section of the bridge; C the spring of the centre arch, showing the splaying sides and its intrados: H the solid masonry above the springing line; D, D, the embankments and towing-path to the aqueduct; E E the width of the water way at top; F F the width of the water way at bottom. The rounded parapets I, I, are proposed to be raised above the towing path right and left, as a protection to the passengers moving on the sides of the aqueduct. The construction of an aqueduct bridge requires all the talents necessary to be displayed in the erecting of other bridges, with the additional skill of giving to the road way water-tight qualities. The piers of a bridge of this description should stand on piled foundations, in order to give them the greatest firmness, and the usual process of erecting pieces of masonry in water should be followed. Caissons, or water-tight boxes, should be made to raise the piers in, until they are built above the top-water level; the abutment piers should be formed behind a coffer-dam, and the whole of these parts of the substructure should be raised to a similar height previously to raising the centering on which the arch is to be built. For a particular description of the caisson, coffer-dam, and other details connected with bridge-building, see the article MASONRY.

Stone is the eligible material for building aqueducts, inasmuch as a greater firmness will result to the parts, and without a firmness and equilibration in it, the aqueduct will be subject to leakage and dilapidation. The embankments at the two opposite ends or wings should turn somewhat outwards, to allow of more easy approach, as is common in most bridges. The sides or banks of the aqueduct, crossing the bridge, should be formed of solid masonry or brick-work, and of good substance, battered over as they approach their tops, and somewhat curved, which will add to their strength and solidity. The edges of the wall should be coped, and the banks or towing-paths paved. The lining of the aqueduct should be conducted in a similar manner to puddling, excepting only it should not be common lining of that nature. Parker's cement makes an excellent lining, and is perfectly water-tight: this might be laid on the masonry to a consistence of about an inch in thickness, smoothly spread, to the face of which a coating of common puddling might be applied, which together would be a secure protection against leakage.

The multiplication of canals in every part of the country, with the experience arising out of it, has produced the application of new buildings of various kinds in aid of them: and there has been an aqueduct erected to the Shrewsbury Canal, composed almost wholly of cast-iron, and which may be considered as the first of the kind ever formed. In the Rev. Mr. Plimley's Report of the Agriculture of Shropshire, is the following account of it:—'The canal passes the valley of Tern at Long, for a distance of sixty-two yards, upon an aqueduct made of cast-iron, excepting only the nuts and screws, which are of wrought iron; and I believe this to be the first aqueduct for the purposes of a navigable canal which has ever been composed of this metal. It has completely answered the intention, although it was foretold that the different degrees of heat and cold would be such as to cause expansion and contraction,' from which it was concluded to be improper for this purpose. It is necessary only to observe, that the objections to iron were founded in fact, as all metals are more or less influenced in their form by different degrees of temperature; and it was extremely probable, in the situation of an aqueduct, which is exposed so much to the vicissitudes of heat, cold, and oxidation, that it might turn out to be improper for that purpose. Time can only be the test of the propriety of establishing aqueducts of cast iron. Nevertheless, there are several at this time erecting, but, in some of these, there is a greater combination of stone, and also of wood, than has been employed in the one at the valley of Tern. Mr. Fulton, in his treatise on canal navigation, proposes that the 'butments and piers should be raised of stone, after which it will be necessary to extend pieces of timber across the span, and each to be traced back and covered with planks, to form a stage or scaffolding; on this is fixed the iron work of the aqueduct which may be all cast in open sand, and of the following dimensions; for instance, the span 100 feet, and the versed sine of the arch one-sixth of the span; then three segments of a circle, each in three pieces, about thirty-six feet long, eight inches by four inches diameter, and to be united; then three straight bars to extend from one pier to another, to be of the above diameter, may also be cast in three pieces, and which bars are to extend along the tops of the segments to the piers, and form a line parallel to the horizon. The bars and segments to be united by perpendicular stirrups, ten or fifteen feet distant from each other. The mortise in the lower end of the stirrup, being thirteen inches long, will be sufficient to secure the segment, and leave room for a hole two inches square, through which a cross brace is to pass and fasten the segment at proper distances. The brace to have a mortise cast on each side of the stirrup, in order to allow of tightening the work by wedges. The trough plates should be at least one inch thick; the side plates six feet wide, and as long as can conveniently be cast, which may be twelve feet, and perhaps more, the flange to be made outside of these plates. The bottom plates may be six feet wide and thirteen feet long, and, in order to support the horse-path, two of these plates laid across the stage and screwed together, with a flange under them, will compose a length equal to one of the side plates. The whole may in this manner be screwed together on packings of wool and tar, and the

seams pitched. On the plates composing one side of the trough, brackets about three feet from the top must be cast and fixed, in order to support the horse-path: perpendicular rails, eight feet long, being raised from the arms of the bottom plates will support the outside of the horse-path. It is added, that, by pursuing this method of forming an aqueduct of cast iron, very few patterns will be required; two will be sufficient for the trough-plates, and but few will be required for the springs, rails, and spurs.

Mr. Jessop undertook a most stupendous work of this kind on the Ellesmere Canal, for crossing the Dee River, in which are employed nineteen ponderous pillars of stone, at fifty-two feet distance from each other, the centre one of which is 126 feet high. On the tops of these pillars are supported a number of elliptical cast-iron ribs, which, by means of uprights and horizontal bars, support an aqueduct of cast iron 329 yards long, twenty feet wide, and six feet deep, formed of massy sheets of cast iron cemented and riveted together, having, on its southern side, an iron platform for the horse or towing path. It will be necessary to observe, that every aqueduct ought to be provided with stop-gates at the most convenient parts of its length, as well as syphons or other means to drain off the water if required, for repairs or accidents. The stop-gates will be necessary to effect this purpose, and provision should be made for their erection in the first beginning of the work. They are most usually placed at the approaches or wings of the aqueduct.

Tunnels, or subterraneous passages, are now become familiar, as a means of conveying canals through ridges of high ground and mountains; they are also formed as roads through hills and under the beds of great rivers, to keep up easy communications between parts otherwise inaccessible, except by circuitous routes. Perforations for this purpose were not unknown to the ancients, for we find the Romans frequently making them in order to carry forward their aqueducts. For this purpose they were not required on a large scale, but, although small, they gave rise to the practicability which, to the ingenious, was a sufficient stimulus to create the means of performing greater undertakings; and which has now been acquired and effected through the multiplied local impediments which have presented themselves to inland navigation. The first subterraneous canal or tunnel ever made for the navigation of boats, was at Beziers, on the Languedoc Canal in France; and it is believed the first in England was at Worsley, by the late duke of Bridgewater, but this was to establish a communication to his coal mines only. However, there are now almost as many tunnels as there are canals, and the business of making them is so well understood, that they are set about with as few preliminaries as the deep cutting of a canal.

Previously to beginning a tunnel, the hill through which it is to be formed should be bored in several parts, to ascertain the nature of the soil to be excavated. This being well ascertained, the needful tools and machinery can be collected, that the work may proceed without delays. In setting out a tunnel, it is necessary to observe, that it must be quite straight from one end to the other. It tracing the line of it over the surface of the high ground, a number of small round poles are made use of, their tops painted white, to give them a more obvious direction to the sight: these are set up firmly with braces, at about 150 yards apart, and called, by the navigators, excavators, or miners' bench-marks. When the line of the tunnel is accurately traced out, another row of bench-marks should be fixed parallel and opposite to the first, at a small distance vertically from the greatest diameter of the tunnel. These bench-marks will be the places where the shafts or pits are to be sunk, for the purpose of assisting the excavators or miners, and also of allowing the soil to be raised through. In sinking the shafts, which should be at least seven feet in diameter, and as deep perpendicularly as the lowermost line of the bottom of the tunnel, a kirb should be made of wood, consisting of two circular ribs, and placed four or five feet from each other, and boarded over. With this kirb the shafts can be sunk to any proposed depth, without danger of the ground giving way; and the steining of the sides of the shafts with brick-work may or may not be had recourse to, in proportion to the strength of the soil, which, if good, may be supported by braces and planks only. If the places of the shafts are all marked out at the time of the tracing of the tunnel line, and sunk a small distance into the surface of the hill, they will, in the event of the bench-marks being broken down, remain as guides to the excavators.

After the work has arrived so far, and every other needful arrangement is made, in collecting machinery or removing the soil, the work should be begun by cutting down the headings on each side of the hill intended to be perforated; which should be excavated, and the soil removed, to allow of getting quite up to the approaches of the tunnel. When the approaches are made, the form of the tunnel should be traced on the section of the hill, either by a mould or otherwise. The work having so far proceeded, the perforating is to commence; and this is done by opening a communication from the first or second shaft into the ground in the line of the tunnel, and working opposite to it right and left. Preparation should now be made at the top of the shaft for raising up the soil, and this is done in several ways, the most common of which is to station at the top four or more men, standing on a platform raised three or four feet from the ground; these men turn the handle which is at both ends of a roller, and to which a rope is fastened, with a square bucket or buckets appended to each end of it; they are so regulated in size, as that two can move in the shaft or pit at once: the men in working the roller, that is by turning it round, raise one bucket while another descends, and in this manner they keep raising the soil as fast as it is excavated. In some cases, a horse-gin or turn-beam is employed, similar to those used at coal mines. As the tunneling proceeds, the upper ground should be well propped with planks, and every part secured; as the miners advance in the line. abundance of ribs also

should be prepared to turn the arch of the tunnel upon, and moulds and trammels made for the inverted arch forming the bottom.

The section of a tunnel consists in forming an inverted arch at its bottom, composed of masonry or brickwork: this arch is generally the segment of a circle, and is laid on a good bed of puddling. On the two ends of this arch rise the soffit arch of the tunnel, which in figure is commonly a simple catenaria, a parabola, or ellipse, of sufficient elevation to admit of boats riding easily through it. Plate II. fig. 4, is the section of a tunnel: A the inverted arch at bottom; B, B, the foundations of the soffit arch D, D; E the shaft or pit for taking up the soil excavated from the tunnel; F, F, the guard-rails and chock-blocks fixed to the sides of the tunnel to keep off the boats. The dotted line at C is the drain or sough to convey away the percolating waters; G the soil to be rammed in upon the soffit arch. Plate II. fig. 5, is the plan of the inverted arch to a larger scale. This arch is commonly wrought with a trammel rod, which consists, if executed in brickwork, in setting up a vertical piece of wood, to which another piece is adjusted by a centre which allows of an easy motion right and left, and describes the figure of the segment by its motion. A is the trammel rod; B the vertical shaft to which it is fixed. The trammel can be shifted at pleasure, and is an easy contrivance for forming inverted arches. Plate II. fig. 6, is the section of the soffit arch of a tunnel to a larger scale, showing it with its centering. The beam A may be fixed upon the chock-blocks previously worked into the inverted arch, at F, fig. 4. The queens D, D, may be notched into the back of the beam A, or mortised through it and wedged with sliding wedges. The strutts B, B, may be of one and a half or two inch deal, bolted with nuts and screws to the ribs G, G, and to the queens D, D. The same bolt which fastens the strutts to the ribs, may be made also to fasten the lap-joints in the ribs; the straining beam O may be in two thicknesses put on to each side of the ribs and heads of the queens, with a shoulder to the latter, and one bolt in each will suffice to fasten the whole. The meeting of the centre or rib, at the apex E, should be lapped and bolted with a nut and screw. This may be braced if required. The void F will be found useful to the workmen, in allowing them an easy access into the tunnel to notice the state of the work, and also to see if any settlement is taking place in the centering, &c., which if found weak, cross-braces may easily be fixed in it.

It is not common to make a horse-path in a tunnel, and this is one of the greatest inconveniences attending on boats passing through them, as the bargemen are obliged to scramble through as they can, by placing their hands against the walls, and pushing on their boat in any way. It would be perfectly easy to remove this inconvenience, by making the diameter of the tunnel somewhat larger, and working into the walls, one foot above the top water line, or if it were below that line it would not much signify, a number of iron brackets, projecting from the brick-work about three feet; on these brackets could be laid cast iron plates sufficiently strong to admit of horses passing over them. On the edge of this platform should be a small cast-iron rail; or there could be uprights at all the brackets, with a perforation in their tops, to admit of a rope or chain passing through them, which would act as a guard-chain or rope to the horse-path. The tops of the iron plates might be covered with a strong soil and gravel for the horses to walk upon, and thus would be removed one of the greatest defects in the navigation of a tunnel.

The centering ribs should be made in three or more parts, and they should be so adjusted together, that on the parts approaching one another they should produce the required arch, when they may be fixed with nuts and screws, taking care that the meetings be tight and close. The lower or inverted arch being turned a small way, the ribs for the soffit arch may be placed, three or four of which will be enough at a time; and these are fixed on a piece of timber called a sleeper, which is fastened at the base of the pit, and upon the chock-blocks; as the ribs are raised and adjusted to their places, their upper edges must be covered with laths to support the bricks of the tunnel arch. When the first yard of the arch is turned, the ground above the brick-work of the part formed must be well rammed and filled up, till it is as sound and firm as possible, and this must afterwards be repeated all through the work. After this is done and finished, more ribs must be placed and lathed, and the arching again begun. The workmen now look at their work with more firmness, as they see and comprehend it more completely: they begin now at each end of the already erected arch, one set of workmen working one way, and one set another, which they continue till another yard be done, which is filled up and rammed as before. It will be sometimes necessary, to avoid the effects of the percolating waters, to make at intervals, or wherever it becomes troublesome, cross-drains or soughs running quite under the tunnel, into which an opening can be made for the water to empty itself, and which may be carried off, or turned into the lower reach of the canal.

After three or more yards of the tunnel are completed, the work should be left to settle and get firm: this will be effected in a week or two, according to the state of the weather and the nature of the soil in which the tunnel has been made. If the above circumstances be at all favorable, a week will be sufficient; the nuts and screws may then be taken out of the ribs, and the first part of the tunnel centering taken down to be fixed in another part, and this may be continued all through the work, which will produce a great saving in ribs, &c. Stiff clays are the best for forming tunnels through, as they require less shoring and other supports than looser soils; in some siliceous and argillaceous soils the expences of shoring sand supporting the ground above, with the danger attending the work afterwards, is of more expense and difficulty, than at once beginning the work by open cutting, which in an instance or two has been obliged to be had recourse to, after many attempts at perforating such soils. The expense of canal tunneling, as well as others, must vary as the earth varies through which it is intended to be

made; in favorable circumstances, pretty accurate estimates might be formed; and as a reference, the following account, taken from Dr. Rees' Cyclopedia, article, Canal of the Tunnel at Blisworth, on the Grand Junction Canal, will suffice, as being one of the latest which has been finished. 'The internal width is sixteen feet and a half, the depth below the water-line to the inverted arch which forms the bottom is seven feet, and the soffit, or crown of the arch, is eleven feet above the same line. The side walls are the segments of circles of twenty feet radius, the top arch one of eight feet radius. The side, or top walls, are seventeen inches in thickness, or two bricks; and the bottom, or inverted arch, thirteen inches in thickness, or one brick and a half; every fifth course of the top arch, and every eleventh of the side walls, is composed of two heading bricks, or wedge-like, one inch thick on the inside, and three at the back; also every fifth and eleventh course as above (but between the courses of heading bricks), composed of bricks laid obliquely across the others, the front and back corners being cut off for that purpose in the making, for more effectually breaking the joints of the work obliged to be done in such short lengths. The mortar that was used was composed of one bushel of Southam lime (blue lias), and three of good sand; six inches under the water-line, on each side of the tunnel, slide-rails, of five inches square, were placed to keep the barges off the walls, and fixed by pieces of oak let into the wall below them, which rails project nine inches from the wall, and have at every nine feet a chock of wood upon the rails for the bargemen to set their pole against for shoving their barges along. It is added, that this tunnel was contracted for at £15 13*s*. per yard running. The soil, principally, through which it was made was a hard blue clay, with two or three thin rocks in it: sufficient headings had been executed several years before at the company's expense. The same contractors were paid 10½*d*. per cubic yard for excavating the deep cutting at one end of the tunnel, and 11*d*. a yard for the other. The expenses of driving the headings were from 36*s*. to 42*s*. 6*d*. per yard running; nineteen shafts, or tunnel pits, some of them sixty feet deep, were sunk for the use of the above tunnel, which cost about 30*s*. per yard in depth, including the steining.' From such data very probable estimates may be calculated, taking into account the different prices of labor and materials where such a work is proposed to be effected. The success attending tunneling having been generally complete for canals, undertakings of the same nature have been proposed for various other improvements in our inland communications. Highgate was fixed upon as one for this purpose, which certainly presented a spot in every way eligible for the undertaking, and from which the public might have derived considerable accommodation. The heading of this tunnel was begun on the Holloway side of Highgate, and extended about 350 yards with about thirty yards of vertical cutting. The whole was marl and strong blue clay, with a compactness that required very little propping; every thing in nature was favorable to the success of this tunnel, and the work went on with adequate effect till the arching commenced. It is too well known, that this arch has now given way, and it is for the engineers concerned in it to say, why.—It could not have failed by reason of the soils in which it was formed, as their compactness rendered their bearing on the arch of little or no importance. The shape of the arch made it capable of supporting ten times what was ever upon it, if the bricks had received adequate attention in their bonding. If it failed for want of sufficient foundation, it is to be regretted: the inverted arch was not adequate for that purpose, as a very slight inspection will demonstrate. And if it fell down for want of support in this quarter, it must have been from the engineers' ignorance of the nature of the pressure in such arches. Arches formed of common bricks, when they are to assume a large diameter, require the utmost attention in their construction. The brick of the common size is too small to make any figure as a voissoir in such arches, as it will not allow of falling into the radii of their curvature; if such arches exist, it is by virtue of the cement more than by reason of the shape of the materials of which they are formed. In the tunnel now making across Hyde-park, for conveying the superfluous water from the neighbourhood of Paddington, the bricks which are to form the arch are moulded into the shape of wedges, and are called joggle-bricks; the form of the joggle-brick is previously determined by drawing its shape from the centre of curvature of the arch, of which it is to form a voissoir, and they may be varied as the figure of the arch is composed of more than one centre of curvature; hence the parabolic arch will require joggle-bricks of one pattern for the top, and of another for the sides, such arch being composed of different segments.

Bridges have continued to be erected through every succession of time, and are a leading point in developing the progress of science and the arts, as they appear generally well or ill contrived in proportion as they have advanced. Arcuation, within these last fifty years, has received deductions, arising from mathematical investigations, which has ranked it very high among the late discoveries made in science. It has now been shown that the voissoirs of an arch can be given that form, in relation to the whole matter surrounding them, as to produce an equilibrated figure: and this discovery has so far extended itself as to supply the principle by a table, formed by Dr. Hutton, which sets forth its quantities to every species or degree of curvature. The bridges, to which the attention of engineers, however, is commonly called, are simple buildings, applied to the purposes of a canal; they consist, most frequently, of wood, and their beauty consists in making them light, but adequately strong.

Of the different species of canal bridges the draw-bridge is the most common; it consists of the following particulars: plate I., fig. 9, is the plan of a drawing-bridge; D the canal to be passed. The foundations, right and left of the canal, are supplied either by brick-walls, built battering, or by a row of four or more piles of oak, forced down into the embankment, with a

broad oak-rail on their tops, splayed away to receive the two end-rails of the platform of the bridge. B, B, the embankments to the bridge. G the platform of the bridge. E the vertical posts, fixed on the bank of the canal, a little behind the hinges of the bridge; on the top of these posts are two long tapering pieces F, called the balance-beams, which turn up by means of hinges near their middle, the small ends being connected with the platform of the bridge by means of chains at their further end, and which the heavy ends of the balance-beams are made to counterpoise. When such a bridge is required to be raised for a boat to pass it, it is necessary to take hold of the chains appended to the large ends of the balance-beams, which, being only just counterpoised, are easily pulled up, and when raised, the chains are hooked to the upright posts, to prevent accidents, and the bridge remains suspended.

Bridges, called swivel-bridges, are sometimes made use of on canals; they are much more expensive, and may be easily put out of order by the want of attention in using them; they consist of a platform of wood covered with planks, which is made about half as long again as is required for the bridge: one end of the platform is made light and the other heavy, for the purpose of counterpoise, and the additional weight to the heavy end is produced by means of stowing large stones or pigs of iron at it, so that the bridge, when in its place, or at rest, may attain an equilibrium. At a point of about one-fifth of its length from the heavy end, a round plate is fixed, with an iron axis or pin standing up to enter a hole in the platform, which is prepared to receive it; and on this pin the bridge is suspended, and which is also its centre of motion; and, in order to prevent impediments in turning the bridge round, a number of iron balls, two inches and a half or three inches in diameter, are let into the round plate, both above and below, to act as rollers to lessen the friction on the plates. The banks are formed with a kind of recess to receive the bridge when moved from across the canal. The two ends of the platform, in order to allow of this horizontal motion, are struck into two arcs, the centres of which are the axis or pin in the centre of the friction-plates. At Brussels, and in other parts of Flanders, they have a kind of drawing-bridges composed wholly of iron: they are made somewhat similar to our drawing-bridges, except that they are raised by a cast-iron wheel with cogs; this wheel is about three feet in diameter, and is firmly fixed in the bank, and, by being turned by a handle, raises the platform. It takes up much less room than our drawing or swivel-bridges, and answers every purpose. There are nine or ten to be seen at Brussels, constantly in motion, as ships or craft are passing up the canal. Some of these iron bridges are cut in two in the centre, with wheels in each bank, so that by working the wheels a few degrees a ship may pass the canal, by its masts entering through the space left by raising the two platforms. This kind of bridges are made necessary from the great width of the canals in comparison of ours. The occupation bridge, at Rotterdam, is of this last description, and consists of two separate segments, each supported independently; and, when up for the craft to pass, a void is made between the meetings of the segments by which the masts enter. The convenience of such bridges is obvious, as the towing can go on without removing the line; foot passengers also can pass by the bridge while in motion, as the opening between the meetings is never so wide but a person may step over it. The canals in Flanders, Holland, and every part of France abound in ingenious light bridges: their drawing-bridges are on a scale the engineers of this country have not an idea: there are some over streams 120 feet wide, moved by wheels with more ease than our little ones of twenty feet are by balance-beams.

The bridges of masonry on canals consist of one arch generally, with the difference only, of making its span as much more than the canal as to admit a towing-path under it. The towing-paths are made commonly on the lower side of the canal. The bridges over the canal at Paddington have towing-paths on both sides, and this, when there is room to do it, is a great convenience; besides adding additional strength to the abutments of the bridge. Guard-rails should be fixed to the wings and approaches of the bridge, and also to the embankments under the bridge, to keep the boats from damaging the works.

Docks, from at first being only a simple contrivance at arsenals for the purpose of building or repairing a single ship, have extended themselves to a magnitude in capacity competent to contain whole fleets. In splendor the docks created in London, and at many of the out-ports, are a monument which excel the famous port Pireus in Greece, or Alexandria in Egypt, as much, or more, than we have excelled the Greeks and Romans in all the facilities to navigation, and the grandeur of our naval architecture. The Greeks and Romans no doubt have far surpassed us in all the elegancies of taste and invention in the fine arts: in these arts they have combined and given form to matter, which could have resulted only from a higher degree of feeling, united to juster notions of nature, than the coldness of our climate and habits can perceive, or hardly give power to copy. But if we are behind in the fine arts, which, as mere copyists, we must be contented to be: in supplying all manner of facilities to commerce (in which we excel all nations, ancient and modern), in erecting the immense docks and warehouses inland, which we have done to receive and house safely the produce of the world, and to an extent adequate for that purpose, we have formed a monument at once of our genius, wealth, and skill, which will be as famous in the page of science as the monuments of Athens and Rome are now in the volume of the arts. A dock consists in the first place of a basin commensurate to its intended purpose. A canal communicates therewith, supplied with an entrance-lock and gates. The building of a dock embraces all the skill applied to buildings in water. The embankments are to be traced out in the same manner as is done for canal lines, by setting up bench-

marks to indicate the plan upon the ground. The whole of the embankments of a dock are supported by walls of masonry or brick-work; and, as the docks for ships require a great draught of water, they must be made in depth adequate to allow of ships of burden riding in them in safety: in consequence of which the depth of the docks must be great in comparison of canals. The London docks are upwards of twenty feet deep. In raising the walls on the sides of such reservoirs (as they may be called), it will be obvious that the greatest care must be taken. The foundations of walls for works of this nature should be formed of double or even treble rows of piles; and the inside row, which runs parallel to the embankment, should be grooved on their opposite sides, and be forced into the ground as close together as possible; and, after being so driven, stiles of yellow fir wrought should be driven down into the groove made in each pile, so that the whole inside piling may form a continued chain throughout its whole extent. The planking to form the platform for the wall, should be all scorched previously to being laid upon the heads of the piling, and the joints or meetings of the planking should be crossed or dove-tailed together. If the walls be to be built of bricks, care should be taken to have them of the best quality, and as square and even as can be; and, in order to strengthen their bond in the wall, tiers of Dundee granite should occasionally be incorporated. The walls themselves should be for a height of twenty feet, of fifteen bricks in thickness at the bottom, on planking racking-back on the side next the earth embankment, and battering on the inside of the dock, with tiers of bond of Dundee granite at every twentieth course throughout the height. The slope of the wall should be in proportion to a scale before recited for lock-walls of canals; and a curvature or swell should be formed in the inside section of the wall in the proportion of two inches to every six feet: the walls should, finally, finish at their tops to four bricks in thickness, and the whole be crowned by blocks of Dundee or other granite, as a coping. The mortar used for these kinds of works ought to be particularly looked after, in order to its being of good quality, or very little solidity will result to the work. The ground stone lime with washed siliceous earth, the former as fresh as possible, is the most likely to prove a good cement. The Roman cement, or Parker's, is of great utility in some parts of dock-works. The docks, as Helvoetsluys, are formed with clinkers cemented by Dutch tarras: it has tiers of bond traversing at every four feet, vertically, composed of black marble neatly wrought, which in every other stone goes quite through the wall, and the top of the wall is coped with large slabs of the same marble. The work of these docks from the smallness of the bricks (about six inches long, three in width, and one and a half inch in thickness), and the joint having very little cement in it, makes the whole appear uncommonly neat, and which is not less solid. These docks are, about eighteen feet perpendicular in depth, the side slopes from their base five feet eight inches. The opposite end to the canal of communication is formed into a bow or crescent. The walls all round this dock have a slight swell or curvature in their height. The canal leading to a dock generally branches out of its side, and is walled in a similar manner to the dock itself, and at its upper end or head is contracted by the walls being bent into a circular shape till they meet or intersect the wing walls of the lower end of the chamber of the lock. The lock is the pound or chamber through which the ship or ships enter from the sea or river to which the dock is contiguous: to docks of consequence the locks are made from thirty to forty feet wide, about eighteen feet deep, and 150 feet long. They have gates at both ends, which require the utmost skill in contriving them for tidal-rivers. The bottom of the lock is formed by an inverted arch of masonry in a similar manner to that of canal-locks, except on a larger scale, and of course of a more ponderous nature. The walls are raised battering similar to those of the docks, and, finally, coped at their tops, weirs, syphons, waste-gates, and culverts, are all of use to dock-work, and must be called in as the nature of the situation requires them Wherever it is intended to form docks a large site of ground should be selected, in order to admit of abundance of room for all kinds of stowage and warehouses being built thereon; for without abundance of room very little accommodation can be expected by creating docks on such sites. The necessity of room in such concerns will more obviously appear by considering the space occupied by the docks themselves in the three great concerns now effected in London. See Docks.

After docks, there is another appendage equally flowing from our great maritime power, and which consists in creating artificial piers or break-waters, projecting into the sea for the purpose of giving security to vessels at anchor against the violence of winds and currents, at such places where it has been deemed eligible to form ports or places for ships to anchor at. The late Mr. Smeaton was the first engineer amongst us who embraced, in the boldness of his genius, the requisite science for such undertakings, which has had the effect of establishing his reputation beyond the chance of a failure. Every part of the country exhibits something of his contrivance, either in canals, bridges, harbours, or machinery; and, of course, every thing from such authority is of importance, inasmuch as it may teach those who have now to follow him how true fame may be acquired and become imperishable.

It is extremely difficult to give precise ideas for buildings connected with sea-ports and their harbours; for in such places the natural vicissitudes are what offer the impediments, and they must be met, in the various ways in which they present themselves, by the skill and enterprise of him to whom such buildings may be confided. There have been piers or break-waters erected at many of our ports extending an immense distance out into the sea; for instance, at Sheerness, Ramsgate, &c.: and there have been also several on the opposite coast; the one at Cherbourg is pre-eminent, for boldness and genius. See Cherbourg. Some account of Mr. Bentham's plan, adopted at Sheerness Pier,

will be seen under the head of Buildings in Water, in our article Masonry. The great national work in Plymouth Sound is perhaps on a scale far beyond any thing of the kind ever set about in the world before. We have happily to record its completion. See our article Plymouth.

The erection of beacons and light-houses is a branch of the royal prerogative. The king has the exclusive power, by commission under his great seal. He can order them to be erected, not only upon the royal demesnes, but upon the lands of the subject; which power of the crown is usually vested, by letters patent, in the office of the lord high admiral. And if the owners of the land, or any other person, shall destroy them or take them down, he shall forfeit and pay £100, and in case of inability to pay it, be ipso facto outlawed. By statute, 8 Eliz. c. 13, the corporation of the Trinity House were empowered to set up any beacons or sea-marks wherever they might think them necessary, and in them now almost the whole business, respecting the management of beacons, light-houses, &c., is vested. The beacon is a simple contrivance, of very early origin, as we find frequent mention made of such objects, not only in the Scriptures, but in ancient history, and particularly in the early part of our own. Beacons consisted chiefly in erecting on high places marks whereon were fixed barrels containing pitch or other combustible matter, which, by night operated as a warning, by being lighted, and by day they gave notice of the approach of an enemy, by the volumes of smoke emitted. By the discovery of gunpowder, such expedients have been discontinued; as rockets and other contrivances are found to answer the purpose infinitely better. A light-house is a different kind of building to a beacon, inasmuch as it requires greater constructive excellence in the erection. Its use is chiefly to warn mariners, when navigating in the night, from approaching too near certain parts of the coast known as dangerous, either by rocks, shoals, or currents; and it is also a land-mark by day. These structures are of great national importance, and, as such, cannot receive too much attention, either in forming them in the most substantial manner, or supplying them with the best lights. A light-house, as now erected, consists of an upright shaft of masonry or brick-work, built hollow in the inside, in which are winding stairs leading to its summit. The top is generally surmounted by a cornice of stone, with a space left sufficiently large to admit a single person safely to walk round upon it. On the top of the whole fabric is erected a lantern, often from twelve to fourteen feet high, and six or seven feet in diameter, in the inside of which is a frame, to which are suspended, in various angles, and in as many elevations, a number of lamps and reflectors; the lamps vary from ten to as many as fifteen in some light-houses. Such a body of light and that reflected with the greatest power on an immense height, as they most frequently are, creates a surprising effect, which is discovered at sea by mariners when many leagues off, and which enables them to shape their course accordingly.

The Eddystone light-house was erected by the late Mr. Smeaton, and in this is employed, perhaps, more ability than in any similar structure in existence, arising out of the difficulty of erecting any thing in such a perilous situation. Mr. Winstanley began a light-house on the Eddystone rock in 1696, which he was four years in finishing, which was formed wholly of wood. The following notices respecting his operations may not be unacceptable. The first summer was spent by Mr. Winstanley and his people in making twelve large holes in the rock, and fastening as many irons, to hold the future work. In the course of the next summer, a solid body or round pillar, twelve feet high, and fourteen feet in diameter was completed. In the third year it was increased to sixteen feet in diameter from the foundation, and the whole building was raised, which was eighty feet to the vane. In the fourth year, the diameter of the pillar was encompassed in a new work, four feet in thickness, and the building raised forty feet higher when the light was exhibited. This building was formed almost wholly of timber, and it did not meet with any accident till 1703, when standing in need of repair, Mr. Winstanley came to see it; and having been among his friends previously to going off with his workmen, to view the repairs, the danger was intimated to him, and that one day or other the light-house would certainly be overset: he replied, 'He was so well assured of the strength of his building, he should only wish to be there in the greatest storm that ever blew under the face of the heavens, that he might see what effect it would have on the structure.' Mr. Winstanley was but too amply gratified in his wish; for while he was there with his workmen, that dreadful storm began, which raged the most violently upon the 26th of November, 1703, in the night; and of all the accounts of the kind with which history furnishes us, we have none that exceeded this in Great Britain, or was more injurious or extensive in its devastion. The next morning, November 27, when the violence of the storm had in some measure subsided, so that it could be seen whether the light-house had suffered by it, nothing appeared standing, but, upon a nearer inspection, some of the large irons whereby the works were fixed upon the rock; nor were any of the people, or any of the materials, ever heard of afterwards.

The next light-house, built on the Eddystone, was by Mr. Rudyerd: it was finished in 1709, and destroyed by fire in 1755. It was now deemed eligible to erect a superior building, if possible, and one not so likely to meet its destruction, either by the violence of the sea, or the effect of fire, as both the former had been destroyed by one or the other. Mr. Smeaton was employed, and, contrary to the received and popular opinion, that no building could be made to stand except one formed of wood, he showed a contrary design, and boldly projected a lighthouse of stone. He himself says, 'he shall endeavour so to form it and put it together, that, by a similarity of construction, no man shall be able to tell him at what joint it should overset; for if at any given height the

uppermost course was then completed safe, it became more safe by another course being laid upon it; and though that upper course were somewhat less in weight, and in the total cohesion of its parts, than the former, yet every course, from the first foundation, was less and less subject to the heavy stroke of the sea.' This building was formed to resist the effect of both wind and water, and these acting on it occasionally in a most tremendous way. The light-house is wholly of cut-masonry, about sixteen feet in diameter at bottom, and diminishing upwards conically; it is seventy-three feet six inches in height, measuring from the rock on which it stands to the top of the cornice. Mr. Smeaton chose a curve for this structure with its concavity turned outwards, and the judiciousness of such a choice is now fully established. From the top of the cornice to the base of the lantern is seven feet six inches, and from thence to the summit of the ball seventeen feet six inches, which, together, make a total height for this structure of ninety-eight feet six inches. See also Bell Rock Light-house.

The form of such buildings has involved considerable intricacy of mathematical investigation. M. La Grange has calculated that a cylinder is the strongest form for resisting flexure, which is contrary to the known fact, and could be only deduced from the intricacy of the investigation. If it were calculated what would be the best form for a wooden column, which to a certain depth was always to remain exposed to the water, it would be found that a cone or pyramid would possess the greatest possible strength for supporting the pressure of the water; and for resisting the wind also, the figure must be made more acute than it would otherwise be necessary for resisting the water only. The Plymouth break-water has justly been considered as one of the finest pieces of hydraulic engineering in existence. It is about one thousand seven hundred yards in length, and the principle on which it is made to resist the operation of the waves is shown in our plate Break-water, fig. 3. It consists of an inclined plane, formed of loose stones thrown promiscuously from the flat-bottomed vessel fig. 1. A large block of about ten tons is there shown in the act of being discharged from the platform. An enlarged view of the carriage and platform is given at fig. 2.

The forming of roads is of considerable importance to every well regulated country; and although it has been, perhaps, too much neglected in our own, it is now receiving that attention which its importance requires. We shall devote to the important subject of high roads, a separate article, embracing the latest improvements. See Roads.

The origin of iron or rail-roads may be traced back to the year 1680. About that period coal came to be substituted for wood as fuel in London and other places: the consequence was, that at the mines the greatest inconvenience accrued in conveying the coal from them to the ships, as well as immense expense in horses and machinery for the purpose; to remove which, waggon roads were made, consisting of wooden rails or ledges, which the waggons were formed to move upon, from which improvement it was found that a single horse could easily draw a waggon on these rails, which previously required three or more horses to be employed to effect by the common roads; and it was also drawn more quickly, arising fromlaying down the frames upon an easy descent, which was always done.

In 1738 this invention was farther improved by substituting cast-iron rails instead of the old wooden ones; but owing to the old fashioned waggons continuing to be employed, which were of too much weight for the cast-iron, they did not completely succeed in this first attempt. However, about the year 1768, a simple contrivance was attempted, which was to make a number of smaller waggons and link them together; and, by thus diffusing the weight of one large waggon into many, the principal cause of the failure in the first instance was removed, because the weight was more divided upon the iron. In 1797 these roads having impressed the minds of intelligent men as of great importance, numerous essays appeared, setting forth their utility, and as many plans for rendering them of permanent construction. See Dr. Anderson's Recreations, Nicholson's Journal, Repertory, &c. &c. Hence cast-iron rail-roads became a second desideratum to canals, excepting only that the invention is due to Englishmen. After this time the cast-iron rail-ways began to be constructed as branches to canals, and in some places as roads of traffic from one place to another, established upon permanent principles, so as to produce a permanent revenue to the undertakers. In surveying a line to set out a rail-way upon it will be necessary, as a preliminary step, to ascertain, as accurately as the nature of the thing admits, the quantity of lading expected to traverse each way upon its line; because in forming the slope or descent, this will be the datum on which to ground a medium for effecting the required purpose most easily. If it should turn out that as much lading is expected one way as the other, with a preponderance at periods only, the railing must in such a case be set out in levels or in lines nearly level, and the ascents and descents made by planes inclined accordingly. Previously to beginning any part of the work, that is of laying the sleepers, &c., for the iron-rails, a rough sketch or section of all the different routes intended to be passed by the rail-way should be made; from which, and a view of the ground, the engineer will be enabled to determine the place, and also the extent of the inclined planes which will be required in passing the steeper parts or the rising ground to which these planes are to be employed: it will always be desirable to get them as short as the site of the place will admit. In tracing out the line of a rail-road, the following method is pursued by our best engineers: they begin at the highest point, using a chain (of 100 links), and also berms, or bench-marks, and targets, as they are called. The chain is stretched out upon the ground, one end being held at the point of the deepest turn, and the other turned round upon the face of the descent, until a point

marked by this end is found, which is one link lower than the upper end, or nearly so. The chain is still carried forwards till its hinder end reaches the point last determined. The other end is then moved, and another point is ascertained one link lower than the last, and the operation is so continued, by which a line having the regular descent of one link to each chain will be traced out on the site of the intended rail-road. The bench-marks are to be put in at each successive observation to mark the place found, and if it turn out irregular and crooked, the operation must be again repeated till the line appear more regular and without any sudden bends or crooks which must be always removed and made undulating and easy, as it will prevent unnecessary friction in the wheels of the carriages against the ribs of the rails. The rail-road when first marked out has a stake or mark set up at every chain in length, and these marks are the guides by which the workmen begin the operation of putting down the roads. When sudden valleys present themselves, approaching to higher ground, it will be necessary so to conduct the line as to cut into the hill at each side, and the cutting from the latter will be useful in raising the road-way of the former. On approaching rivers or brooks which it is determined to pass, it will be necessary to keep up the rail-road to a higher level by embankments, and on passing the water to raise a platform on purpose for it, composed of piers of masonry or columns of iron, with a covering of iron also to receive the rails; or a bridge, similar to an aqueduct bridge, will answer the purpose. Rail-ways may be divided into single and double: by the former it is understood that a single road only is to be formed; by the latter, that two or more are to be made for the ready passage of waggons up and down the road. Single roads are generally made, including horse and attendant paths, four yards wide; and double ones vary from six to eight yards wide, exclusive of all the common appendages to such roads of drains, fences, &c. &c. In forming permanent rail-ways stone-sleepers are necessary. These consist of pieces of good sound free-stone, with their upper faces wrought fair, and should weigh from 150 to 200lbs. each, with their ends, which come together wrought smooth, so that the joints may be firm and close. The work of setting the sleepers must commence as soon as the road has received a tolerable surface in point of regularity. In cases in which there has been much making up or embanking the ground, short piles (as shown plate 2, fig 7, B, B,) should be driven down to receive the stone sleepers, taking care to let the head of the pile come exactly under each meeting or joint of the stone-sleeper.

In commencing the work of laying down the stones, great exactness will be necessary in order to the iron-rails lying firmly on them; when one of the stone-sleepers is laid in the proper place for one side of the rail-way, and nicely bedded and rammed down, another is to be laid at four feet distance from it, and bedded in a similar way. When these two stones are laid, they will operate as guides for proceeding in laying more stones, right and left, which should be carried forward together. A,A, plate II. fig. 7 represent the stone-sleepers: B,B, the piles or blocks for supporting the sleepers in infirm ground; C,C, the sections for the cast-iron rails. Every tram or rail-road must be provided with passing places; a passing place consists in forming large plates of cast-iron, in such a manner as to admit of common rails being joined to them, and which will allow the waggons traversing the road to pass off into another or adjoining tract. Plate II. fig. 8, shows a passing place for a double rail-road drawn to a quick sweep: but the turning or passing place need not be of such acuteness in general, but may follow a more obtuse shape, as best suits the nature of the place to be passed. Plate II, fig. 8; represents the plan of the two meeting cast-iron plates, D, D; these plates should be accurately modelled in wood for the founder; and they should be so adjusted as that one model may serve for as many passing places as possible on the line of the proposed road; F, F, shows the joints where the common rails meet the passing ones; E, E, are moveable iron tongues placed in the centre of the passing plate, D D; which allow, by turning them round on a centre, of being removed to either side of the plate to keep the wheels of the waggons in the tract required; so that a waggon may go on either side of the road by putting the tongue in the opposite direction. The side rails are shown at G, G; these consist of common side rails, except only that they must be modelled and founded to the intended shape of the passing place. H H shows the horse-path of the rail-road at the passing place. Plate II. fig. 9, exhibits a single length of a common rail for a road, with its projecting margin, K, to keep the waggon wheels in the tract; as also the grooves, I, I, through the ends or meetings to allow of their being fastened to the stone sleepers. The common method of fastening the cast-iron rails to the stone-sleepers, consists in previously making in the stone an octangular perforation opposite to every joint intended in the cast-iron rails, into which a trunnion of good sound oak is fitted, with the grain of the wood presenting its section uppermost. The perforations to receive the oaken trunnions should be made quite through the stone, in order to prevent the effects of the frost, which, if not through, the water lying in the hole will become frozen, expand, and shiver the stone into pieces. When the iron rails are nicely arranged upon the bearers or sleepers, they are to be fixed down by driving an iron key pointed at its lower end, so as to allow of its being driven into the oaken trunnion; the iron key has a head projecting similar to the letter T: and its lower shaft is made exactly in size to fill the void or groove left in the ends of the iron rails, as shown at I, I, fig. 9. The common cast-iron rails for roads are formed in lengths of about three feet each; they are made about four inches wide upon the flat, or that part intended for the wheel of the waggon to move upon, and which is about one inch in thickness, sloped off a little to the horse-tract: the projecting rim rises two inches and a half from the flat or bottom of the rail; in its centre forming the segment of a circle projecting

upwards about an inch only at its meetings (See fig. 9). The cast-iron plates at the passing places should be made somewhat stronger than the common rails, as at the passing places there is the greatest wear and tear upon the whole line. The iron moveable tongues E, E, fig. 8, should be of wrought iron, and made about two feet six inches or three feet long, standing up upon the plate equal in projection to the highest part of the rim, K, of the common rails. It should be on a good strong axis or pin, that it may be strong and yet allow of being easily turned round, which it will require to be every time the waggons are passing by the different tracks up and down the rail-way. In passing deep descents, pieces of cast or wrought iron must be provided, called sledges or slippers; these are provided to be placed under the wheels of the waggons, to prevent their too rapid descent, and are similar in principle to the same kind of instrument made use of, and appended to our road-waggons, for putting under the wheels on their going down a hill. When the whole iron rail-way is fixed, and levelled to the satisfaction of the engineer, it will be necessary to begin to prepare the horse and attendant paths; the foundation of the former should be, if possible, composed of good lime-stone, broken into small fragments, and strewed to the consistence of at least from ten to fourteen inches in thickness, rather convex towards the centre of the path, upon this large screenings of gravel should be laid: the attendant path should be firm and regular, with a gravelly surface. The horse-tract and rails ought to be always kept clear and free from soil, which is constantly collecting on rail-roads of great traffic; and they ought also to be properly drained and kept dry at all seasons of the year; as on this, in a great measure, will depend their substantiality, and of course their utility.

With respect to the waggons employed on iron rail-roads, those in most general use are so constructed, that their weight, including their lading, does not exceed three tons and a quarter. This is found by experience to be the most eligible size: as the rail-roads retain their shape without much dilapidation, by the use of waggons equal to such weight. The wheels of the waggons are made of cast iron, two feet five inches high, having twelve spokes, which increase in width as they approach the hub, or centre of the wheel. The hub is eight inches long, and receives an axle of wrought iron. the rims of the wheels are two inches broad. The axles of the wheels are fixed at two feet seven inches distance from each other; the bodies of these waggons are seven feet nine inches long, four feet five inches wide, and two feet four inches deep; and this sized waggon is calculated to contain the quantity of coal, or other matter, equivalent, with the waggon added to it, to make a weight altogether amounting to three tons and a quarter, as before stated, as the most eligible weight to move upon a cast-iron rail-road. In the Philosophical Magazine, July, 1811, are the following remarks concerning waggons, and also rail-roads, from which some idea may be formed of the utility of such roads. The waggons on our cast-iron rail-roads, have not received the improvements of which they are capable; but, with their present disadvantages, the following facts will evince the great saving of animal force to which rail-ways have given rise: First, with a declivity of one inch and a quarter per yard, one horse takes downwards three waggons, each containing two tons: second, in another place, with a rise of one inch and six-tenths per yard, one horse takes two tons upwards. Third, with eight feet rise in sixty-six yards, which is nearly one-fourth of an inch per yard, one horse takes two tons upwards. Fourth, on the Penrhyn railway (same slope as above), two horses draw downwards four waggons, containing one ton of slate each. Fifth, with a slope of fifty-five feet per mile, one horse takes from twelve to fifteen tons downwards, and four tons upwards, and all the empty waggons. Sixth, at Ayr, one horse draws on a level, five waggons, each containing one ton of coal. Seventh, on the Surrey rail-way, one horse, on a declivity of one inch in ten feet, is said to draw thirty quarters of wheat. From these cases, and the known laws of mechanics, we may, perhaps, safely infer, that where the apparatus is tolerably good, and well constructed, and the slope ten feet per mile, two horses may draw five tons upwards, and seven tons downwards.

In cases in which inclined planes are to be had recourse to, to carry the rail-road over high grounds (and there are several now passing such ridges), the mode pursued in raising the waggons may not be unacceptable. The common plan is by a perpetual chain suspended at each end: it is so contrived, that the waggons disengage themselves the moment they arrive at the upper or lower extremity of the inclined plane. In some cases, the laden waggons descending, serve as a power to bring up the empty ones; but where there is an ascending as well as a descending traffic on the rail-way, steam-engines, water-wheels, or other machinery, to answer the same purpose, are used. 'At Chapel le Frith, there is an inclined plane of 550 yards. On the proposed rail from Glasgow to Berwick several inclined planes will be required, the summit of that rail-way being 753 feet above the level end of Berwick quay.' As to the expense of rail-ways, they are inconsiderable, in comparison of canals. According to Mr. Fulton, 'the cost of a single rail-road, with sufficient crossing places for a descending trade, was estimated at £1,600 per mile.' In Dr. Anderson's recreations, £1,000 is mentioned as the estimate for a double one. However, Mr. Fulton's is most likely to be the nearest to accuracy, as his calculations were made from actual observation, and embraced the whole minutiæ of such a work.

The principal rail-ways in England and Wales are the Liverpool and Manchester, thirty miles in length, which is just completed; the Cardiff and Merthyn, twenty-six miles and three-quarters long and runs near the Glamorganshire canal; the Caermarthen; the Sexhowry, twenty-eight miles, in the counties of Monmouth and Brecknock; the Surrey, twenty-six miles; besides several in the north of England.

**ENGIRD'**, *v. a.* En and gird. To engird; encircle; surround.

> My heart is drowned with grief,
> My body round *engirt* with misery;
> For what's more miserable than discontent?
> *Shakspeare.*

**ENGIRT'**, *v. a.* En and girt. To encircle; environ; engird.

> That gold must round *engirt* these brows of mine.
> *Shakspeare.*

> So white a friend *engirts* so white a foe. *Id.*

# ENGLAND

ENGLAND, Lat. Anglia, the southern and most important division of the island of Great Britain, is of a triangular form; and from the south Foreland in Kent, which is the eastern point of the triangle, to Berwick-on-Tweed, which is the northern, its length is 345 miles; from that point to the Land's End in Cornwall, which is the western point of the triangle, it is 425; and the breadth thence to the south Foreland is 340 miles. Its superficial extent is estimated at upwards of 50,000 square miles, or above 32,000,000 of statute acres. England is bounded on the north by Scotland, north-east and east by the German Ocean, south by the English Channel, and west by St. George's Channel, the principality of Wales, and the Irish Sea.

England contains forty counties, twenty-four cities, 160 boroughs, two universities, and eight cinque-ports. Wales has twelve counties and fourteen boroughs. The counties return 158 knights; the cities fifty citizens; the boroughs 335 burgesses; the universities four representatives; and the cinque-ports eight barons to parliament. The circuits of the judges, six in number, are called, the Home circuit, the Norfolk, the Oxford, the Midland, the Western, and the Northern circuits. Middlesex, Chester, and the Isle of Ely, were not included in these circuits. The two grand ecclesiastical divisions, or provinces, are those of the archbishoprics of Canterbury and York.

We should not here perhaps pass over, without some notice, the circumstance of several of the counties having certain portions detached, and surrounded by districts belonging to other counties. This is the case in the following instances: Shilford, which is a political and statistical part of Berkshire, is actually in Oxfordshire; as also is Langford, belonging to the same county; and on the south-western borders of Berks, this county and a portion of Wiltshire are intermixed, near Titcombe and Oxenwood. Northamptonshire on the southern border contains a portion of Buckinghamshire: and Caversfield, in this latter county, is involved in Oxfordshire. The southern and south-western districts of Gloucestershire are so intermixed with the north-eastern portions of Somersetshire as often to create considerable difficulty in discriminating them; while Holwell, which belongs to Somersetshire, is some distance in the county of Dorset. Gloucestershire has likewise a portion situate in Wiltshire; this is the case with respect to Myntey. Cascob, encompassed by parts of the county of Radnor, the Futhog Hills in Monmouthshire, and Farlow and the Clee Hills in Shropshire, all belong to the county of Hereford. Coleshill Green, belonging to Herts, is surrounded by parts of Buckinghamshire. Everton, belonging to Huntingdonshire, is actually in Bedfordshire. The parish of Lillingstone Lovell, in Oxfordshire, lies within the county of Northampton; as also does Boycot, likewise a part of Oxon. The reader, in casting his eye over the map of Shropshire, will also be struck with the singular appearance of Hales Owen and the Leasowes being in Staffordshire, together with the hamlet of Oldbury, belonging to the parish of Bridgenorth in the hundred of Stoddesden. Staffordshire also appears to have taken a portion of Worcestershire; while this county engrosses a portion of its neighbouring province Warwickshire; and Warwickshire again contains part of Worcestershire. Part of Wiltshire is in Berks. Lastly, the county of Worcester seems singularly insulated by a portion of Gloucestershire; and parts of Herefordshire are encompassed by the western boundaries of Worcestershire. The Isle of Thanet it is well known is a part of the county of Kent.

The reader is referred to our article Britain, for the general statistics of the island and its political history to the period of the final settlement of its Saxon conquerors here, under Egbert. We now resume the statistics and the history of England, distinctly considered, until the latter merges in that of Great Britain under king James I.

## PART I.

### STATISTICS OF ENGLAND.

England, in its general appearance, as in its size, claims the palm of superiority over the rest of our island. It is far more minutely cultivated than either Scotland or Wales. There is no topic on which an Englishman may more proudly exult than the scenery of his native country. If, in particular points of natural grandeur, other countries, and even other parts of Great Britain, may outvie England, she presents a union of the agreeable with the grand and imposing, of the confirmed works and triumphs of art, with the magnificence of nature, no where else to be found. We are not destitute of the lofty mountain, the craggy rock, and the dark moor, as an occasional contrast to scenes more attractive in their individual features. We have also our architectural antiquities, great in ruin, and still greater in the moral and patriotic associations connected with them. But in the gentle undulations of hill and vale, crowned with wood, fertile in corn, or overspread with cattle; in the high cultivation and elegant disposition of our scenery, we are unrivalled. No where is there such a source of scenic beauty in rural and general opuence.

In our article Britain we have noticed the great mountain ranges of England. Of about

seventy forests, mostly planted by the first Norman kings, not more than four remain: Windsor, New Forest, Dean Forest, and Sherwood Forest; and there are now scarcely any woods which do not belong to some nobleman's or gentleman's seat, or are not attached to some of the royal palaces. Neither is the face of the country so much diversified with lakes, meres, or fens, as formerly. The district now most properly designated as the Fens is comprised in the contiguous parts of Northamptonshire, Lincolnshire, Cambridge and Huntingdon, with the northern borders of Norfolk and Suffolk. But the improvements in agriculture, and the practice of drainage in general, have converted numerous extensive portions of fenny and marshy districts into arable land. There are, however, several beautiful and extensive lakes; particularly those of Cumberland, Westmoreland, and Lancashire, which are not exceeded, in extent or picturesque effect, by many others in the known world.

Espriella, speaking of the small but exquisitely beautiful lake called Brotherwater, remarks, 'I have never seen a single spot more beautiful or more rememberable. The mountain behind it—is one of the highest in the country, and forms a cove, in which a single old mansion stands in a green field among old trees. The most rigid Jeronymites could not wish for a place of more total seclusion. Out of this lake flowed a little river, clear, rapid, and melodious; we crossed it, and our path lay along its banks. How often did I stop and look back, and close my eyes to open them again, as if repetition could better impress the landscape upon remembrance than continuity! The delight I felt was mingled with sorrow by a sense of transitoriness;—it was even painful to behold scenes so beautiful, knowing that I should never behold them more.' We must allow this pseudo-traveller, but real poet, to describe another of our lakes: that of Keswick. 'There is something in this place,' says he, 'more like the scenes of enchantment in the books of chivalry than like any thing in our ordinary world,—a building, the exterior of which promised all the conveniences and elegancies of life, surrounded with all ornamental trees, in a little island, the whole of which is one garden, and that in this lovely lake, girt round on every side with these awful mountains. Immediately behind it is the dark long western mountain called Brandelow: the contrast between this and the island, which seemed to be the palace and garden of the Lady of the Lake, produced the same sort of pleasure that a tale of enchantment excites, and we beheld it under circumstances which heightened its wonders, and gave the scene something like the unreality of a dream. It was a bright evening, the sun shining and a few white clouds hanging motionless in the sky. There was not a breath of air stirring,—not a wave, a ripple, or wrinkle on the lake; so that it became like a great mirror, and represented the shores, mountains, sky, and clouds, so vividly that there was not the slightest appearance of water. The great mountain-opening, being reversed in the shadow, became a huge arch, and through that magnificent portal the long vale was seen between mountains, and bounded by mountain beyond mountain: all this in the water, the distance perfect as in the actual scene,—the single houses standing far up in the vale, the smoke from the chimneys,—every thing the same, the shadow and the substances joining at their bases, so that it was impossible to distinguish where the reality ended and the image began. As we stood on the shore, heaven and the clouds and the sun seemed lying under us; we were looking down into a sky, as heavenly and as beautiful as that over head; and the range of mountains, having one line of summit under our feet and another above us, were suspended between two firmaments.'

The most extensive plains of England are, as we have noticed, in the eastern and southern shores of the island. The great centre plain spreads from the banks of the Thames to those of the Humber, and even beyond that river. It therefore includes a great part of Essex, Suffolk, and Norfolk, with the margins of the bordering counties; thus embracing nearly the whole eastern side of England. The Wealds of Kent, Surrey, and Sussex, form another extensive plain, stretching from Ashworth, in the first county, to Petworth in the last; and separating the South Downs, and the northern range of chalk hills in Surrey and Kent. Its length is between sixty and seventy miles, and its surface about 1000 square miles. The wide-spread district, called Salisbury Plain, is an open country, resembling the Sussex Downs.

The principal vales of England, denominated after its greater rivers or towns, and the scenes of its greatest fertility, are, beginning northward, those of Carlisle in Cumberland, encompassing that city; that of Coquet, in Northumberland, through which a river of that name flows, and greatly noted for its agricultural luxuriance. The vale of the Tyne, in the southern part of the same county, richly and beautifully variegated. The vale of Stockton, embracing both banks of the rapid Tees. The vale of York, one of the most extensive and fertile in the kingdom, containing 12,000 square miles of surface, intersecting that county from north-west to south-west, is separated from the vale of Stockton by a narrow district of almost imperceptibly rising ground. It stretches thence to the Humber, and is refreshed by the numerous rivers and streams which are tributary to the northern Ouse. This luxuriant vale abounds in timber, and affords ample returns of agricultural products. A branch watered by the river Derwent, diverges towards the north-east, and separates the Wolds from the eastern Moorlands. The vale of the Mersey includes the margins of Lancashire and Cheshire; while much of the central regions of this last county form that of the Dee. The valley of the Severn is an extensive tract of rich land, commencing near the borders of Wales, and, traversing Monmouthshire, Shropshire, and Gloucestershire, is divided by slight elevations into the district of Worcestershire, and the vales of Gloucester and Evesham. A great proportion is appropriated to pasture.

In the west of England, the most attractive vales are those of Exeter and Taunton: the former, stretching from the Tiverton hills to the sea

is watered by the rivers Exe and Otter; and comprises about 200 square miles: the latter, separated from that of Exeter by a ridge of high land, extends in an opposite direction to the Bristol Channel. Aylesbury stands in a vale, abounding in rich pasturage, and watered by the Thames as it flows through Buckinghamshire. The Trent also has its vales, particularly in that part of the county of Nottingham which borders on Lincolnshire and Leicestershire.

The rivers of England have been enumerated in the article BRITAIN; more particular descriptions of their courses belong to their respective places in the alphabet: and the canals of this country form a large feature in our article INLAND NAVIGATION.

No country is richer, for its size, in mineral waters. Those of Bath, Buxton, Bristol, and Cheltenham, have already fallen under our notice: Harrowgate, Matlock, Scarborough, and Tunbridge Wells complete the catalogue of the principal ones, and will each be found distinctly treated. At Gloucester a chalybeate spring has recently been discovered, more strongly impregnated than either those of Cheltenham or Leamington. We must not omit to notice the aluminous chalybeate water of the S. S. W. of the Isle of Wight. This contains sulphate of iron and sulphate of alumen: there are also some portions of carbonic acid gas, sulphate of lime, sulphate of magnesia, sulphate of soda, muriate of soda, and silicia: but these ingredients are rendered wholly imperceptible to the palate by the superior portions of iron and alumen. These impregnations are much stronger than are to be met with in any other mineral water of England; and even than those of Hertfell-water in Scotland. The sulphureous waters of Gilsland, in Cumberland, consist of muriate of soda, sulphureted hydrogen gas, azotic gas, and carbonic gas. The saline waters of Leamington Priors, in Warwickshire, are also in considerable repute and much frequented. The medicinal springs issuing from the Malvern Hills in the counties of Worcester Gloucester, and Hereford, are of various qualities; but principally chalybeate. They do not contain any uncombined vitriolic acid, volatil alkali, or metallic salt; but are slightly impregnated with fixed air, some common air, selenites, and a little unneutralised calcareous earth.

There is a chalybeate spring at Southampton, at the bottom of Orchard Street, resembling that of Tunbridge Wells. The component parts are steely particles, marine salts, an oily matter, an ochreous substance, a volatile vitriolic spirit, too subtile for analysis, and a simple fluid. The Nottington mineral spring, near Weymouth, contains hepatic, phlogisticated, and fixed air, the digestive salt of Sylvius, vegetable alkali, magnesia, &c., and strongly resembles the Moffat water in Scotland.

Of the ever-varying but healthy *climate* of this country we have observed that July and August are its warmest, and December and January its coldest months. In the former Fahrenheit's thermometer seldom rises above 85° or 86°, the general maximum of the year being 81° or 82°; and in the latter it seldom sinks lower than 14° or 15°, though it has been known to descend below 0°. The thermometer has been long supposed to attain the greatest height a little west of the metropolis; but this, as we shall presently show, is a mistake. The north-eastern counties are subject to a greater degree of cold than those on the north-west. The north and south of England differ less in the temperature of winter than in that of summer. The greatest and least heights of the thermometer, at the following places, have been thus given:—

| | Liverpool. | Middlewich. | Lancaster. | London. | Dover. | Sidmouth. | Derby. |
|---|---|---|---|---|---|---|---|
| Greatest height | 86° | 78° | 82° | 81° | 86° | 76° | 78° |
| Least height | 22 | 21 | 18 | 20 | 16 | 20 | 19 |

The following is another calculation of the mean temperatures of London and York, reckoning the spring to begin with March and end with May, and each of the following seasons to contain three months.

LONDON.

| | |
|---|---|
| Spring | 46·2 |
| Summer | 62 |
| Autumn | 59·4 |
| Winter | 40·5 |
| Annual mean | 51·9 |

YORK.

| | |
|---|---|
| Spring | 42·6 |
| Summer | 63·3 |
| Autumn | 56·3 |
| Winter | 36 |
| Annual mean | 49 |

Dr. Young states the mean temperature of the six winter months, from October to March, inclusive, at London, to be 43·5°; while at Dawlish, on the south coast of Devonshire, it is 45·3°, and at Ilfracombe, on the shore of the Bristol Channel, as high as 59°. From November to March the mean temperature, at London, is 42·6°; at Penzance, in Cornwall, 48·1°. From January to March, at London, 37·9°; at Penzance, 48·5°; and at Sidmouth, in Devonshire, 41·7°. During February and March, in the metropolis, 41·5°; at Clifton, 42·6°. From October to December, in the capital, 47°; and at Sidmouth, 45·7°. In the most sheltered parts of Devonshire the mean winter temperature exceeds that of London by about 1·5°; while, during the coldest months, the temperature at Penzance is, according to this writer, higher than at London by 4·5°.

Mr. Howard, who has directed his particular attention to the climate of London and its neighbourhood, observes, in regard to the law of temperature in such climates as ours, that it is probable the mass of air is similarly affected by the sun's rays, and that the proportion of heat

which it derives from the direct passage of the rays is the same in all seasons. 'The accumulation of heat,' says he, 'near the surface of the earth, which we always experience from continued sunshine, is evidently due to the stoppage of the rays at that surface, and to their multiplied reflexions and refractions, in consequence of which they are as it were absorbed and fixed, for a time, in the soil and in the incumbent atmosphere. By this process the earth, when in a cold state in the end of winter, becomes gradually heated to a certain depth as the warm season advances. On the other hand, when the sun declines, in autumn, the soil thus heated acts as a warm body on the atmosphere, and gives out again the heat it has received.' Howard on the Climate of London, vol. ii. pp. 131, 132. 'Were it not for this effect on the part of the earth,' Mr. Howard continues, 'the heat indicated by the thermometer would probably, on a long average (to obviate the remaining irregularities caused by clouds, rain, wind, and evaporation), be precisely at its maximum and minimum at the solstices, and at the mean at the equinoxes. For the power of the sun is proportionate to the quantity of parallel rays falling on a given area of the earth's surface. And this quantity is greatest when they are vertical, and diminishes as they become more oblique; till in a perfectly horizontal position of the rays it is null.'

It results from these causes, that the maximum and minimum temperatures of our climate, in place of coinciding with the solstices, are removed to a whole month after them; and, in like manner, the mean temperature of the year is developed about a month after either equinox. In consequence of this fact, which is fairly deduced from actual observation, Mr. Howard is led to propose a new division of the seasons, more consonant with the actual phenomena on the earth's surface amid which we live, than the present, which has regard only to the remote causes of temperature, and not to the actual temperature which exists around us. This natural division is effected by 'removing the beginning of the seasons fifteen days from their respective present situations, and placing them at that distance before the equinoxes and solstices.

'By this arrangement, Spring would begin the 6th of March, at the temperature (for London) of 39·94°, would occupy ninety-three days, and end on the 6th of June, at the temperature of 58·08°—the temperature having risen 18·14°. Summer on the 7th of June, and last ninety-three days; during which space the mean temperature (of London) will have risen from 58·08° to 64·75°, or 6·67°, and have declined again 6·59°. Autumn, on the 8th of September, at 58·16°, and have ninety days; during which the mean temperature will have declined 18·35°. Winter, comprehending eighty-nine days (or in leap-years ninety), would begin 7th of December.—During this season the mean diurnal temperature having fallen 5·36 (viz. to 34·45°), would have again risen 5·49°, or to 39·94°, on the 5th of March, the concluding day of the season.'—Vol. ii. p. 130.

We must here notice the singular fact established by Mr. Howard, from comparing his own observations at Plaistow, Stratford, and Tottenham Green, with those recorded in the Philosophical Transactions for thirty years, and which were made at the Royal Society's apartments in London, that the temperature of the air in this metropolis is regularly raised by artificial sources of heat to 2° on the annual mean above that of the immediate vicinity.

Mr. Howard's explanation of this singular difference is the following: 'That the superior temperature of the bodies of men and animals is capable of elevating, in a small proportion, the mean heat of a city or populous tract of country in a temperate latitude, is a proposition which will scarcely be disputed. Whoever has passed his hand over the surface of a glass hive, whether in summer or winter, will have perceived how much the little bodies of the collected multitude of bees are capable of heating the place that contains them. But the proportion of warmth which is induced in a city by the population, must be far less considerable than that which emanates from fires, the greater part of which are kept up for the very purpose of preventing the sensation attending the escape of heat from our bodies. A temperature equal to that of spring is hence maintained, in the depth of winter, in the included part of the atmosphere, which, as it escapes from the houses, is constantly renewed: another and more considerable portion of heated air is constantly poured into the common mass from the chimneys; to which, lastly, we have to add the heat diffused in all directions from the foundries, breweries, steam-engines, and other manufacturing and culinary fires.' Vol. ii. p. 104. To these direct additions of extraneous heat, Mr. Howard also adds the augmentation derived in summer, from the accumulation of the natural temperature by the artificial condition of the city.

The excess of the city temperature is least in spring and greatest in winter, and seems to belong entirely 'to the nights, which average 3°$\frac{7}{10}$ warmer than the country, while the heat of the days, owing without doubt,' as he says, 'to the interception of a portion of the solar rays by a constant veil of smoke, falls, in a mean of years, about a third of a degree short of that in the open plain.' The following is the proportional superiority of the London temperature in the twelve different months.

| | |
|---|---|
| January . | $\frac{1}{17}$ |
| February . | $\frac{1}{24}$ |
| March . | |
| April . | |
| May . | $\frac{1}{114}$ |
| June . | $\frac{1}{48}$ |
| July . | $\frac{1}{62}$ |
| August . | $\frac{1}{49}$ |
| September | $\frac{1}{36}$ |
| October . | $\frac{1}{26}$ |
| November | $\frac{1}{20}$ |
| December | |

The mean temperature of London, according to Mr. Howard, is 48° 30′ of Fahrenheit, or about 2° less than has usually been supposed. This varies, he says, in different years as much as 4° 30′, and the variations, he very singularly contends, are periodical, and appear to recur in

cycles of seventeen years. We cannot afford space for the detail of the circumstances which led him to form this opinion; but extract from the summary of the work an abridged enunciation of the fact:—

'We may consider one of these cycles as commencing either with 1790 or 1800, and ending with 1806 or 1816. In either case, a year of mean temperature begins the cycle, in which the coldest year falls at the end of ten years, and the warmest at the end of seven years, reckoning from the coldest, and thus alternately; both together including a complete revolution of mean temperature from its highest to its lowest extreme (or vice versa from the lower to the higher), and back again. The year 1816, which was the coldest of a cycle, appears to have had parallels in 1799 and 1782; and there is every reason to conclude, from present appearances, that the warm temperature of 1806 will re-appear in 1823, which will probably be the warmest, and 1833 the coldest, upon the whole year, of a cycle of seventeen years, beginning with 1807.' Vol. ii. p. 289. The greatest heat to which the climate of London is liable is 96°, the greatest cold is —5°: thus the full range of the thermometer is not less than 100°.

A temperature above 80° is almost always followed, either in our own or the neighbouring districts, by thunder-storms, which, in their turn, are succeeded by rain and a reduction of heat. Owing to our insular situation, and other causes, 'even in the coldest season of the year, the medium of the twenty-four hours, upon a long average, does not fall below the freezing point. Continued frost, in winter, is therefore, always an exception to the general rule of the climate.' p. 292. The following is the mean temperature of the different months, in whole numbers, in the vicinity of London: January 34°, February 39°, March 41°, April 46°, May 55°, June 58°, July 62°, August 61°, September 56°, October 50°, November 40°, December 37°. —The mean annual range is 72°. The mean diurnal range, or difference between the day and night is 14°; and this varies in the different months as follows, beginning with January, 8°, 10°, 12°, 15°, 17°, 18°, 17°, 17°, 16°, 13°, 10°, 8°.

Before we dismiss these comparative estimates of the temperature of our climate, we may compare from the respective works of Dr. Forbes, on the climate of Penzance, and Mr. Howard's Treatise, the mean temperature of the year in London and Penzance. Both works rank with our most accurate and faithful histories of the weather.

I.—*Mean Temperature.*

| | Jan. | Feb. | Mar. | April | May. | June. | July. | Aug. | Sep. | Oct. | Nov. | Dec. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| London . . . | 34 | 39 | 41 | 46 | 55 | 58 | 62 | 61 | 56 | 50 | 40 | 37 |
| Penzance . . | 41 | 44 | 44 | 49 | 56 | 60 | 62 | 61 | 58 | 53 | 46 | 43 |

II.—*Extreme Temperature.*

| | | Jan. | Feb. | Mar. | April | May. | June. | July. | Aug | Sep. | Oct. | Nov. | Dec. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| London | Max. | 56 | 57 | 73 | 80 | 87 | 88 | 96 | 83 | 85 | 73 | 62 | 56 |
| | Min. | 8 | 11 | 18 | 22 | 29 | 36 | 39 | 37 | 26 | 24 | 17 | 14 |
| Penzance | Max. | 56 | 58 | 62 | 68 | 74 | 78 | 78 | 78 | 74 | 68 | 69 | 58 |
| | Min. | 19 | 26 | 28 | 32 | 42 | 45 | 52 | 50 | 42 | 37 | 28 | 22 |

It appears, from documents contained in Dr. Forbes's Essay, that the temperature of Penzance retains the same proportional superiority in the colder months over all the places usually esteemed the mildest in our island; for instance, the sea-coast of Devonshire, the Isle of Wight, Clifton, &c.; a fact which well accounts for, and justifies, the resort of consumptive invalids to the western extremity of Cornwall.

In thirteen years the thermometer, at 7 A. M. at Penzance, has only been thirty-seven times below the freezing point; consequently frost is stated to be of rare occurrence; and the exercise of skating entirely unknown among the young men of the place. The average number of days in the year on which snow falls is very little more than two and a half; and, out of the fourteen years, four are recorded on which no snow fell. As the most unequivocal proofs of the peculiar mildness of the winters, Dr. Forbes, at the end of his paper, gives lists of exotic and indigenous plants growing in the vicinity of Penzance; among which are several which we are not accustomed to see out of the green house. In the open grounds two crops of potatoes are often produced in the year. But the most striking feature of the climate in this district seems to be its equability.

During the prevalence of north and north-east winds, the barometer is generally highest in England, and lowest when it blows from the opposite points. Its highest range is from May to August: and the following are the extreme and mean results of seven different places.

| | | Derby. | Dover. | Keswick. | Liverpool. | Middlewich. | Sidmouth. | York. |
|---|---|---|---|---|---|---|---|---|
| Greatest | height | 30·48 | 30·95 | 30·28 | 30·95 | 31 | 30·61 | 30·75 |
| Mean | height | 29·74 | 29·9 | 29·55 | 29·74 | 29.5 | 29·93 | 29·7 |
| Least | height | 28·34 | 28·48 | 28·33 | 28·6 | 28 | 28·81 | 28·6 |

In estimating the mean height of the barometer in London and the neighbourhood, Mr. Howard takes the result of twenty years at Somerset House, viz. 29·823 inches; and that of his own ten years observation. The mean of the greatest elevations of the mercury in each month for the ten years, is 30·305; and of the greatest depressions 29·188. The mean of the maxima of each year is 30·555, and of the minima 28·557. The mean annual range is therefore 1·998 inches. The extreme range in the ten years is 2·49. The greatest elevation in the ten years occurred on the 24th of February, 1808, viz. 30·71; and the greatest depression on the 29th of January, 1814, viz. 28·22. The former condition took place during a moderate north-east wind, and the latter during strong southerly gales.

Mr. Howard has established another curious fact in his researches: viz. the decided influence of the moon on the barometer. By comparing the results of that instrument at the different phases, for a period of ten years, he found that the mercury 'suffers a depression of about a tenth of an inch, by the influence of the new and full moon respectively; while, at the first and third quarters, the moon's influence is, in respect of position in her orbit, neutral, producing neither elevation nor depression in the barometer.' p. 226. And, by comparing the barometric indications during different periods of the moon's declination, he ascertained that the quicksilver stands considerably above the mean, while the moon is south of the equator, and, in a like proportion, below it, while she is to the north of the equator. On further examining the temperature, winds, rain, &c., in the different periods answering to these varied affections of the moon's path, he ascertained, as might indeed have been expected, that these suffered corresponding, but certainly less uniform, changes.

Our *winds* blow with the greatest constancy, as well as strength, from the west and south-west, as is evinced by the leaning of the trees, in all parts exposed to its influence, towards the opposite quarters. This is thought to arise from the situation of the island with respect to the Atlantic and the Continent, and the difference of atmospheric temperature between them at certain seasons of the year. Next to these, the east and north-east winds are the most prevalent. It generally blows least from the south and north-west. So great is the inconstancy, however, that in summer it often blows from several points of the compass in the same day. In the maritime parts of England, especially in the south, during warm and settled weather, the sea-breeze prevails in the middle of the day, and the land-breeze, morning and evening. In the neighbourhood of London Mr. Howard's observations are, 1. A wind from the north or between that and the east prevails on an average seventy-four out of the 365 days of the year; the extremes being ninety-six and fifty-eight days. 2. A wind from east to west prevails fifty-four days, varying in different years from seventy-two to thirty-four days. 3. A wind from south to west 104 days, varying from 123 to seventy-eight. 4. A wind from west to north 100 days, varying from 124 to eighty-three. 5. Variable winds obtain about thirty-three days, or the remainder of the year, being for the extremes of fifty-one to seventeen days.

Mr. Howard has a valuable observation on the 'apparent anomaly of a north-west wind, predominating in our wettest season in summer, and a south-west during the autumnal rains.' 'I conclude,' he says, 'from a careful review of the cases, that the former is not the carrier but the condenser of the vapor, which appears to be introduced, at intervals only, from the south and south-east. When the surplus vapor has been disposed of in rain on these occasions, the north-west resumes its sway, the atmosphere recovers its transparency,—' et... ro cernes silvas Aquilone moveri,' Virg. b... is usually not long before the returning clouds indicate the near approach of a new supply of vapor.'

'In the decline of the year, the rain appears to originate in a somewhat different way. The great body of the atmosphere is then usually moving with some force from south-west to north-east, while the sun is declining to the southward. The air already turbid from beginning precipitation, is further charged below by an excess of evaporation from the agitation of much watery surface over which it passes. Every calm interval then affords its shower, followed by wind and evaporation again: and a succession of gales by night, and cloudy days, characterise the approach to the hibernal season.' —Vol. ii. p. 211.

Mr. Dalton estimates the average quantity of *rain* that falls throughout England at 31·3 inches: at Ware it has been averaged during five years at 23·6 inches. Mr. Howard gives it in London and the neighbourhood at somewhat above 25·0 inches. But the Royal Society during eleven years at only 21·25 inches. The quantity is distributed, throughout the year, according to Mr Howard, in the following proportions:

| | Inches. |
|---|---|
| January | 1·95 |
| February | 1·48 |
| March | 1·29 |
| April | 1·69 |
| May | 1·82 |
| June | 1·92 |
| July | 2·63 |
| August | 2·12 |
| September | 1·92 |
| October | 2·52 |
| November | 2·99 |
| December | 2·42 |

The following years have been the wettest of a series of twenty-three years, and in the order in which they are put down, viz. 1816, 1797, 1807, 1802; and it further appears that 'the warm years were uniformly dry, or below the average in rain, and the cold years uniformly wet, or above the average.' The proportion of rain by day and night is very different, being no less than one-third more in the latter period,—a fact which has been verified in different parts of the kingdom, and which is, doubtless, a beneficent arrangement of that same Providence, which has appointed the day for labor, and the night for rest. The greatest quantity of rain col-

lected in one diurnal space was 2·05 inches, on 26th of June, 1816. The average number of days on which any rain falls is 148,—an immense proportion, and strikingly exhibiting the wetness of our climate.

In considering the comparative humidity of different months and seasons, Mr. Howard confirms the popular adage of 'forty days' rain after St. Swithin' (15th of July), and comes to the conclusion, that although the notion will be found fallacious, if put to the test of experience at any one station in our island; yet that, 'in a majority of our summers, a showery period, which, with some latitude as to time and local circumstances, may be admitted to constitute daily rain for forty days, has come on about the time indicated by this tradition.' The fact itself is accounted for by the proximity of the summer solstice; as the second rainy period of the year is accounted for by the proximity of the winter solstice. In respect of the influence of particular winds in causing rain, Mr. Howard shows, by calculation, what was before generally known by common observation, that north-east winds are our dry-weather winds, and south-east our wet. The winds from west to north are, also, more or less connected with our fair weather, while those between the south and west have no decided connexion with either wet or dry weather. These remarks, however, are intended to apply only to London and its vicinity, or, at most, to the central parts of the island: the influence of the particular winds in the south-western extremity of Great Britain is very different. It may be further observed, after this author, that in the three dry years, 1807, 1808, and 1815, the proportion of north-easterly to south-easterly winds was nearly double, being 211 of the former, to 108 of the latter: while, in the wet years, 1810, 1812, 1814, and 1816, the proportion of the former to the latter was only as 323 to 269. In the wettest year of the series (1816) the south-easterly winds actually exceeded those from the north and east.

In an estimate of the moisture of this climate we must not omit to notice the *dew*, which Mr. Dalton estimates at an average annual depth of about six inches. The evaporation of South Britain he estimates at twenty-three inches.

The *soil* of the southern parts of Great Britain is extremely various. The downs of Sussex and the west, like the wolds of Yorkshire, are calcareous. Somersetshire, Devonshire, and Cornwall, contain a boundless variety of downs, rocks, marshes, heaths, and vales, intermixed in almost every direction; the most luxuriant slopes being not unfrequently crowned by the most barren summits. The soil of the midland counties is more uniform, being generally a strong loam, though sandy soils cover a large space in Nottinghamshire, and calcareous earth abounds in many parts of Northampton. That species of ferruginous soil called red land by the farmers, is also found in these districts. Staffordshire and Derbyshire have large tracts of peat or moss; but Norfolk is almost entirely a sandy loam, except in the eastern part, where clay appears. In the wealds of Kent, Sussex, and Surrey is the greatest surface of unbroken clay land. Clay also abounds with other strong soils in the north: the highest ranges are of course rocky, and abound with peat; lower down is a lighter loam.

The woodland counties are Kent, Surrey, Sussex, Hampshire, Worcestershire, and Cheshire, with parts of Oxfordshire, Berkshire, Leicestershire, and Northamptonshire, to which may be added, a portion of Yorkshire. The western side of the island is, in general, better wooded than the eastern. The timber of England and Wales has been estimated as equal in value to two years' rent of the land. It consists principally of the noble oak, the ash, elm, lime, beech, chestnut, sycamore, maple, birch, alder, abele, hornbeam, aspin, and poplar.

The entire quantity of land in England and Wales has been estimated at 37,334,000 acres: giving for England 32,134,000, and for Wales 5,200,000. The uncultivated portions (including towns, villages, roads, and waters) at 6,714,000 acres, leaving nearly 31,000,000 of acres, covered with profitable timber, or devoted to agricultural improvement. The Board of Agriculture states that 12,000,000 of acres are employed in pasturage, and 4,000,000 for the dairy. About 40,000 acres are occupied as hop-grounds and nurseries; and 50,000 as pleasure-grounds, and fruit and kitchen-gardens. The land in an actual state of tillage has also been estimated at 12,000,000 of acres; of which about 3,200,000 are sown with wheat. Mr. Arthur Young, however, estimates this last quantity at 3,399,326 acres: Dr. Colquhoun states the property annually created in Great Britain and Ireland, by agriculture, at £216,817,624. Mr. Middleton, in his Agricultural Survey of Middlesex, takes the whole value of this produce in England and Wales, in 1800, at £126,690,000. The number of farms has been taken at 2,000,000. The rental of land appears to be about £28,000,000 sterling, and the amount of tithes £2,193,994.

Mr. Comber, in his work on National Subsistence, gives the following computation of the land under cultivation in England and Wales; and its mode of being cultivated. It will be found to differ little from that we have adopted:

| | Acres. |
|---|---|
| Wheat | 3,300,000 |
| Barley and rye | 1,000,000 |
| Oats and beans | 3,000,000 |
| Clover, rye, grass, &c. | 1,200,000 |
| Roots and cabbage cultivated by the plough | 1,200,000 |
| Fallow | 2,300,000 |
| Hop-grounds | 34,000 |
| Nursery-grounds | 9,000 |
| Fruit and kitchen-gardens | 41,000 |
| Pleasure-grounds | 16,000 |
| Land depastured by cattle | 17,000,000 |
| Hedgerows, copses, and woods | 1,600,000 |
| Ways, water, &c. | 1,300,000 |
| Commons and waste lands | 5,094,000 |
| Total | 37,094,000 |

Grazing, dairy, and arable land divide the occupation of the farmer. In the first the coun-

ties of Leicester, Lincoln, Northampton, parts of Yorkshire and Durham, with Somersetshire, are conspicuous. The dairy counties are Cheshire, Gloucestershire, Shropshire, Wilts, Bucks, Devonshire, Dorsetshire, Essex, Suffolk, Cambridgeshire, Derbyshire, and Yorkshire. The arable farms of greatest extent are found in Northumberland, Durham, Yorkshire, Norfolk, Suffolk, Kent, Surrey, Sussex, Essex, Hertfordshire, Hampshire, Bedfordshire, and Berks.

Wheat, our most important grain, is grown in all the last-mentioned districts, to the extent of 3,200,000 acres, which yield about twenty bushels on an average per acre. The barley counties are Norfolk, Suffolk, Cambridge, Bedfordshire, Leicestershire, Nottingham, and Berkshire, with the upper parts of Herefordshire, Warwickshire, and Shropshire. Oats are grown in the northern and fenny tracts of the eastern and midland counties. Rye, which is not so much cultivated as formerly, is found in the higher and sandy soils of the hilly districts: as are peas. Beans flourish in all the strong lands of the kingdom: and clover, tares, and sainfoin are, like potatoes, every where to be found. The last, however, attain their greatest perfection in Lancashire and Cheshire. Turnips are also considered, in most counties, a general crop, and frequently adopted instead of the naked fallow of the old farmers. Cabbages are in some districts grown as food for cattle. Hemp and flax are also occasionally cultivated. Hops distinguish Kent, Sussex, and Surrey; they are also grown in Essex, Hampshire, Nottinghamshire, Worcestershire, and Herefordshire: but Farnham (Surrey) has long been noted for the best of these precarious crops. Seeds and medicinal plants of various kinds are reared on a large scale in several parts of England; as canary-seed, in the Isle of Thanet; coriander and carraway, in Essex; mustard, in Durham, the Isle of Ely, and Essex; rape, in the counties of York and Lincoln; poppy-seed and saffron, in Essex and Cambridgeshire; madder and woad, in Kent; and chamomile, in Derbyshire. Apples, pears, plums, cherries, peaches, apricots, nectarines, currants, gooseberries, raspberries, and other garden fruits are produced in great plenty throughout the country; but the wet weather, and the changeable nature of our climate generally, are injurious to their perfection. Artichokes, asparagus, cauliflowers, cabbages, coleworts, brocoli, peas, beans, kidney-beans, spinage, beets, lettuce, celery, endive, turnips, carrots, potatoes, mushrooms, leeks, onions, and shallots (though several of them not indigenous), are now, in a manner, naturalised to our soil, and are raised in great plenty in our kitchen-gardens.

The orchards of Worcestershire, Herefordshire, Gloucestershire, Somersetshire, and Devonshire, supply the manufacturers of cyder and perry, or other parts of the country, with fruit. Marshall estimates that the four counties of Worcester, Gloucester, Hereford, and Monmouth, yield annually about 30,000 hogsheads of cyder; 10,000 of which, besides 1000 hogsheads of perry, and 1500 tons of fru[illegible] the produce of the first county alone. The [illegible]t of fruit from that county has amounted to 20[illegible]ons annually.

Kent is distinguished for its cherries and filberts; the latter of which occupy some hundred acres of land near Maidstone.

The increase of the expense of cultivating land in England, in modern times, is a subject of some interest to many of our readers. The Board of Agriculture has thus exhibited the averages of three distinct and distant years, which speak for themselves.

| Average Expense of Cultivating 100 Acres of Land, for the following Years. | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | 1790. | | | 1803. | | | 1813. | | |

First among the valuable animals of England ranks its breed of various descriptions of horses. The whole number kept in Great Britain has been estimated at 1,500,000, and includes every valuable variety of that noble animal. The breeds of cattle in various parts of the kingdom have been also cultivated with the greatest care. The entire number of the live stock of this kind in Great Britain is about 5,500,000. Sheep are also objects of great attention and importance throughout England. The introduction of Merinos, and the astonishing modern extent of our manufactures, have together operated as a powerful stimulus in this branch of grazing. Long-wooled sheep abound on the eastern side, and in the low tracts of the island. The annual produce of their wool has been estimated at 137,000 packs, of 240 lbs. each. Short-wooled sheep are kept on all the upland districts, both of England and Wales. Their wool is fine; and the number of them is taken at nearly 15,000,000. That of the long-wooled sheep at between 4,000,000 and 5,000,000. The annual produce of short wools is supposed to amount to 231,000 packs. If the lambs be added, the total number will amount to 26,000,000, and their wool to more than 400,000 packs.

Animals of inferior consequence are—the patient and degenerated ass, whose numbers are much diminished; the mule; the deer; the goat; the English mastiff and bull-dog; the fox; and the hare. The wild-cat is still found in some of the mountainous and woody parts, as well as the badger, otter, marten, several species of the weasel tribe, the squirrel, mole, dormouse and hedge-hog. No wild animals of an important size remain in any part of the kingdom; and the reptiles and numerous insect tribes are com-

paratively harmless. The English birds of prey are chiefly of the eagle and hawk kinds; but the former are not frequently found: and the bustard, sometimes weighing from twenty to twenty-five pounds, may be considered as the largest of the British birds. The golden-crested wren is the least. The most admired of our songsters is the nightingale; the wheatear is the most delicate bird brought to table. Of wild fowl, the most useful are the goose, duck, teal, and widgeon, vast numbers of which are caught annually in the fens, and supply an extensive article of food. Birds of passage annually visit both North and South Britain; among which are the snipe, woodcock, and several species of plover. Game is plentiful in most counties. Poultry and domestic fowls we need hardly observe are every where seen. Many parts of the coast are well stocked with water-fowl and shell-fish; particularly lobsters, crabs, and oysters. The rivers, lakes, and surrounding seas, abound also with a great variety of other fish. The most common of those in our rivers and inland waters are the salmon, trout, pike, eel, perch, carp, sturgeon, and char. On the southern coast the migratory pilchard, and mackerel (which are only caught near the southern part of the island), abound, while herrings are common to all parts. Other much esteemed fish are the turbot, cod, sole, ling, halibut, plaice, haddock, whiting, smelt, mullet, doree, and bret. The shark is occasionally seen, and the whale visits the northern coast, where also the seal and the sun-fish appear. The fisheries round our coasts, and those of Ireland, including inland fisheries, amount in annual value to about £3,000,000 in England and Wales: in Great Britain, including Ireland, at least £10,000,000. See FISHERIES.

It has been estimated that the private property vested in the *mines* and *minerals* of England and Wales cannot be less in value than £68,000,000 sterling; and that in the whole of Great Britain, including Scotland and Ireland, the value is at least £75,000,000. Iron, copper, lead, tin, salt, alum, coals, stones of various kinds, lime, chalk, slate, &c., are found in vast quantities; and the new discoveries in chemistry have extracted many valuable productions from our minerals and fossils. But the eastern and southern parts of the kingdom are wholly destitute of these treasures. Gold has been discovered in particular spots, but in too small quantities to defray the expense of obtaining it; and silver is only to be met with in conjunction with lead or copper ore. Iron is our staple metal, and coal most abundant. Black-lead is a useful production, almost peculiar, it is said, to this country. Rock-salt is a considerable article of export. Marble, spar, and excellent stone for building, are common; together with fullers-earth and the finest clay.

The valuable article of *coal* abounds most in Northumberland, Cumberland, Durham, and Yorkshire; but Westmoreland is destitute of it entirely. Derbyshire, Staffordshire, Shropshire, Leicestershire, and Warwickshire, contain numerous veins. Gloucestershire, Somersetshire, and Monmouthshire, in the west. possess fossil coal, as also does Bovey Heath, in Devonshire. It also extends into various parts of the principality. In 1792 it was computed that 64,724 men and boys were engaged in raising or conveying coal on the rivers Weare and Tyne; and Dr. Thompson states the length of the Newcastle coal formation, from north to south, at twenty-three miles, and its medium breadth at eight miles; giving a superficial extent of more than 180 square miles, or 557,568,000 square yards. The thickness of all the seams at present worth working, is said to be about ten yards. The whole quantity of coal in this district, therefore, amounts to 5,575,680,000 cubic yards. More than 2,000,000 of chaldrons are annually exported. This, including the waste, the above writer computes at 37,000,000 of cubic yards; and, by dividing the whole quantity in the formation by this, the quotient shows that these mines may be worked at the same rate, for 1500 years, before they will be exhausted. By making the requisite reductions for what has already been worked, and other circumstances affecting the consumption, amounting to one-third of the whole, he concludes, that this formation will supply coal, at the present rate of expenditure, for 1000 years from the present time.

The iron districts are the northern parts of Lancashire, Derbyshire, Gloucestershire, and Shropshire. It is also obtained in Northumberland, Cumberland, and Durham; as well as in Yorkshire, Staffordshire, Worcestershire, Wiltshire, Somersetshire, Devonshire, and Monmouthshire. The iron mines of England and Wales, yield together 200,000 tons of pig-iron. Lead is chiefly obtained in Northumberland, Cumberland, Westmoreland, Durham, Yorkshire, Derbyshire, Somersetshire, and Devonshire. Those of Derbyshire are the most ancient lead-mines in the kingdom, having been worked by the Romans. The present produce annually is about 600 tons. But those near Alston, on the borders of Cumberland and Northumberland, yield double that quantity. Britain has been considered, from a still earlier period, as the depository of tin. This, at present, is exclusively confined to the south-west promontory of the island, which yields about 300 tons annually. The people employed in the various processes by which this metal is obtained, are stated at the number of 10,000; and the yearly value of the produce at £500,000. Copper is found in various parts of the great chain of mountains which extend from Cumberland to Cornwall, and in the Isle of Anglesey. The principal mines are in Derbyshire, Anglesey, Cornwall, and Devonshire. Mr. Grenfell states, that the mines of Cornwall and Devonshire, yield about 80,000 tons of ore annually; affording not above 8000 tons of copper, the worth of which may be estimated at about £1,200,000.

Zinc appears in Derbyshire; alum in Yorkshire; gypsum in Derby and Nottingham; fullers-earth in Surry, Berks, and Bedfordshire; potters-clay in Staffordshire, and at Purbeck, Dorsetshire; superior slate is found in the north of England, and in Cornwall, Devonshire, and Leicestershire.

The principal salt mines of this kingdom are those of Northwich, Cheshire. They were dis-

covered in 1670; but the salt-springs of that county were known to the Romans; the whole annual produce of these mines is about 60,000 tons. The brine-springs in the vicinity of Nampt-wich and Middlewich, in the same county, contain about twenty-five per cent. of the fossil, and yield about 45,000 tons annually of fine white salt. Worcestershire, also, contains some productive springs; those of Droitwich yield 600,000 bushels annually. Salt is also found in a spring at Weston, Staffordshire.

Our quarries of stone, as being wholly found in the hilly districts or on the western side of the kingdom, are of course not available for the ordinary purposes of building at a distance: the produce of them, altogether, compared with that of the mines and iron-works, is not considerable; as appears from the following return of the

Profits of the Quarries, Mines, and Iron-works, in 1810, in the counties where they are principally situated: extracted from the parliamentary papers on the property tax.

| Counties. | Quarries. | Mines, as well of Coal as of Iron, Copper, Tin, and Lead. | | Iron-works. |
|---|---|---|---|---|
| | £ | | £ | £ |
| Cheshire | 877 | Coal and iron | 9,568 | 8,354 |
| Cornwall | 2,147 | Tin and copper | 106,028 | |

| Total | 28,960 | | 483,491 | 222,672 |

Sir Frederick Eden in 1812 supposed £116,000,000 to be the annual amount of British manufactures insurable in Great Britain. These he distributed as follows:—British manufactures for home consumption; namely, woollens £11,000,000; cotton goods £6,000,000; leather £12,000,000; flax £2,000,000; hemp £2,000,000; glass £2,000,000; paper £1,500,000; porcelain and pottery £2,000,000; silk £3,000,000; hardware £6,000,000; beer £10,000,000; spirits £4,000,000; soap £1,500,000; salt £1,000,000; candles £2,000,000; miscellaneous articles £10,000,000; making a total of £76,000,000: to which he adds, of British manufactures for exportation, £40,000,000. The value of foreign merchandise deposited in warehouses, shops, &c., and either paid for or virtually paid by debts owing to this country by foreigners, has been estimated at £33,000,000 in England and Wales; at £40,000,000 in Great Britain and Ireland.

Of these the manufacture of woollens of different kinds is the most ancient, and has been considered the staple fabric of the country. Though introduced as early as the time of the Romans, it dated its pre-eminence from the reign of Edward III., and is, at present, chiefly confined to the southern division of the island. The value of the articles annually produced is about £18,000,000, and the number of persons employed in them about 500,000. The cotton manufacture was introduced about the middle of the seventeenth century, and, at the commencement of the eighteenth, did not employ an eightieth part of its present hands. It is now unrivalled in any other country. Manchester, Preston, Bolton, Blackburn, and Wigan, are now its principal seats in England. The annual value of this manufacture to Great Britain is estimated at £20,000,000; and the number of individuals employed in it at 600,000. The linen manufacture, partly superseded by that of cotton, does not now exceed in annual value £2,000,000, or £2,500,000.

The following is an exhibition of the rise, progress, and present state of the cotton manufacture in Great Britain. From 1770 to 1780 the importation of cotton wool averaged 5,735,575 lbs. per annum; from 1781 to 1790 about 18,000,000 lbs. weight; and from 1791 to 1801 about 32,000,000. And the following is a statement of the quantity imported in each of the twenty-two years 1802—1823, distinguishing the several countries whence imported and the number of bags and bales from each respective country

| Years. | COTTON WOOL IMPORTED FROM United States of America. | Brasils and Portugal. | East Indies. | West Indies, &c. | Total No. of Bags & Bales. | Total in lbs. weight. | Quantity in lbs. weight taken for spinning in each of the Nine Years, 1815—1823. |

| 1821 | 300,100 | 121,050 | 29,700 | 37,250 | 488,100 | 128,573,275 | 128,527,725 |
| 1822 | 330,000 | 143,200 | 19,300 | 40,650 | 533,150 | 139,797,735 | 140,795,375 |
| 1823 | 448,070 | 148,070 | 38,650 | 33,610 | 668,400 | 180,233,795 | 150,325,795 |

The following is an account of the official value of the cotton wool imported; the number of bags and bales, and the official value thereof re-exported; and the official and declared real value of the quantity of cotton yarn and of cotton manufactures exported to all parts of the world, except Ireland, in each of the ten years, 1814—1823.

The official values imply a fixed value assigned by the government in 1694; and may or may not have a relation to the real value of the present time; but they are important and interesting as denoting an increase or decrease of quantity.

| Years. | Official value of raw imported. | EXPORTED. Raw. Bags. | Raw. Value. | Value of Yarn. Official. | Value of Yarn. Real. | Value of Manufactures. Official. | Value of Manufactures. Real. |
|---|---|---|---|---|---|---|---|
| 1814 | 2,030,862 | | 366,270 | 1,119,850 | 2,791,248 | 16,690,366 | 17,393,796 |
| 1815 | 3,335,564 | | 397,664 | 808,853 | 1,674,021 | 21,699,505 | 19,124,061 |
| 1816 | 3,160,075 | 30,000 | 343,768 | 1,380,486 | 2,628,448 | 16,335,124 | 13,072,758 |
| 1817 | 4,161,824 | 22,700 | 721,430 | 1,125,257 | 2,014,181 | 20,357,147 | 14,178,021 |
| 1818 | 5,767,547 | 60,000 | 1,245,781 | 1,296,776 | 2,385,305 | 21,627,936 | 16,643,579 |
| 1819 | 4,871,513 | 65,800 | 1,085,536 | 1,585,753 | 2,516,783 | 16,876,206 | 12,388,833 |
| 1820 | 4,957,057 | 27,500 | 370,610 | 2,022,153 | 2,826,643 | 20,704,600 | 13,843,569 |
| 1821 | 4,347,258 | 51,000 | 1,062,302 | 1,898,695 | 2,307,830 | 21,639,493 | 13,786,958 |
| 1822 | 4,731,252 | 58,700 | 1,279,263 | 2,353,317 | 2,700,437 | 24,566,920 | 14,534,253 |
| 1823 | 6,241,561 | 39,700 | 707,312 | 2,425,419 | 2,625,947 | 24,117,549 | 13,751,415 |

By the first of the above statements it appears that the total quantity of cotton wool imported in the nine years 1814—1823, has amounted to about 1,235,000,000 lbs. weight, and the stock on hand at the close of the year 1814 having been about 24,000,000 lbs., it makes a total quantity of 1,260,000,000 lbs. weight in the nine years to be accounted for: which has been disposed of in the following manner, viz. 1,062,000,000 lbs. weight taken for spinning; 105,000,000 ditto re-exported in a raw state; and 92,000,000 lbs. remaining on hand at the close of the year 1823.

Government used much exertion, in the seventeenth century, to improve and extend the manufacture of silk, which was greatly promoted by the settlement of the French refugees in London, Canterbury, &c. Spitalfields is, to this day, the principal place where silk weaving constitutes the employment of the population: it occupies about 30,000 people in that district of the metropolis. Coventry, Derby, Leek, and Macclesfield, also participate in this manufacture. The value of the whole produce has been stated at £4,200,000; and the persons employed, comprising a great number of women and children, is about 70,000.

The manufacture of stockings, chiefly confined to the counties of Nottingham, Leicester, and Derby, is most extensive in the first two counties. It has been computed that more than 20,000 persons in Leicestershire are employed in producing hosiery to the value of £1,500,000 annually. The goods made in Nottinghamshire are chiefly silk and cotton.

But our hardware is the most celebrated of our existing manufactures: 95,000 tons of iron, worth in the raw state £5,000,000 sterling, are supposed to be annually devoted to this object; and the men employed in working this metal to amount, at least, to 200,000. The seats of the great hardware manufactories are at Birmingham, Sheffield, and London (see CUTLERY), where, exclusively, much of the finer and more valuable work is performed. At Birmingham, and the contiguous district of about fifteen miles each way, it is estimated that 100,000 persons are engaged in the larger works. The brass foundry, which is principally confined to that town, is supposed to employ nearly 10,000 people; the button trade from 7000 to 10,000; brace-making 1000; the jewellery and gilding business, from 6000 to 7000; and the burnishing line nearly 20,000! The aggregate annual value of Birmingham articles has been stated at £2,000,000.

Sheffield and its neighbourhood are distinguished for the making of steel, and the manufacture of cutlery and files; as well as for plated goods. The whole are supposed to occupy about 30,000 of its inhabitants, and to be worth, annually, £1,200,000. The entire annual value of articles made of iron in England and Wales is taken at £10,000,000 sterling; and the number of people employed, at 200,000: brass and copper articles at £3,000,000, and the people employed on them, 50,000: steel, plated, and hardware goods, and toys at £4,000,000, and the people employed at 70,000.

This view of the importance of our hardware manufacture will be confirmed by adverting to the following statement from returns made to the house of commons of its value annually, as an export during the years 1830—1.

METALS AND HARDWARE EXPORTED FROM BRITAIN, DURING THE YEARS FOLLOWING.

Clocks and watches, with various jewellery articles, and cut glass, are manufactured to great perfection in the metropolis; where also all the best astronomical, optical, and other scientific instruments are exclusively made. Here alone also is the beating out of gold leaf engaged in. The plate glass and mirrors of England now rival any in the world: the value of this manufacture is estimated at £1,000,000, and the people engaged in it at 40,000.

Tanneries are of frequent occurrence in England: one of the most extensive in the metropolis engages also in the manufacture of Morocco leather, importing its superior goat skins direct from Mogador. The value of the various leather articles, annually made, such as shoes, gloves, harness, saddlery, &c., has been estimated at nearly £10,000,000.

The manufacture of earthenware and porcelain has greatly improved in this country of late. The best clay used in Staffordshire and Worcestershire, the seat of these manufactures, is brought from the Isle of Purbeck, and the coasts of Dorset and Devon. Thousands of tons of flint are also sent hither from the chalk-pits of Kent, and other materials from Cornwall. The principal places in the pottery district of Staffordshire, are Burslem and Etruria, the latter the property of Mr. Wedgewood, to whose family the Staffordshire potteries are much indebted. The annual value of this manufacture is £2,000,000; the persons employed in it about 40,000. Nearly 40,000 tons of shipping are employed in conveying the materials for it to Liverpool, and about 30,000 in exporting or conveying coastwise the finished articles. Superior porcelain is also made at Worcester, Derby, Colebrook-dale, in Shropshire, and Swansea.

Paper, which was once largely imported, is now a valuable export, and principally manu-

factured within a circle of eighty miles from the metropolis. It is supposed to amount, as a manufacture, to the annual value of £1,000,000. Manufactures of a more restricted nature, or inferior extent, we can hardly be expected to particularise. That of gunpowder, however, is worthy of notice, as also that the government certainly excels private manufacturers in making this article; distilleries, sugar-refineries, soap-houses, vitriol, copperas, and white lead manufactories; salt-works, roperies, breweries, hat-manufacturers, &c. &c., are other occupations of the English manufacturing population, which are important to the comfort of every class of society. In the construction of carriages (see our article COACH-MAKING) we have also arrived at distinguished success, and export this elegant manufacture largely.

The following table exhibits the progressive increase of production in some important articles which we cannot more particularly enumerate.

STATEMENT of the thousa[illegible] of BRICKS and TILES; pounds weight of TALLOW and SPERMACETI CANDLES; and of HARD [illegible] SOFT SOAP, and STARCH, charged with Excise Duty in each of the Years 1782—1823. 183[illegible]

The following Statement, extracted from the Custom-House Report, also ordered to be printed by the House of Commons, on the 2d of April, 1819, shows the amount of the shipping belonging to the British empire, with the exception of SCOTLAND and IRELAND (for which see those articles) with their tonnage, and the number of men and boys usually employed in navigating them. On the 30th of September of the three following years, these were,

Vessels employed in foreign trade.—In the year 1831 there were entered inwards in the Ports of the United Kingdom 14,488 British ships (2,367,322 tons, employing 131,627 men, and 6085 Foreign vessels (874,605 tons), employing 47,453 men; and there cleared out in the same period 13,791 British ships (2,300,731 tons), employing 132,004 men, and 5927 Foreign ships (896,051 tons, employing 47,009 men.

The *government* of England is that of her universal and vast empire:—a mixed monarchy, consisting of the KING, who has the prerogative of convening, proroguing, and dissolving parliament; creating peers; assenting to, or rejecting, all bills that pass the houses of lords and commons; appointing every member of the magistracy and executive government, together with the bishops of the established church; and who has the supreme command of the army and navy: the house of PEERS, consisting of the lords spiritual and temporal, the English temporal peers having an hereditary right to sit in the house (but an election being made of Scottish and Irish peers), and their number, therefore, being limited by no existing law: and the house of COMMONS, elected by the people under the four denominations of knights, citizens, burgesses, and barons. The English peers amount to about 400; and the members of the house of commons for England, to 471; but while we now write (April 1832) a bill has passed through the Commons and been read a first time in the House of Lords which diminishes the amount See ELECTION.

The house of commons is distinguished from that of the peers by the right of originating or levying the taxes, and the election of its own members, who are the constitutional guardians of the public purse; and who, therefore, never suffer the lords to make any alteration in money bills.

Bills, which have passed both houses (for they are so denominated throughout their several stages in each), receive the royal assent, and become *Acts of Parliament*, constituting the statute law of the land. Bills of a general description may originate in either house, and are transmitted to the other for discussion, where they may either be altered or entirely rejected. When altered, the amendments must be communicated to the house in which the bill originated, for approbation; and having passed both houses, no further alteration can take place. The royal assent must be then given to it in the state in which it is presented, or withheld altogether. See ASSENT. An act of parliament thus made is 'of the highest earthly authority which this kingdom acknowledges. It has power to bind every subject in the King's dominions, and even the king himself, if particularly named therein. It cannot be altered, amended, dispensed with, suspended, or repealed, but by the same forms, and by the same authority of parliament which gave it existence.' For more minute particulars of the privileges and duties of PARLIAMENT, see that article; for those of the Courts of Law, see COURT and LAW.

The king, by his judges, is not only supposed to be present in all the courts when they assemble; but for the more perfect conservation of the public peace, he is represented at all times, constitutionally, by his *sheriff* of each county. 'As the keeper of the king's peace,' says Mr. Justice Blackstone, 'the sheriff is the first man in the county, and superior in rank to any nobleman

therein, during his office. He may apprehend, and commit to prison, all persons who break the peace, or attempt to break it, and may bind any one in a recognizance to keep the king's peace. He may, and is bound ex-officio, to pursue and take all traitors, murderers, felons, and other misdoers, and commit them to gaol for safe custody. He is also to defend his county against any of the king's enemies, when they come into the land; and for this purpose, as well as for keeping the peace and pursuing felons, he may command all the people of his county to attend him, which is called the posse comitatus, or power of the county; which summons every person above fifteen years of age, and under the degree of a peer, is bound to attend upon warning, on pain of fine and imprisonment. Yet he cannot exercise the office of a justice of the peace, for then this inconvenience would arise, that he should command himself to execute his own precepts.'—1 *Commentaries*, 3[illegible].

Juries, justices of the peace, of which several are put in commission for each county, the coroner, and the constable, complete the general outline of our legal authorities. The duty of the justice of the peace is very general and constant; he is to put the greater part of the statute law in execution, to take charge of highways, the poor, vagrants, treason, felonies, riots, the preservation of game, &c.; and examine and commit to prison all who disturb the peace, or disquiet the king's subjects, removing them to the county gaol for trial at the sessions, held quarterly before the united justices of the county, or at the next county assizes, for trial before the judge of assize, according to the offence. See CORONER and CONSTABLE.

The trial by jury is considered one of the most decided features of the triumph of liberty and intelligence in the executive branch of our constitution. Twelve respectable men of the county, or neighbourhood, where a crime is committed, and who are best qualified for the office, are constituted the judges both of the law in its application, and of the entire facts of every criminal case. When a man is charged with any capital offence, and committed to the county gaol by the magistrates of the district, the charge must first be examined by the GRAND JURY, whose province it is to ascertain if there be sufficient grounds for exposing the person accused to a public trial; for, in the eye of the law, he is considered innocent till it be fully proved to the contrary. Unless a bill of indictment therefore be found against the prisoner, by a majority of this jury, he is immediately discharged, and can never be again indicted for the same offence.

In proceeding to a trial, the person accused is furnished with a list of the PETTY JURY, as it is called, who are to be his final judges, and is allowed in open court to object to any against whom he can assign reasons for their not being admitted, until twelve unexceptionable men are found; and, in order to secure all possible impartiality in the trial, if the person indicted be a foreigner, half the jury are also to be foreigners, if the accused person so desire. They are then sworn that they shall well and truly try, and deliverance make between the king and the prisoner whom they shall have in charge, according to the evidence. On these juries the prisoner rests his cause, and the verdict they pronounce is final. After they have heard the evidence, the prisoner's defence, the comments of the judge on the testimony given, his exposition of the nature of the crime, and the bearings of the law upon it, under every possible aspect, they are confined, without meat, drink, or candle, till the whole are unanimous in acquitting or condemning the prisoner. Trial by jury, as thus constituted, is evidently one of the greatest bulwarks of our freedom. It remains only to be completed by the allowance of counsel to a prisoner in every case. If one of the jury die, while they are locked up, the prisoner is acquitted. This institution has been selected for imitation by all the modern states who have asserted their liberty.

The greatest crime known to the English law is *high treason*, and it is accordingly punished with peculiar severity. The several offences which come under that denomination were limited, by the statute 25th Edw. III., t[illegible] distinct branches, of which, the compassing and imagining the king's death, and the conspiring to levy war against his authority, were the principal. Other treasons have since been added, relating to papists, falsifying the coin, or other royal signatures, and for the security of the protestant succession in the house of Hanover. Two new treasons were created during the late reign (36 Geo. III. ch. 7), viz. that of compassing and imagining to depose the king, and conspiring to levy war to force the crown to change its measures and its councils. The sentence of the law against this offence is, that the offender shall be hanged, drawn, and quartered; and forfeit his lands and goods to the king. The humanity of modern times, however, has dispensed with the literal application of this punishment. Persons convicted of high treason are first hung till they are dead, they are then taken down and decapitated, and the drawing and quartering are wholly disused.

*Petty treason* is when a wife murders her husband, a servant his master or mistress, an ecclesiastic a prelate, or one to whom he owes obedience, the punishment for which is, to be drawn on a sledge to the gallows and hange[d]. Felony includes murder, robbery, forging, maiming, or stabbing with a sharp instrument, &c.; for all which the law awards the sentence of death; a circumstance to which much attention has been of late excited. Some amelioration of these severe enactments are already accomplished; others are said to be intended by the executive. See LAW. Murderers are executed within forty-eight hours from the passing of the sentence, and their bodies dissected. The sentence for robbery, unless attended with circumstances of brutality, is frequently commuted for either transportation, or imprisonment on board the hulks. Fines, imprisonment with hard labor, pillory, and whipping, are the chief punishments assigned by the law for minor offences.

We are indebted to Mr. Capper's Topographical Account of England and Wales for the following

**Statement** exhibiting the counties of **England** and **Wales**, arranged in order of their legal jurisdiction, with the numerical ratio of their total population; the number of divisional meetings or petty sessions, and of acting magistrates in each county.

*** There are 183 cities and towns in England and Wales which have magistrates who lay claim to an exclusive jurisdiction, but most of them exercise only a concurrent jurisdiction with the magistrates of their respective counties, and some of them none at all. All the places holding separate assize are included in the circuits' jurisdictions. The numerical ratio of the total population of the several counties has been inserted for the purpose of more distinctly marking the ratio of crime in comparison therewith, in the respective counties. In the counties where the name of the assize town and county is different, the assize towns are inserted within a (parenthesis): where no notice is taken, the assizes are held at the town of the same name as the county, and in those marked with the following notations the Lent assizes in April are held permanently at the places inserted within the parenthesis; and the Summer assizes in August at the places affixed to their respective counties as follows, viz.—

* For Sussex, at Lewes.
† For Surrey, alternately at Guildford and Croydon.
‡ For Berks, at Abingdon.
§ For Cornwall, at Bodmin.
‖ For Somerset, alternately at Bridgewater and Wells.
¶ For Buckingham, at the town of Buckingham.
** For Norfolk, at the city of Norwich.

The king is the head of the established *church*, which in England and Wales is episcopal; and he has been styled, from the period at which our Henry VIII. assumed this title, his most sacred majesty. His ecclesiastical power is, however, rather external than universal, in the church; at least it is confined in practice to the appointment of the bishops, the disposal of livings, and the regulation of the convocation, or public synod. See Bishop.

The clergy, under the rank of archdeacon (there described), are, rectors, vicars, curates, and deacons; and these constitute the efficient part of the officers of the church. They enjoy the privileges of not being liable to fill any civil or military office; they can only be fined to the amount of their temporal estates; nor are they assessed with the rest of the inhabitants of a parish for the repairs of highways, the expenses of watching, prosecuting for robberies, &c. The whole annual income of the clergy of the church, in South Britain, has been estimated at £3,000,000. No established church has ever been more distinguished for the learn-

ing and ability of its members; or for the liberality with which its great power and political influence have been exercised with regard to other sects.

Dissenters are very numerous in England; but there is no accurate mode of estimating their total numbers. Some of their own body have suggested that one-half of the persons who regularly frequent any place of worship dissent from the establishment. They sometimes act in London in a recognised body of the three denominations of Presbyterians, Independents, and Baptists, whose ministers meet at Red Cross Street library; and are considered in their addresses to the crown, and other communications with the government, as a species of representatives of all the dissenters. But the Presbyterians rank in modern times among the smallest of the dissenting sects. The most numerous is that of the Wesleyan Methodists; next to these perhaps, including England and Wales, the Calvinistic Methodists; then the Independents, perhaps; and then the Baptists, Particular, or Calvinistic, and Arminian or General. The Friends or Quakers are it is well known not very numerous, nor increasing, the Moravians, Swedenborgians, and Unitarians are other small sects, but include many respectable individuals. For their legal situation see the article DISSENTERS.

In the *education* of the country, the established church now takes the precedence due to its station. Committees of the house of commons have also contributed in no small degree to enlighten the public mind upon this topic. The first of their Reports, dated June 1816, contains various statements of the proportion of the poor, who were then destitute of the means of instruction. In the neighbourhood of Covent Garden, the proportion was 679 uneducated out of 829. In Southwark, of 12,000 children between the age of five and fourteen, 6000 were unprovided with the means of instruction; but of all ignorant and abandoned districts, St. Giles's was found beyond comparison the worst; containing more than half the Irish in the metropolis, whose children, in number about 3000, were not only uneducated, but after the age of seven or eight trained to begging and thieving almost universally. The whole number of children in the metropolis, unprovided with education, was computed at more than 100,000, while not less than half a million of the population were equally destitute in the country.

The National Society at the period of the second Report of the committee had established but one great school, that of Baldwin's Gardens, in Gray's Inn Lane: it had contributed to the erection or enlargement of more than 200 schools, by pecuniary grants, varying from £15 to £100, and amounting in particular cases to £200, and even £300. Above 500 teachers, male and female, are trained on Dr. Bell's plan; and distributed over from 1000 to 1500 schools, containing nearly 200,000 children receiving education on this system. The majority of these have adopted Dr. Bell's plan without receiving any other aid than a supply of elementary books; the conditions on which the society furnished them being that the liturgy and catechism of the church of England should be followed, and that no religious tracts, except those sanctioned by the Society for Promoting Christian Knowledge, should be admitted into the schools. The practice of the society, however, is by no means illiberal. In regard to expense, nothing can be more gratifying than to find that, even at the highest, it does not exceed (Evidence, p. 268) 12*s.* per head per annum.

The British and Foreign School Society was found equally active and liberal according to its means, It had expended, on the laudable object of promoting instruction for the poor universally, the sum of £20,000 previously to the year 1816; of which one individual alone (who conceals his name from all parties but the treasurer) subscribed no less than £3000. Its annual expense in training male and female teachers is from £2000 to £3000 a year, and it is connected with from 400 to 500 schools whom it supplies with them throughout the kingdom. About 400,000 children are supposed, according to these reports, to receive instruction by Sunday Schools, in London.

The labors of the education committee were closed with its third Report in June 1818. They here observe that the discussion excited by the enquiry had greatly improved the administration of institutions for the education of the poor; but that much remained to be done; the efforts of private benevolence being almost entirely confined to towns, and the aid of government being wanted in the thinly peopled districts, to the extent, at least, of the purchase or erection of a school-house, leaving the annual expense to be defrayed by private subscriptions. The committee further recommend a connexion between such schools and the established church; observing that the anxiety of the poor for the education of their children, was not only unabated, but daily increasing.

A superior education is to be obtained in England by the public or grammar schools, or at the numerous and very respectable private Academies every where established. The great public schools are Eton, Harrow, Westminster, and Winchester; to which are to be added, in London, St. Paul's, Merchant Taylors' School, and the Charter-House. Here the classics are a prominent object of instruction, and while provision is made by the founders for a certain number of boys to be educated on the *foundation*, youths of the first rank join them, and pay liberally for participating the advantages of these establishments. The Universities of Oxford and Cambridge are entirely restricted to the members of the established church. A new University, designed to embrace all the religious denominations of the country, has been recently completed in the Metropolis. We give a very accurate delineation of the edifice, embracing its complete state, which a want of funds has prevented the proprietors carrying into effect.

The general charities and charitable institutions of England are also numerous and unrivalled. Amongst these, religious and moral institutions seem to claim the pre-eminence. But we cannot undertake to particularize the half of them. The most celebrated are

The Society for Promoting Christian Knowledge.
The British and Foreign Bible Society

The London Missionary Society.
The Church Missionary Society.
The Baptist Missionary Society.
The Wesleyan Missionary Society.
The National Society for the Education of the Poor.
The British and Foreign School Society.
The African Institution.
The Society for Bettering the Condition of the Poor.
The Literary Fund.

Among the principal Hospitals are,

St. Bartholomew's, West Smithfield.
Bethlem, now in St. George's Fields.
St. Luke's, Old Street.
Guy's, Southwark.
The Lock Hospital, Hyde Park-Corner.
The London Hospital, Whitechapel Road.
The Magdalen Hospital, St. George's Road.
The Middlesex Hospital, Berner's Street.
The Foundling.
The Fever Hospital.

The principal Dispensaries of the metropolis.

The General Dispensary, Aldersgate Street.
The City Dispensary.
The Finsbury Dispensary.
Thd Vaccine Institution and Dispensary.

The principal Alms-Houses are,

The Haberdashers'.
The Mercers'.
The Skinners'.
The Ironmongers'.
The East India Company's, &c.

The School Charities.

Christ's Hospital, or the Blue Coat School.
Marine Society.
School for the Indigent Blind.
Deaf and Dumb Asylum.
Debtors' Children.
Ladies' Charity School.
Masonic Charity.
Raines's Charities.

There are also three colleges or alms-houses on an enlarged scale, under a master and incorporated officers, in the neighbourhood of London, viz. Bromley, Morden, and Dulwich Colleges. We can only add, that the example of these numerous and splendid establishments of the metropolis is nobly followed up in the various county and other local hospitals, dispensaries, and public charities of every kind throughout the country. Many of the most flourishing religious institutions are aided materially by the Auxiliary Societies and associations of the provinces.

The army and navy of England at the close of the late war are thus exhibited by Dr. Colquhoun.

| | |
|---|---|
| Land forces, or men in arms in the British Empire, including the Regular Army and Foreign Corps, the British and Irish Militias, the Local Militia and Volunteers of Great Britain; with the Militia and Fencibles in the Colonies and Dependencies . . . . . . . . | 721,187 |
| Brought over . . . . . . . | 721,187 |
| Navy and Marines . . . . . . . | 179,920 |
| Native Army in India, including the India Marine Forces . . . . | 160,913 |
| Total armed Force of the British Empire . | 1,062,020 |

The peace, however, has of course reduced these establishments.

The entire amount of the regular troops, provided for by parliament in 1819, was 91,823, including 11,340 men then added, in consequence of a disturbed state of the country; but exclusive of the regiments employed in the territorial possessions of the East India Company. The whole number of seamen and marines employed at one period of the late war was taken at 184,000 men. They do not now exceed 50,000.

The revenue of Great Britain, whether we regard its past and existing resources, its encumbrances, or its future stability, is a very extensive and momentous topic of consideration. We can only advert briefly to its history and present state.

The average revenue of Great Britain, under king William III. was about £4,000,000. This was a period of difficulties and of a disputed succession, it will be remembered: under queen Anne an augmentation to £5,000,000 took place, and eventually to £6,000,000. During the reign of George I. the revenue rather exceeded £7,000,000, and a gradual increase is to be observed towards the middle of the century. The revenue during the reign of George III. is thus exhibited.

| | |
|---|---|
| 1761 it was | £8,800,000 |
| 1764 . . . | 9,250,000 |
| 1767 . . . | 9,200,000 |

| 1801 . . . | 28,085,829 |
| 1802 . . . | 28,221,183 |

The following is a view of the income of our government from taxes and loans since that period to 1817, and the public expenditure, during the same period. They exhibit the greatest amount of taxation ever sustained by this, or perhaps any other country, and the nature of our expenses at the same time, during unexampled periods of public exertion.

## PUBLIC INCOME OF GREAT BRITAIN IN EACH YEAR, FROM 1803 TO 1817 INCLUSIVE.

These statements form a history of our finances since 1803. The deficiency of revenue in 1817 was met by a large issue of exchequer bills. In 1818 the revenue improved by nearly £2,000,000; but there still remained a deficiency of £13,000,000, which necessitated a recourse in that year to temporary expedients; and, in the year 1819, there were a loan and a vote of additional taxes, to supply this.

We may now compare with the foregoing the following table, extracted from the Financial Accounts, printed and laid on the table of the house of commons, for the year 1832.

Net Public Income and Expenditure of the United Kingdom of Great Britain and Ireland, in the year ending 5th January, 1832.

| Income or Revenue. | Total. | Expenditure. | Total. |
|---|---|---|---|
| ORDINARY REVENUES AND RECEIPTS. | £. | FUNDED DEBT. | £. |

## UNFUNDED DEBT.

The total amount of Exchequer Bills outstanding on the 5th of January, 1832, £27,123,350

'The effect of the *national debt* on the general internal circumstances of the country, and on the intercourse between man and man involved in all the transactions of business,' argues a late writer in the Quarterly Review, 'is not, perhaps, as correctly understood as might have been expected, in a country where a national debt has so long existed. If an individual has a rental of £5000 per annum; and pays, in direct or indirect taxes, £1000 per annum, which he would not pay but for the existence of the national debt, he is, in point of fact, not the possessor of £5000 per annum, but of £4000. If a servant receives twenty pounds wages, and pays, in direct or indirect taxation, twenty per cent., in point of fact his real wages are only sixteen pounds instead of twenty. If this illustration were pursued, it would be found that every person, the payer of direct or indirect taxes, must be so much the poorer in consequence of this national debt; but nevertheless that—admitting, for the sake of argument, that the debt could be so adjusted, that every man should only pay a certain amount, which should be exactly twenty per cent.,—all parties would remain in the same relative positions towards each other, as if no debt existed. Now, let the case be supposed—that, in a country where no taxes exist, a proprietor of land has a rental of £5000 a-year, and a mortgage of £20,000 at five per cent. upon his property—he would be precisely in the same situation as an English landlord, whose real income would be £4000 and not £5000 per annum. The effect, therefore, of the national debt, if it could be duly adjusted, would be to make every member of the community nominally poorer, as to real income, but yet to keep all of them equally rich with respect to each other; and this most important condition must be remembered, that the debt would exclusively fall on those parties who paid taxes, directly or indirectly. If population were not redundant,—if the demand for the services of the laboring classes were proportioned to the supply of labor—those classes would suffer the least from the operation of the national debt, because they would secure themselves by an adequate rate of wages from any burden of the debt, which could fall on them beyond their fair share, as direct or indirect payers of taxes. But when population is redundant, they have no compensating remedy of this sort.

'The main inconvenience arising from the national debt consists in the utter impossibility, with any ingenuity of legislation, of adjusting the different proportions of that debt, which particular classes should in equity contribute, so permanently, as not to admit of occasional dislocations of such contributions; for, of course, when from such dislocation, in itself unavoidable, any one class is called upon to pay more, in point of fact, of the general debt than its own fair share, the distress and injury of all who belong to it must be the result. It is perfectly well known that every human being sustains a weight of air of great magnitude, but that, from the equality of the pressure on every part of his body, he moves about as if the pressure did not exist. The moment, however, that that uniform and balanced pressure is removed from any one part, then it is that the weight of the atmosphere is felt, and, as every person conversant with the elements of natural philosophy knows, would, if suffered long, injure, if not destroy the human frame. This analogy would be applicable at all points to the national debt, if that debt were not in its essence an evil; for if the debt could be adjusted to every person with that mathematical accuracy with which nature has adjusted the pressure of the air, it is not a paradox to say that much of the inconvenience of the debt would cease to be felt. But the main and the essential evil lies behind; it is this: that under a system of national debt, a thousand circumstances require to be directed by legislation, which would find their own level without legislation, but for the existence of this universal mortgage; and nothing is more to be regretted than that the speculative remedies suggested by ingenious men for the annihilation of the debt, by a concurrent sacrifice on the part of all classes of the community, involve measures infinitely more complicated, even than those which are necessary for adjusting the practical inconveniences inseparable from its existence.'

This writer afterwards insists—'For the current expenditure the existing government is responsible—for the establishments, for their necessity, for their efficiency; but for the payment of the interest of the national debt, it has no individual character of responsibility. To provide for that payment is the business of the nation at large. Its amount is not regulated by discretion, which is the case in establishments. It remains, for the most part, one and the same immutable, a fixed quantity, and must remain so until, on the one hand, it be discharged, or, on the other hand, it be diminished;—two alternatives, the one of which, is all but impossible, and the other, it is to be feared, more than improbable, with the exception of the effect of a small real sinking-fund. This mode of presenting for observation the Financial Accounts of the year saddles the government exclusively with an odium to which (as already contended) it has no exclusive claim. The proportionate extent and influence of the national debt, as compared with the current expenditure of government, will be appreciated by any person who will take the trouble of inspecting our scale. If it be necessary that the ministers of the day should be considered as stewards of this great national mortgage—as a kind of committee appointed to communicate on the subject of it to parliament and to the country—why should they not appoint an exclusive day for its consideration, and thereby rid themselves of that unreal responsibility which the present system of confused and blended accounts gratuitously throws upon them? We beg not to be understood as taking any extravagantly dark and gloomy view of the national debt, which we would thus desire to see separated from the current expenditure of the government establishments; on the contrary, we would ask if it be not, after all, a plain truth, that this country, at the present moment (depressed as it may be), is ten times more able to support and maintain its present debt, and its present establishments, than it would have been

able to maintain one-fourth part of that debt and of those establishments in the reign of queen Anne? May not a period arrive, at which this country may be able to sustain a debt twice as great, without one-twentieth part of the inconvenience now endured, collectively and individually? Undoubtedly, no man of fair information and common candor will deny that these questions may be reasonably answered in the affirmative. He may, indeed, doubt as to the existence of any future period when such speculations may be realised. With respect to public debt, the country have learnt a lesson which will not be easily forgotten; they have learnt that, to carry on a war-expenditure much greater than the current supplies of the year, must inevitably entail upon posterity a charge and inconvenience, which ought to make the country more than unwilling to consent to the recurrence of such anticipation of future resources. Occasions may arise in which no sacrifice ought to be considered as too great. Such have arisen heretofore; and mighty sacrifices have purchased good too great to be estimated in pounds, shillings, and pence.

Sic species terris, vitæ sua forma, suusque
Dis honor,—IPSA sibi tandem sic reddita MENS est.'

If national honor and the good of man again require such a sacrifice, undoubtedly it ought again to be made; but if ever it be so made, it will be made with a more accurate appreciation of the consequences than was felt by those whose measures incurred the existing debt, or by the people, who were strictly, and all but unanimously, consentient to the enactment of those measures.

'If a private individual, a country gentleman, for example, has a rental of £6000 per annum, and a rent-charge upon it of £4000 per annum, his expenditure, if he be a prudent man, is necessarily limited to his real surplus, namely £2000; and if he has the reputation of having a rental of £6000, and an acknowledged expenditure of only £2000, supposing that he has no special motives for economy, he sustains the imputation of niggardliness, from the apparent disproportion between his income and expenditure. Precisely the converse effect takes place with respect to the government: the government having an income of £60,000,000 per annum, more than £40,000,000 of which, if duly analysed, will be found to belong to the annual charge of the existing debt, has the reputation of being criminally lavish with respect to its establishments, the expenses of which are blended together, most gratuitously and unfortunately, with the interest of the debt. If the accounts were kept strictly separate, the extent of the expenditure for which the government were really responsible would be found to be less than one-third of the whole; whereas now, the line of distinction between the two is not in the slightest degree preserved.' But we shall return to the subject under the article FUNDS.

The *poor laws* of England are amongst the most serious burdens of the people. In three years, ending 1750, they averaged only £692,000 in England and Wales: in three years, ending 1815, £6,[illegible]47,000. But wheat, it is to be observed, was only 4*s.* 5*d.* per bushel in the former case, and 12*s.* 8*d.* in the latter. It is stated that the number of persons receiving relief is greater by far in this country than it ever has been in any other at any period, being, on a rough calculation, one in every *eleven* of the population.

A report of the committee of the house of commons on the Poor Laws in 1817 exhibits the following detailed returns on this subject both for London and the country.

I.—RETURN of POOR-RATES from London, Westminster, and Southwark, being from the Parishes within the Bills of Mortality, delivered to Parliament 21st of February, 1817.

| | Year Ending | | |
|---|---|---|---|
| | Easter 1813. | Easter 1814. | 25th March 1815. |
| | £ | £ | £ |
| Total raised in the metropolis by poor's rate, and smaller rates, such as church-rate, highway-rate, &c. | 446,542 | 501,952 | 489,321 |
| Charitable donations for parish schools and other purposes | 18,983 | 19,620 | 20,160 |
| *Expenditure.* | | | |
| Relief and maintenance of the poor | 370,518 | 401,954 | 380,281 |
| Lawsuits, removals, expenses of overseers, and other officers | 15,324 | 17,416 | 17,433 |
| Families of militia-men | 12,916 | 10,837 | 6,613 |
| Church-rate, highway-rate, county-rate, &c. | 98,903 | 113,574 | 103,807 |
| Total | 497,661 | 543,781 | 508,134 |
| *Number of Poor relieved permanently.* | | | |
| In workhouses | 13,389 | 13,373 | 12,341 |
| Out of workhouses (without reckoning the children) | 12,654 | 13,762 | 13,341 |
| Parishioners relieved occasionally, either in or out of workhouses | 40,993 | 69,332 | 70,322 |
| | 67,036 | 96,467 | 96,004 |

## II.—*Returns applicable to the Kingdom at large.*

The history of our poor laws is a very interesting and important study. Our law takes notice of the poor, 1st. By impotency and defect; as the aged or decrepid, fatherless, or motherless; poor under sickness, and persons who are idiots, lunatics, lame, blind, &c.; these the overseers of the poor are to provide for. 2dly. Poor by casualty; such as housekeepers, decayed or ruined by unavoidable misfortunes; poor persons overcharged with children; laborers disabled, and these, having ability, are to be set to work; but if not able to work, they are to be relieved with money. 3dly. Poor by prodigality and debauchery, also called thriftless poor; as idle slothful persons, pilferers, vagabonds, strumpets, &c., who are to be sent to the house of correction, and be put to hard labor, to maintain themselves; or work is to be provided for them that they do not perish by want; and if they become impotent by sickness, or if their work will not maintain them, there must be an allowance by the overseers of the poor for their support. There is no man so indigent or wretched, but he may demand a supply sufficient to all the necessities of life, from the more opulent part of the community, by means of the several statutes enacted for relief of the poor. 1 *Black. Comm.* 131.

The poor of England, till the time of Henry VIII., subsisted entirely upon private benevolence and the charity of well-disposed Christians; and the poor in Ireland have, to this day, no relief except from private charity. By an ancient statute, 23 Edw. III., cap. 7, it was enacted, that none should give alms to a beggar able to work. It appears by the Mirror, that at the common law, the poor were to be 'sustained by parsons, rectors of the church, and the parishioners; so that none of them die for default of sustenance.' And by stats. 15 Rich. II., cap. 6; 4 Hen. IV., cap. 12, impropriators were obliged to distribute a yearly sum to the poor parishioners, and to keep hospitality. By stats. 12 Rich. II., cap. 7; 19 Hen. VII., cap. 12, the poor were directed to abide in the cities and towns wherein they were born, or such wherein they had dwelt for three years; which seems to be the first rudiment of parish settlements.

No compulsory method, however, was marked out for the relief of the poor, till the stat. 27 Hen. VIII., cap. 25; under which provision was ordered to be made for the impotent poor. Before that time, the monasteries were their principal resource; and among other bad effects, which attended these institutions, it was not,

perhaps, one of the least, though frequently esteemed quite otherwise, that they supported and fed a very numerous and very idle poor; whose sustenance depended upon what was daily distributed in alms at the gates of the religious houses. But, upon the total dissolution of these, the inconvenience of thus encouraging the poor in habits of indolence and beggary, was quickly felt throughout the kingdom; and abundance of statutes were made in the reign of king Henry VIII. and his children, for providing for the poor and impotent; which, the preambles to some of them recite, had of late years greatly increased. These poor were principally of two sorts; sick and impotent, and therefore unable to work: idle and sturdy, and therefore able, but not willing to exercise any honest employment. To provide, in some measure, for both of these, in and about the metropolis, Edward VI. founded three royal hospitals; Christ's and St. Thomas's, for relief of the impotent, through infancy or sickness; and Bridewell, for the punishment and employment of the vigorous and idle.

But these were far from being sufficient for the care of the poor throughout the kingdom at large; and, therefore, after many other fruitless experiments, by stat. 43 Eliz. cap. 2, overseers of the poor were appointed in every parish, whose office and duty are principally these: first, to raise competent sums for the necessary relief of the poor, impotent, old, blind, and such other being poor, and not able to work, and them only; and, secondly, to provide work for such as are able and cannot otherwise get employment; but this latter part of their duty, which, according to the wise regulations of that salutary statute, should go hand in hand with the other, is now most shamefully neglected. 1 *Black. Comm.* cap. 9, pp. 359. 460.

Mr. Justice Blackstone states, at considerable length, the evils arising from what he considers as a deviation from the original purpose of the poor laws, by accumulating all the poor in one workhouse; a practice which he condemns as destructive of the industry and domestic happiness of the poor. He also reprobates the subdivision of parishes; the plan of confining the poor to their respective districts; and the laws passed since the Restoration; as having given birth to the intricacy of our poor laws, by multiplying and rendering more easy the methods of gaining settlements; and, in consequence, creating an infinity of expensive law-suits between contending neighbourhoods, concerning those settlements and removals. He now proceeds to state the general heads of the law relative to the settlement of the poor; which, he truly observes, by the resolutions of the courts of justice thereon, within a century past, are branched into a great variety. 'And yet,' he concludes, 'notwithstanding the pains that have been taken about these laws, they still remain very imperfect, and inadequate to the purposes they are designed for; a fate that has generally attended most of our statute laws, where they have not the foundation of the common law to build upon. When the shires, the hundreds, and the tithings were kept in the same admirable order in which they were disposed by the great Alfred, there were no persons idle, consequently, none but the impotent that needed relief; and the stat. 43 Eliz. cap. 2, seems entirely founded on the same principle. But when this excellent scheme was neglected and departed from, we cannot but observe, with concern, what miserable shifts and lame expedients have from time to time been adopted, in order to patch up the flaws occasioned by this neglect. There is not a more necessary or certain maxim, in the frame and constitution of society, than that every individual must contribute his share, in order to the well-being of the community; and, surely, they must be very deficient in sound policy, who suffer one-half of a parish to continue idle, dissolute, and unemployed; and at length are amazed to find that the industry of the other half is not able to maintain the whole.' 1 *Black. Comm.* cap. 9.

The average sum applied to the relief of the poor for the years 1748, 1749, 1750, was £690,000 per annum. In 1776 it amounted to £1,531,000, an increase far beyond what the rise in the prices of corn would justify; in 1783, 1784, 1785, to £2,000,000, though the average price of corn had fallen during the nine intermediate years.

In the year 1795 a change took place in the administration of the poor laws, which has completely altered the state of the country. This was a winter of unusual scarcity. The price of corn, per quarter, which for the three preceding years had stood at £2 14*s.*, averaged more than £4 during the whole of 1795 and 1796. As the returns of labor could not be expected to keep pace with such a sudden rise in the necessaries of life, distress was universal; and there appeared as claimants for parochial relief, not only the infirm and aged, but the able-bodied and industrious, who had few of them ever before resorted to the parish, and that only during temporary illness and disability. It was at this season of acknowledged difficulty, that the county magistrates, first in Berkshire, and afterwards in other parrs of the middle and south of England, agreed to relieve the poor according to a fixed and uniform scale, regulated by the price of bread; and issued a table, which professed to show, at one view, what should be the weekly income of the laboring poor, which it fixed in a certain ratio, according to the price of bread and the size of the family. Whatever the man's labor produced less than the provisions of this table required, was made up by the parish, whose compliance was subsequently enforced by the legislature; and the justices were empowered, under certain conditions, to order relief out of the workhouse, and to those who possessed property of their own. 36 Geo. III. cap. 23.

The practical operation of this system has been thus illustrated. Every laborer is presumed to require a gallon loaf of standard wheaten bread, weekly, for every member of his family, and one over; i. e. four loaves for three persons; seven for six. A B has a wife and four children; he claims seven gallon loaves, costing, we will suppose, 12*s.* But his wages are only 9*s.*; therefore the parish supplies him

with 3s. weekly. C D has a wife and six children; he requires nine gallon loaves, or 14s. 8d. He earns 10s.; the parish makes up the rest. E F is so idle and disorderly, that no one will employ him; but he has a wife and five children, and requires eight gallon loaves for their support. His allowance, then, is 9s. in lieu of the wages which he ought to earn, and 5s. or 6s. to make up the deficiency of these wages.

The distress which followed the spring of 1815, the consequent increase of the poor-rates, and the difficulty of meeting them, brought our existing system into full operation, and led to a long and diligent enquiry into the whole subject before a committee of the house of commons, in the session of 1817. From the returns which were then made from the manufacturing towns of Birmingham, Manchester, Coventry, &c.; and also from many districts solely agricultural, it clearly appeared that the excess of demand above the funds prepared to answer it, was not merely a theoretical evil, but one which some districts had already experienced, and to which all were more or less rapidly approaching. In Manchester, according to the report of the committee, the relief given to the out-door poor increased, within ten years from 1805, to £14,000, instead of £8000 per annum; and the whole expenditure, from £16,000 to £27,000, in the most moderate years; in dear seasons, one-third more. In Birmingham the increase in ten years was one-third, being £20,000 in 1806, £30,000 in 1816. Distraint for rates became very general; and every distraint was felt to be a wasteful encroachment upon the national resources.

'Whether the assessment,' said the committee, 'be confined to land and houses, as at present, or other denominations of property be made practically liable to the same charge, the committee feel it their imperious duty to state their opinion, that, unless some efficacious check be interposed, there is every reason to think that the amount of the assessment will continue, as it has done, to increase, till at a period, more or less remote, according to the progress the evil has already made in different places, it shall have absorbed the profits of the property on which the rates may have been assessed; producing thereby the neglect and ruin of the land, and the waste or removal of other property, to the utter subversion of that happy order of society so long upheld in these kingdoms.

'The gradual increase which has taken place both in the number of paupers, and in the assessment for their support, can hardly fail to have arisen from causes inherent in the system itself; as it does not appear to have depended entirely upon any temporary or local circumstances. Scarcity of provisions, and a diminished demand for particular manufactures, have occasioned, from time to time, an increased pressure in particular parishes.' But, by comparing the assessments in the two counties in this kingdom, in which the largest portion of the population is employed in agriculture, namely, Bedfordshire and Herefordshire, it will be seen that there has been the same progressive augmentation in the amount of the assessments, as may be observed to have taken place in the manufacturing counties.'

| | Money Expended on Paupers, in the year ending Easter 1776, omitting fractions. | Average Expenditure on Paupers, 1783-4-5. | Expenditure 1803. | Expenditure 1815. |
|---|---|---|---|---|
| County of Hereford | £10,593 | 16,727 | 48,067 | 59,255 |
| Bedford | 16,662 | 20,977 | 38,070 | 50,370 |

By this table, it appears, that the charge on the rates, in 1815, not in two or three counties only, but taking England throughout, was double its amount in 1795; though, in 1815, the price of corn had sunk to a moderate average. A comparison of these rates in the five following years, i. e. to 1820, as digested in the poor-rate returns, ordered to be printed in July 1821, shows the same alarming tendency to increase.

| Years. | Expended for the Relief of the Poor. | Average Price of Corn per Qr. | |
|---|---|---|---|
| | £. | s. | d. |
| 1815 | 5,418,845 | 70 | 6 |
| 1816 | 5,724,506 | 61 | 10 |
| 1817 | 6,918,217 | 87 | 4 |
| 1818 | 7,890,148 | 90 | 7 |
| 1819 | 7,531,650 | 82 | 9 |
| 1820 | 7,329,594 | 69 | 5 |

By this table, it will appear, that as the price of corn in 1815 and 1820 was the same, the amount of the rates ought likewise to have been the same, with the addition of 10 per cent. for increase of population. It ought, therefore, to have been 6,000,000 in 1820, according to the scale of 1815. But it is 7,000,000, giving 1,000,000, or one-sixth of the whole, as the actual growth of five years. We shall have an opportunity of pursuing this important subject further hereafter; documents sufficient have been now laid before the reader to show its legal and statistical basis. We have only room to observe, that a plan of fixing the maximum of these rates was laid before parliament in 1821; but clogged with so many objectionable alterations in the law of settlement, that it met with little attention. Mr. Malthus makes the following important objections to the very nature of this plan: 'Under such a law, if the distresses of the poor were to be aggravated tenfold, either by the increase of numbers, or the recurrence of a scarcity, the same sum would invariably be appropriated to their relief. If, in the meantime, the statute which gives the poor a right to support, were to remain unexpunged, we shall add to the cruelty of starving them, the injustice of still professing to relieve them. If this statute were expunged or altered, we should virtually deny the right of the poor to support, and only retain the absurdity of saying that they had a right to a certain sum.' *On Population*, III., p. 353.

This objection, says an able writer in the Supplement to the Encyclopædia Britannica, equally applies to an amendment which has been since proposed, to render the maximum a gradually decreasing maximum, by subtracting from its amount 10s. or 12s. per cent. annually, till the whole was extinct. To any one acquainted with the manner in which the affairs of a parish are and must be conducted, taking the country at large, such impossibilities must occur in the execution of a law of this nature, as render it quite undeserving attention as a national measure. The business of overseer, for the first half of the year, would go on smoothly enough. By that time, three-fourths of the legal assessment would probably be spent. Then all, whatever might be their wants, must be put on short allowance, and future claimants excluded. But each of such claimants would justly consider that he had as good a right to be supported in the hour of need, as those who happened to be visited with misfortune a few months before; and those whose mischance it was to be in distress when the fixed sum was collected and expended, would be particularly ill used on being refused assistance, while so many others around them had enjoyed this advantage. If such a measure were passed, it would be virtually repealed in half the parishes of the kingdom before the expiration of five years. Besides, there is nothing in any measure of this kind, which tends to stem the progress of pauperism; nothing to prevent the numbers from annually increasing, which require public assistance. All the channels by which the main stream is supplied, as described in the beginning of this article, remain the same; why, then, should we expect that the stream itself should grow narrower, or cease to overflow its bounds? If, then, the sum collected were to be divided among all who might be in want, however their number might increase, great misery must ensue; and all the blame of it would be laid, not without much apparent justice, to the charge of the society, which undertook the support of the poor, yet supplied them so sparingly, that they must necessarily die of hunger and disease. 'The only measure which can be considered as either politically wise, or practically efficient, is one which shall gradually annihilate the system by attacking directly its vital principle, and striking at the root of the disease.'

Mr. Malthus, therefore, proposes that a regulation should be made, declaring, that no child, born from any marriage taking place after the expiration of a year from the date of the law, and no illegitimate child, born two years from the same date, shall ever be entitled to parish assistance. And, to give a more general knowledge of this law, and to enforce it more strongly on the minds of the lower classes of people, the clergyman of each parish should, after the publication of bans, read a short address, stating the strong obligation on every man to support his own children; the impropriety, and even immorality, of marrying without a prospect of being able to do this; the evils which had resulted to the poor themselves, from the attempt which had been made to assist, by public institutions, in a duty which ought to be exclusively appropriated to parents, and the absolute necessity which had, at length, appeared of abandoning all such institutions, on account of their producing effects totally opposite to those which were intended. 'This would operate as a fair, distinct, and precise notice, which no man could well mistake; and, without pressing hard upon any particular individuals, would at once throw off the rising generation from that miserable and helpless dependence upon the government and the rich, the moral as well as physical consequences of which are almost incalculable.'

We add on this subject the following more recent STATEMENT, showing the amount of the PAROCHIAL ASSESSMENTS, in each county of ENGLAND and WALES in the year ending March 25th, 1823, distinguishing in column

No. 1. The proportion levied on lands.
2. The proportion levied on dwelling-houses.
3. The proportion levied on mills and factories.
4. The proportion levied on manorial profits, &c.
5. Total.
6. The number of inhabited houses in each county.

The number of inhabited houses in each county assessed at £50, but under £110 per annum.

The number of inhabited houses in each county assessed at £110, but under £160 per annum.

The number of inhabited houses in each county assessed at £160 and all above.

| TOTAL | 4,602,252 | 1,762,950 | 247,390 | 90,909 | 6,703,501 | 2,097,066 | 35,708 | 3610 | 2627 |

Tne population return of 182[illegible], represents 2,088,156 houses in England and Wales as being inhabited in that year, another return made to parliament in the session of 1823, represents 437,626 out of that number charged with duty, on the assessed taxes in the year ending April 5th, 1822, the total value assessed being £10,168,574, and the amount of the assessment £1,180,250, about half of which amount is contributed by the 41,945 houses enumerated in the above statement. 202,628 farm houses occupied by tenants, and used bonâ fide for husbandry,—exempt leaving the occupiers of 1,447,902 out of the 2,088,156 houses inhabited in 1821 to be too impoverished to contribute to direct taxation.

There is another topic connected with the financial and statistical History of England, to which we may be allowed to advert, and on which we can supply some interesting details in this place, although in a preceding article we have in part anticipated it,—that of our numerous Assurance and Insurance Societies for lives, and against the casualties of fire, shipwreck, &c.

The following are the companies for the assurance for lives, and insurance against fires, losses by shipwreck, &c., enumerated in the late work of Mr. Babbage on this subject.

| Name of Office. | | | Nominal Capital. | Capital paid up. | Table of Mortality. | Proportion of Profit given Assured. | Periods of Division. |
|---|---|---|---|---|---|---|---|
| | | | £ | | | | |
| Ægis . . . . . | F & L | Prop. | 1,000,000 | | Same as Guardian | None | . . . . |

| West of Engld. | F & L | Prop. | 600,000 | | 10 p. c. under Northampton | None | . . . . |
| Westminster . . | L | Mixed | | | Northampton | None | . . . . |

These companies may be considered as constituted on three different plans. The first is, where all the assurers for the whole term of life are mutually responsible. They participate in the profits, and are subject to calls to replace any loss or deficiency in the funds.* This responsibility, however, is merely nominal, as a large surplus fund must necessarily accumulate from the circumstances already noticed so highly favorable to the offices. A capital to commence with is wholly unnecessary, as the receipts continue to be annually paid in, and are placed at interest in the public securities, long before any large demands can take place, and there is no danger of losses occurring from bad debts. Of societies founded on this principle of mutual assurance, there are established in London the Amicable, Equitable, the London Life Assurance and Norwich Life, and in these the assurers are entitled to share in the profits; but they do not share in the whole of them, one-third being generally reserved.

The second principle on which institutions of this kind are founded, is that of a number of persons forming a company, and raising a capital among themselves, as a guarantee for the payment of all contracts or policies which they may effect. Security to the assured, and freedom from responsibility, are the supposed advantages held out by this plan; in consideration of which the rates charged are generally as high as the preceding, though the exact sums only, named in the policies, are paid on the deaths of the parties, without additions or deductions. The offices which have adopted this plan are the Albion, British Commercial, Eagle, Globe, London Assurance, Pelican, Royal Exchange, Sun, West of England, Westminster. Whatever advantages may be supposed to attach to these offices, the assurer most undoubtedly pays very high for a security, that is merely nominal, or at least unnecessary; but we suppose the greater number of the assurers are proprietors, and as such share in the profits of the concern.

The third principle consists of a combination of these two. The proprietors subscribe a capital, relieve the assured from all loss, and responsibility, take one portion of the profits to pay the

interest of the capital, and give the assured, at certain intervals, the remainder. The Rock, the Alliance, the Guardian, the Palladium, and some others, are founded on this principle, which is, perhaps, as good as any other, though it curtails the amount of the additions which would otherwise be made to those assurers who are not proprietors, or holders of shares.

From a table given by Mr. Morgan, the actuary of the Equitable, formed from above 150,000 instances, Mr. Babbage concludes that forty-seven is about the average age at which persons assure; that is to say, as many persons assure later in life than this age, as under it; that about one-third commence between forty and fifty—nine-tenths between thirty and seventy; that about one-fifteenth of the whole are under twenty when they commence; that on a life aged forty-six, the profits per cent on the premiums demanded by the several following offices, are as follows:

| | £. | s. |
|---|---|---|
| Alliance . . . . | 30 | 2 |
| Amicable . . . . | 25 | 5 |
| British Commercial . . | 16 | 6 |
| Crown . . . . | [illegible]5 | 5 |
| Economic . . . . | [illegible] | 2 |
| Equitable . . . . | 2[illegible] | 2 |
| European . . . . | 2[illegible] | 5 |
| Guardian . . . . | 25 | 1 |
| London Assurance . . | 26 | 7 |
| Medico-Clerical . . . | 29 | 7 |
| Norwich Union . . . | 19 | 3 |
| Sun . . . . . | 30 | 9 |
| United Empire . . . | 21 | 9 |
| University . . . . | 23 | 2 |
| West of England . . | 16 | 2 |

Before, however, we can judge accurately of the comparative advantages to the assurers, this table must be viewed in conjunction with the proportion of those profits which is returned to them in the shape of a bonus; the mode of assigning that proportion; the periods at which it is so assigned; and the periods at which the assurers become entitled to participate in those profits.

Mr. Babbage says, that the only two companies (and they are those which probably rank highest in public estimation and importance) that have yet assigned a bonus to the assured, by adding a certain per centage to the amount of the policies, are the Equitable and the Rock. In this, we apprehend, he must be mistaken; at least, he is inconsistent with his own statement, wherein he had just told us that all but the ten proprietary companies profess to make certain returns of their profits; perhaps, however, they may not yet have made a commencement of fulfilling their professions. The Rock is a young establishment compared with the former, and only made its first dividend of profits in the year 1819, thirteen years after its establishment, when it is stated to have added twenty per cent. to those policies which had existed ten years. The Equitable, at various periods since the year 1782, and in two periods of ten years each ending in 1820, added to each policy, existing at the former date, 185 per cent., the average addition of ten years being £23 2*s*. 6*d*. per cent. The conclusion drawn from this comparison is important.

'A difference of £3 2*s*. 6*d*. on £20, or nearly one-sixth between two offices, may not appear very great; and it may perhaps be expected that, on a larger experience, they will approximate much more nearly to each other. That there are very sufficient reasons why this cannot be the case, and that the relative advantages of the two offices are not truly estimated by the numbers 20, and 23⅛, I shall now proceed to show. In order to render this matter, which is of considerable importance, more clear, I shall suppose two assurance offices to commence at the same time, one on the plan of the Equitable, the other on that of the Rock and some others; that each makes by its business a clear profit of £300,000 every ten years; each office awards two-thirds of the profits to the assured, but one of them, immediately on each division, transfers one-third of the profits to a body of proprietors.

'By tracing the progress of these offices through a considerable period of years, we shall see the important result produced by the deduction of one-third of the profits for the payment of those who guarantee the capital.

At the end of the first ten years, both offices divide a profit of £300,000, and two-thirds of this are added to the policies of the assurers at both offices; but at the Equitable, the other third increased during the next ten years, suppose it only at three per cent., amounts to £134,392; and at the second division, the profits of the Equitable are greater than those of the other office by this sum.

'The following table will show the sums added, at intervals of ten years, by an office on the plan of the Equitable:—

| | |
|---|---|
| At the end of the first ten years . . | £200,000 |
| At the end of the second ten years . | 289,595 |
| At the end of the third ten years . . | 329,730 |
| At the end of the fourth ten years . . | 347,709 |
| At the end of the fifth ten years . . | 355,764 |
| At the end of the sixth ten years . . | 359,373 |

'Whilst at an office in which one-third of the profit is paid to proprietors, the constant sum of £200,000 can only be added at the decennial period of division; and, in the course of sixty years, the assurers have received additions of nearly £682,000 at one office above those given by the others.

'Nor is this the whole difference; for although two-thirds is the sum nominally divided amongst the assured, since that sum is only payable on the death of their respective nominees, it is not really equal to two-thirds, and is, in fact, different for different ages. Thus suppose three assurers of the ages of twenty, thirty-five, and sixty, and that £100 is the addition awarded to each of their policies, the present value of that sum to each of these parties is £34 9*s*. 9*d*., £42 3*s*. 1*d*. and £61 7*s*. 9*d*., respectively; and even when the same sum is added to a policy on a life aged eighty, it is worth in present money only £82 2*s*. 10*d*.; this inequitable mode of apportioning them is not however so disadvantageous in a system of mutual assurers, because the reserved surplus again accumulates for the benefi of the assured at the next period of division.

'These facts show that the two-thirds, apparently given to the assured, are in reality not equal to one-half the total profits; at the same time they explain the cause of the large additions made at the Equitable, and show that it cannot be expected that any of an equal extent can ever be made by any society burdened with a permanent proprietary.'

It is deserving of notice, that up to the year 1820, the Equitable added to a policy of twenty years' date, 77 per cent; to one of thirty years' date, 161 per cent; to one of forty years' date, 280 per cent.; and to one of fifty years' date, 401 per cent.

It would be tedious to give an abstract even of what the various offices promise to do with the profits. The following, however, is a summary of about one-half of them, as given by Mr. Babbage:—

| | |
|---|---|
| Equitable, Rock, Provident, Union, | added to policies. |
| Alliance, Guardian, | added to policy, or applied to diminish premium. |
| Norwich Union, Provident, United Empire, | added to policies in proportion to amount of premiums paid. |
| Economic, European, | added to policies and interest on bonus paid annually. |
| Atlas, Law Life, | a reversionary sum equal to present bonus added to policy. |
| London Life, | applied to diminish premium, or paid immediately. |
| Amicable, | a sum equal to the average annual payment, received by the society during the last five years, divided amongst those who die in every year. |
| Palladium, | added to policies on the most equitable principles of division. |
| Hope, Imperial, | unknown. |

'Those offices which merely add the bonus to the policy are wrong on both the grounds which interest the public. In the first place, they appear to give as a bonus a larger proportion than they in reality do give, and they also distribute that bonus very unequally; the older lives having a much larger portion than the younger. In some cases, an old life will receive twice as much as a young one, and yet the same rate per cent is awarded to each.'

The following table shows the periods at which the division of profits takes place at the respective offices mentioned therein:—

| | |
|---|---|
| Alliance, Asylum, United Empire, | five years. |
| Medical and Clerical, | five or seven years. |
| Equitable, | ten years. |
| Crown, Economic, Hope, Imperial, Law Life, | unknown. |
| Amicable, London Life, | yearly. |
| Atlas, European, Guardian, Norwich Union, Palladium, Rock, Provident, Union: | seven years. |

See ASSURANCE.

We shall add to these statistical details whatever may seem necessary to give a complete picture of the existing state of the empire under the article GREAT BRITAIN.

## PART II.

### HISTORY OF ENGLAND.

1. *Of England under the Anglo-Saxons.*—We have seen (article BRITAIN) the entire success of the arms of Egbert. The kingdoms of the Heptarchy that were allowed to retain their name had lost all independent existence; and Egbert became sole master of England about the year 827. A favorable opportunity was now offered to the Anglo-Saxons of becoming a civilised people, as they were at peace among themselves, and seemed free from any danger of a foreign invasion. But this flattering prospect was soon overcast. Five years after Egbert had established his new monarchy, the Danes plundered the isle of Sheppey, and made their escape with safety. Encouraged by this success, next year they landed from a fleet of thirty-five ships. They were encountered by Egbert at Charmouth in Dorsetshire. The battle was obstinate and bloody. Great numbers of the Danes were killed, but the rest made good their retreat to their ships. They next entered into an alliance with the Britons of Cornwall; and, landing two years after in that country, made an irruption into Devonshire. Egbert met them at Hengesdown, and totally defeated them; but before he had time to form any regular plan for the defence of the kingdom, he died, and left the government to his son Ethelwulf. The reign of Egbert on the whole was most fortunate and glorious. Dr. Lingard contends, however, that there is not sufficient authority for supposing that he gave himself the title of the first king of England, and thinks that Henry of Huntingdon means by Monarcha Britannicus nothing more than 'Bretwalda,' a title which the most eminent and powerful of the princes of the Saxon Hep-

tarchy had long borne. It is clear, however, according to the admission of this writer, that he extended the authority of his original kingdom of Wessex over the far greater part of the island.

The new king was weak and superstitious. He began with dividing the kingdom, which had so lately been united, with his son or brother Athelstan. To the young prince he gave the counties of Essex, Kent, and Surrey; a division which, though it might have been productive of bad consequences at another time, was perhaps in part adopted for safety, and through fear of the Danes. These piratical barbarians impelled by the hope of plunder, scarcely ever failed of paying England an annual visit; and, though they met with many previous repulses, had on the whole gained sufficient ground in 851 for a body of them to take up their winter quarters in England. Next year they received a strong reinforcement of their countrymen in 350 vessels; and advancing from the isle of Thanet, where they had stationed themselves, they burnt London and Canterbury. Having next put to flight Brithric the governor of Mercia, they marched into the heart of Surrey, laying waste the whole country through which they passed. Ethelwulf, though little inclined or fitted for military enterprises, was now obliged to take the field. He marched against the Danes at the head of the West Saxons, and gained an indecisive and bloody victory over them; for the enemy still maintained a settlement in the isle of Thanet. They were also attacked by Ealher and Hudda, governors of Kent and Surrey; both of whom they defeated and killed. Afterwards they removed to the isle of Shepey, where they took up their winter quarters, with a design to extend their ravages the next year. In this deplorable state of his kingdom Ethelwulf undertook a pilgrimage to Rome, whither he carried his fourth and favorite son Alfred, then only six years of age. Some of our historians state that this prince had been previously sent to Rome at the age of four under the care of the bishop of Winchester. Be this as it may he certainly accompanied his father at this time, and the pontiff Leo IV. is said at Ethelwulf's desire to have conferred on him the royal unction with the ceremony of confirmation. Having passed a year at Rome Ethelwulf made a grant of 300 mancuses (about £37 10*s.* sterling) annually to the papal see. See MANCUS. On his return through France, he married Judith, daughter of the emperor Charles the Bald, who after the marriage, was crowned and seated on a throne beside her husband, at Rheims. This is the first instance of a female coronation in our history, and the West Saxons are said to have exhibited great distaste of the ceremony. When Ethelwulf landed in England, he found that his eldest son Ethelbald had conspired with the bishop of Sherburne, the ealdorman of Somerset, and others, to deprive him of the throne. Athelstan had died in the interim, and Ethelbald had in virtue of his deputed authority assumed the government of the provinces formerly committed to that prince. This strengthened his hands, and the monkish parent agreed to transfer to the heir apparent the kingdom of Wessex, and content himself with the eastern provinces formerly governed by Athelstan. Immediately after this he is said to have summoned the states of his kingdom, and conferred on the clergy a perpetual donation of tithes, for which they had contended for several centuries. It seems more probable, however, that this transaction, whatever it may in reality have amounted to, took place before his journey to Rome: as it clearly was from the first recognised throughout the kingdom of Wessex, and the grant was extended by a council held at Winchester (Lingard says in 855) to all the clergy of the Saxon nations. This concession was deemed so meritorious, that the people of both states now thought themselves secure of the favor of heaven; and therefore neglected to use the natural means for their safety. They even agreed, that, notwithstanding the desperate situation of affairs, the revenues of the church should be exempted from all burdens; even from those imposed for the immediate defence of their respective territories.

Ethelwulf died two years after his return, and left the kingdom of Kent by will to his second son Ethelbert, and that of Wessex to Ethelbald, Ethelred, and Alfred, in succession. Ethelbald now, therefore, continued to govern the kingdom of Wessex, and his brother Ethelbert was placed in possession of the eastern provinces. The former, who had strenuously objected to his father's marriage with Judith of France (then not more than twelve years of age), now gave his hand to the young widow; but his people were so scandalised at this incestuous match, that he was compelled to submit to a separation, and she retired to her native country. This lady's history is still further, however, connected with that of England: as through a subsequent marriage with Baldwin, the forester of France and earl of Flanders, she became the mother of Matilda, the wife of William I. and gave to this country a long line of kings.

Ethelbald survived his father about seven years, but no further transactions of his reign appear in our histories. By the unanimous consent of the great council of Wessex, though contrary as we have seen to his father's will, he was succeeded by his next brother Ethelbert, whose reign was, however, also short and uninteresting. But in his person the whole of his father's dominions were again united under one sceptre. The Danes or northmen, the year previous to his death, penetrated to the city of Winchester and plundered it; but were defeated on their retreat by the ealdormen of Hampshire and Berkshire. In Kent and the isle of Thanet, as well as in Northumbria, they were successful.

Ethelred I. succeeded to his brother in the year 866; and the whole of his reign was disturbed by the irruptions of the Danes. The king defended himself with great bravery, being seconded in all his military enterprises by his brother Alfred. In this reign, the Danes first induced the East Angles to enter into an alliance with them, and furnish them with horses, to make an irruption into Northumberland, where they seized upon York. Osbright and Ælla, two Northumbrian princes who attempted to rescue the city, were defeated and killed. Encouraged by this success, the northmen pene-

trated into Mercia, took up their winter quarters at Nottingham, and thus threatened the kingdom with a total subjection. From this post, however, they were dislodged by Ethelred and Alfred, who forced them to retire into Northumberland. Their restless disposition, however, did not suffer them to continue long in one place. They broke again into East Anglia; defeated and took prisoner Edmund the tributary king, whom they afterwards murdered; and committed every where the most barbarous ravages. In 871 they advanced to Reading; from whence they infested the neighbouring country by their incursions. The Mercians, desirous of recovering their independence, refused to join Ethelred with their forces; so that he was obliged to march against the Danes, attended only by the West Saxons, his hereditary subjects. Several actions ensued, in which the Danes were said to be unsuccessful; but, being continually reinforced from their own country, they became every day more and more formidable to the English. During the confusion and distress in which the nation was now involved, Ethelred died of a wound he had received, and left to his brother Alfred a kingdom almost totally subdued by foreigners.

Alfred ascended the throne in 871, being then only twenty-two years of age. His great virtues and shining talents saved his country from that ruin which seemed almost unavoidable. His exploits against the Danes, his dangers and general character, have already engaged our attention under the article Alfred. Having settled the nation in such a manner, that he may be justly esteemed the founder of the monarchy, as well as of the free constitution of England, he died in 901, leaving the kingdom to his second son Edward the elder. And here we may conveniently compare the comparative accuracy of Mr. Hume and Dr. Lingard. We have examined the authorities of the latter with regard to Alfred sufficiently to believe that whenever that prince is concerned, Mr. Hume is to be followed with caution. The splendid qualities of a prince who, in a barbarous age, and amid scenes of devastation, though constantly tortured by the agony of an inward disease, displayed a taste and an intellect so far above his contemporaries, have inspired the historian with a partiality which has blinded him to the defects of his idol. Alfred's conduct in the first years of his reign was far from blameless. He is accused of having given full scope to the indulgence of his passions. There is good authority for saying, that he neglected the administration of justice, and treated the complaints of his subjects with contempt. Even in the exercise of his military and political functions, negligence, as well as imprudence, may be traced. He was more than once surprised, and he more than once forgot himself, so far as to purchase with money that tranquillity which successful valor can alone procure. We mention these things, not to detract from the glory of that great prince, but to show how far Mr. Hume disregarded facts, in representing him as free from blemish. Alfred ripened with his years: adversity did not teach him in vain. He fled from his throne, only to re-ascend it more completely fitted for the discharge of all his duties. But the events which drove him from the throne appear, from the narrative of Hume, to be not a little mysterious. The sovereign of England—harassed indeed by foreign invaders, but exerting himself against them with success for several years, and not meeting with any signal disaster, all at once, without any great battle, without any cause assigned except the despair of his people, and no immediate reason for their despair, except the capture of Chippenham,—becomes a fugitive, seeking safety in woods and morasses. The apparent mystery which hangs over this revolution, disappears, when we keep in view three circumstances, which are generally overlooked. 1st. Alfred, in strict propriety of speech, was not king of England. Northumbria, Mercia, and East Anglia had retained a separate, though not independent, existence under Egbert. In the time of Ethelred, Northumbria and East Anglia were conquered by the Danes. In 874 Mercia had the same fate. The connexion of these provinces with the English crown was thus annihilated. Alfred's authority, therefore, never extended beyond the limits of Wessex, and perhaps some adjacent districts of East Anglia: so that it was not the king of England who was driven from his throne, but a king of Wessex, who had an enemy in the heart of his dominions, and was surrounded by enemies on every side. 2dly. Alfred's military operations had not been attended with that success, which the declamatory language of historians, leads us to ascribe to them. This is proved by the necessity, to which he often found himself reduced, of trying to buy a peace, and by the footing which Gothrun obtained in Essex. 3dly. The circumstance which was the immediate cause of the subversion of Alfred's throne was a military operation of Gothrun, by which the king was compelled to seek his personal safety in flight, all his followers were dispersed, and no means were left to his subjects of joining in any regular plan of defence. This event is one of the most curious in our history; we shall extract Dr. Lingard's account of it. 'This sudden revolution arose from the policy of Gothrun, the most artful of the Northmen. That chieftain, on his retreat out of Wessex, had fixed his residence at Gloucester, and rewarded the services of his veterans by dividing among them the lands in the neighbourhood. But, while this peaceful occupation seemed to absorb his attention, his mind was actively employed in arranging a plan of warfare, which threatened to extinguish the last of the Saxon governments in Britain. A winter campaign had hitherto been unknown in the annals of Danish devastation: after their summer expedition, they had always devoted the succeeding months to festivity and repose: and it is probable that the followers of Gothrun were as ignorant as the Saxons of the real design of their leader. On the first days of the year 878 they received an unexpected summons to meet him on horseback at an appointed place: on the night of the 6th of January they were in possession of Chippenham, a royal villa on the left bank of the Avon. There is reason to believe that Alfred was in the place when the alarm was given: it is certain that he could not be at any great distance. From Chippenham Gothrun dispersed his cavalry in different directions over the neigh-

bouring counties: the Saxons were surprised by the enemy before they had heard of the war: and the king saw himself surrounded by the barbarians without forces and almost without attendants. At first he conceived the rash design of rushing on the multitude of his enemies; but his temerity was restrained by the more considerate suggestions of his friends, and he resolved to reserve himself for a less dangerous and more hopeful experiment. To elude suspicion, he dismissed the few thanes who were still near his person, and endeavoured, alone and on foot, to gain the centre of Somersetshire. There he found a secure retreat in a small island, situated in a morass formed by the conflux of the Thone and the Parret, which was afterwards distinguished by the name of Ethelingey, or Prince's Island.

'Though the escape of Alfred had disappointed the eager hopes of the Danes, they followed up their success with indefatigable activity. The men of Hampshire, Dorset, Wilts and Berkshire, separated from each other, ignorant of the fate of their prince, and unprepared for any rational system of defence, saw themselves compelled to crouch beneath the storm. Those who dwelt near the coast, crossed with their families and treasures to the opposite shores of Gaul; the others sought to mitigate by submission the ferocity of the invaders, and, by the surrender of a part, to preserve the remainder of their property. One county alone, that of Somerset, is said to have continued faithful to the fortunes of Alfred: and yet, even in the county of Somerset, he was compelled to conceal himself in the fens, while the ealdorman Æthelnoth with a few adherents wandered in the woods.'

Mr. Hume is scarcely less inaccurate in narrating the steps by which Alfred re-ascended the throne. He tells us the story of Alfred's disguise as a harper, under which he entered the Danish camp, and remained for some days in the tent of Gothrun. The tale is pretty, but it was unknown to Alfred's contemporaries, and appeared for the first time two centuries after his death. Mr. Hume represents the Danes as taken by surprise, and as submitting almost without resistance; 'taking advantage of his previous knowledge of the place,' says Mr. Hume (vol. i. p. 83), 'he directed his attack against the most unguarded quarter of the enemy. The Danes, surprised to see an army of English whom they considered as totally subdued, and still more astonished to hear that Alfred was at their head, made but a faint resistance, notwithstanding their superiority of numbers, and were soon put to flight with great slaughter.' Dr. Lingard shows that they were not surprised, and that they fought with desperate valor. See *Lingard*, vol. i. p. 186.

The beginning of Edward's reign was disturbed by those intestine commotions from which the wise and politic Alfred had taken so much pains to free the nation. Ethelwald, son to king Ethelbert, claimed a right to the throne, and took possession of Winburne, where he seemed determined to hold out to the last extremity. On the approach of Edward, however, with a powerful army, he first fled into Normandy, and afterwards into Northumberland, where the Danes, lately subdued by Alfred, but very impatient of peace, readily declared for him. Ethelwald having thus connected himself with the Danish tribes, went to Denmark, whence he returned with a great body of these banditti, and was joined by the Danes of East Anglia and Mercia. He made an irruption into Gloucester, Oxford, and Wilts; and, having ravaged the country, retired with his booty before the king could approach him. Edward revenged himself by leading his forces into East Anglia, and ravaging it in like manner He then ordered his army to retire: but the Kentish men, greedy of plunder, staid behind, and took up their quarters at Bury. Here they were assaulted by the Danes; but made so obstinate a defence, that though their enemies gained the victory, it was bought by the loss of their bravest men, and among the rest of the usurper Ethelwald. The king, now freed from the attempts of so dangerous a rival, concluded an advantageous peace with the East Angles. He next engaged in reducing the Northumbrians, and for this purpose equipped a fleet, when the latter thinking the whole of the king's forces were on ship-board, entered his territories with all their troops. The king, however, was better prepared than they expected. He attacked them on their return at Tetenhall, in Staffordshire, put them to flight, recovered the booty, and pursued them with great slaughter into their own country. The rest of Edward's reign was a scene of continued and successful actions against the Northumbrians, East Angles, the Danes of Mercia, and others from Denmark. He fortified Chester, Eddesbury, Warwick, Cherbury, Buckingham, Towcester, Maldon, Huntingdon, and Colchester, and vanquished the celebrated Thurketil, a Danish chieftain whom he obliged to retire into France. He also subdued the East Anglians, Northumbrians, and several tribes of the Britons; and even obliged the Scots to make submissions. He died in 925, and was succeeded by Athelstan his natural son.

This prince ascended the throne without much opposition, as the legitimate children of Edward were too young to rule a nation so much exposed both to foreign invasion and domestic broils. The etheling Alfred, however, a nobleman of considerable power, entered into a conspiracy against him. It is said, that this nobleman was apprehended upon strong suspicion only, but without any certain proof. He offered to swear to his innocence before the pope; and in those days it was supposed that none could take a false oath in presence of such a sacred person, without being visited by an immediate judgment from God. Alfred was accordingly conducted to Rome, and took the oath required of him before pope John X. The words were no sooner pronounced, we are told, than he fell into convulsions, of which he expired in three days. The king, fully convinced of his guilt, confiscated his estate, and made a present of it to the monastery of Malmesbury. This accident proved the means of establishing the authority of Athelstan in England. But finding the Northumbrians bore the English yoke with impatience, he gave Sithric, a Danish no-

bleman, the title of king of Northumberland; and, to secure his friendship, gave him his own sister Editha in marriage. This was productive of bad consequences. Sithric died the year after his marriage with Editha; upon which Anlaf and Godfrid, Sithric's sons by a former marriage, assumed the sovereignty without waiting for Athelstan's consent. They were, however, soon obliged to yield to the superior power of that monarch. The former fled to Ireland; and the latter to Scotland, where he was protected by king Constantine III., who was importuned by Athelstan to deliver up his guest, and even threatened with an invasion if he did not comply. Constantine, detesting such treachery, advised Godfrid to make his escape. He did so, turned pirate, and died soon after. Athelstan, resenting this conduct of Constantine, invaded Scotland, and reduced him, it is said, so low, that he was obliged to make the most humble submissions. This, however, is denied by all the Scottish historians. Constantine, after the departure of Athelstan, entered into a confederacy with Anlaf, who subsisted by his piracies, and with some of the Welsh princes who were alarmed at the increase of Athelstan's power. The confederates made an irruption into England at once; but Athelstan meeting them at Brunanburgh, or Brumbsbury in Northumberland, gave them a total overthrow. Anlaf and Constantine made their escape with difficulty, leaving the greater part of their men dead on the field of battle. After this period, Athelstan enjoyed his crown in tranquillity. He passed a remarkable law, for the encouragement of commerce; viz. that a merchant who had made three long voyages on his own account, should be admitted to the rank of a thane or gentleman; and died in 941, after reigning sixteen years.

He was succeeded by his brother Edmund I. On his accession he found the kingdom disturbed by the restless Northumbrians, who were, however, soon reduced; and Edmund ensured the peace of the kingdom, by removing the Danes from Mercia, where they had been allowed to settle, as he found they took every opportunity to introduce their countrymen into the kingdom. He also conquered Cumberland from the Britons. This country, however, he bestowed upon Malcolm king of Scotland, upon condition that he should do homage for it, and protect the north of England from all future incursions of the Danes. Edmund was unfortunately murdered in Gloucester by one Leolf a notorious robber. This man had been formerly sentenced to banishment; yet had the boldness to enter the hall where the king himself dined, and to sit at table with his attendants. Edmund immediately ordered him to leave the room. The villain refused to obey; upon which the king leaped upon him, and seized him by the hair. Leolf then drew a dagger, and gave the king a wound, of which he instantly died, A. D. 946, in the sixth year of his reign.

As the children of Edmund were too young, his brother Edred succeeded to the throne. The beginning of his reign, as well as those of his predecessors, was disturbed by the rebellions and incursions of the Northumbrian Danes. On the appearance of Edred with an army, however, they immediately submitted; but before the king withdrew his forces, he laid waste their territories by way of punishment. No sooner had he departed, than they rose in rebellion a second time. They were again subdued; and the king took effectual precautions against their future revolts, by placing English garrisons in all their towns, and appointing an English governor to watch their motions, and suppress their insurrections. In the reign of Edred, the celibacy of the clergy first began to be preached under the patronage of Dunstan. This pretended saint had obtained such an ascendancy over Edred, who was naturally superstitious, that he not only directed him in affairs of conscience, but in the most important matters of state. He was placed at the head of the treasury; and, being thus possessed of great power at court, was enabled to accomplish the most arduous undertakings. Professing himself a partisan of the most rigid monastic rules, and having introduced celibacy among the monks of Glastonbury and Abingdon, he endeavoured to render it universal among the clergy throughout the kingdom. The monks generally embraced the pretended reformation; after which they inveighed bitterly against the vices and luxury of the age. When other topics of defamation were wanting, the marriages of clergymen became a sure object of invective. Their wives received the appellation of concubines, or some other more opprobrious name. The secular clergy, on the other hand, who were numerous and rich, defended themselves with vigor, and endeavoured to retaliate upon their adversaries. The people were thrown into the most violent ferments; but the monks, being patronised by Edred, gained ground greatly upon their opponents. Their progress, however, was somewhat retarded by the king's death, which happened in 955 after a reign of nine years. He left children; but, as they were infants, his nephew Edwy, son to Edmund, was placed on the throne

The new king was not above sixteen or seventeen years of age, at his accession. His reign is only remarkable for the tragical story of his queen Elgiva. She was a princess of the royal blood, with whom Edwy was deeply enamoured, but, being his second or third cousin, was within the degrees of affinity prohibited by the canon law. Edwy, however, hearkening only to the dictates of his passion, married her, contrary to the advice of the more dignified ecclesiastics. The monks on this occasion were particularly violent; and Edwy therefore determined not to second their ambitious projects. But he soon found reason to repent his having provoked such dangerous enemies. On his coronation day, while his nobility were indulging themselves in riotous mirth in the hall where they had assembled, Edwy withdrew to another apartment, to enjoy the company of his beloved queen and her mother. Dunstan guessed the reason of his absence; with unparalleled assurance he burst into the queen's apartment; and upbraiding Edwy with his lasciviousness, as he termed it, pushed him back into the hall where the nobles were assembled. The king determined to resent such a daring insult. He required from Dunstan an account of the administration of the treasury

during the late reign. The monk, probably unable to give a just account, refused to give any; upon which Edwy accused him of malversation in his office, and banished him the kingdom. We have noticed the general accuracy of our modern historian Dr. Lingard. On this subject, in a previous article (see DUNSTAN), we presumed to question it: and, on reflection must consider his whole account of this ecclesiastic as tainted with prejudice and grossly partial to his own church. He is introduced to us as a young thane, whose thoughts a dangerous sickness turned from worldly pursuits to the monastic state, and whose zeal, disinterestedness, and charities, while he served the church of Glastonbury, attracted public notice. Not a word is uttered concerning the early licentiousness of which he is accused; nay, the prudence of his biographer robs him of the glory of all those exploits, which gave him his power while he lived, and after his death placed him on the list of the saints. Why are we not told of the cell in which he secluded himself from the world? a cell in which he could neither stand erect, nor stretch out his limbs during repose. Why is the noted adventure of the devil and the red-hot pincers passed over in total silence? These circumstances are essential to a faithful picture of the age and of the individual; and they stand upon authority, which Dr. Lingard in other cases deems unobjectionable. Why then are they omitted? Because in the present day they would not contribute to Dunstan's fame. Again, the synod which met at Colne to discuss the keenly agitated question concerning the pretensions of the monastic orders, the floor fell in; some were killed, many were hurt: the beam on which Dunstan's chair stood, was the only one that did not give way. These facts Dr. Lingard admits: but he blames the historians who suspect and accuse Dunstan as the author of the catastrophe. The charge, he says, is a mere fiction. It is no fiction. It is only an inference; and, whether it be just or not, is a fair subject of dispute. Dr. Lingard's zeal for the reputation of Dunstan has led him to give a new coloring to the transactions of Edwy's reign. He has corrected Hume in some minute particulars; yet, upon the whole, the general features of Edwy's story are delineated by that author more faithfully than by Dr. Lingard.

On Dunstan's departure the whole nation was in commotion about his sanctity, and the king's impiety. These clamors as they had been begun, so they were kept up and increased by the clergy, till at last they proceeded to the most outrageous violence. Archbishop Odo sent a party of soldiers to the palace. They seized the queen, and burnt her face with a red-hot iron; after which they carried her by force into Ireland, there to remain in perpetual exile. The king, finding it in vain to resist, was obliged to consent to a divorce from her, which was pronounced by Odo. A catastrophe still more dismal awaited Elgiva. She had been cured of her wounds, and had even found means to efface the scars with which her persecutors had hoped to destroy her beauty. She then came to England, with a design to return to the king, whom she still considered as her husband. Unfortunately, however, she was intercepted by a party of soldiers sent for that purpose by the primate. Nothing but her most cruel death could now satisfy this wretch and his accomplices. She was hamstringed at Gloucester, and expired in a few days. The minds of the English were at this time so much sunk in superstition, that the monstrous inhumanity above mentioned was called a judgment from God upon Edwy and his spouse for their dissolute life, i. e. their virtuous love to each other. They even proceeded to rebellion against their sovereign; and having raised to the throne Edgar, the younger brother of Edwy, at that time only thirteen years of age, they soon put him in possession of Mercia, Northumberland, and East Anglia. Edwy being thus confined to the southern counties, Dunstan returned, and took upon him the government of Edgar and his party; but the death of Edwy soon removed all difficulties, and gave Edgar peaceable possession of the government. Dr. Lingard's view of the events subsequent to Dunstan's exile is thus given:—'Soon after this transaction Edwy appears to have married, an event which might have been expected to put an end to the connexion between him and his mistress. Whether on that occasion Ethelgiva was committed to the care of her relations or of her husband, we are ignorant; but the king, either instigated by his passion, or moved by her solicitations, carried her off by force, and placed her in one of the royal farms. Archbishop Odo undertook to remove the scandal, by enforcing the punishment which the laws awarded against women living in a state of concubinage. Accompanied by his retainers, he rode to the place, arrested Ethelgiva, probably in the absence of her lover, conducted her to the sea-side, and put her on board a ship, in which she was conveyed to Ireland. At his return to court he waited on Edwy, and in respectful and affectionate language endeavoured to justify his own conduct, and to sooth the exasperated mind of the young prince.' (pp. 234, 235). Elgiva or Ethelgiva, is here provided with a husband of whom history knows nothing. This writer, indeed, supposes the mother to have been the object of Edwy's attachment, and, as she had a daughter, he is entitled to infer that she once had a husband. But history makes no mention of this husband: he might have been dead at the time of Edwy's accession. The supposition, that it was the mother whom Edwy loved, is so far as we know unwarranted. Dr. Lingard gives us no authority for it: and in the absence of clear proof to the contrary, we are entitled to hold that a youth of seventeen or eighteen was more likely to become enamoured of the daughter than of the mother. Two other important circumstances, quite new in history, are also contained in this passage; the marriage of Edwy, and his carrying off Elgiva by force. They rest upon the authority of two passages in two manuscript lives of St. Oswald, the one anonymous, the other written about ninety years after Eadmer by Senatus, prior of Worcester. The anonymous writer says, 'Rex, sub uxore propria alteram adamavit, quam et rapuit.' The words of Senatus are, 'Rex exarsit in quandam, quam spreta fide tori subintroductam habebat;' and then he

goes on to mention Dunstan's opposition and banishment. These authorities seem the weakest that could be imagined. The force used against Elgiva is hinted at only by the anonymous biographer of Oswald; and the words of Senatus 'spreta fide tori' are vague enough to admit of more than one interpretation. There is no specification of person in either; so that the authors appear to have had no accurate knowledge of what they pretend to relate. If Senatus be interpreted as insinuating that Edwy was married, then, contrary to Dr. Lingard's narrative, this marriage preceded the banishment of Dunstan; and Edwy must be supposed to have involved himself without any reason in a matrimonial engagement, at the very moment he was so violently attached to another as to forget every ordinary calculation of prudence. The supposition of his carrying off Elgiva by force is altogether inconsistent with acknowledged facts. Elgiva's feelings and circumstances were not such as to render violence necessary. To make force requisite, she must have been in the custody of Dunstan's faction: and we know that she was not in their power, till Odo sent her to Ireland. From the nature of the case, therefore, as well as from the weakness of the evidence adduced, we cannot admit, that Edwy carried off Elgiva by force, or that he was married to another. And we are confirmed in this conclusion by considering, that neither of these circumstances has been mentioned by the monkish historians of the age. Their silence on such topics is decisive. Had it been possible to have magnified any of Edwy's failings into the crime of adultery, they would not have spared him and his mistress that reproach. It is remarkable too how gently the outrage of Odo is represented as being 'an endeavour to enforce the law.'

The reign of Edgar, proved one of the most fortunate in the English history. He took the most effectual methods both for preventing tumults at home and invasions from abroad. He quartered a body of disciplined troops in the north, to repel the incursions of the Scots, and to keep the Northumbrians in awe. He built a powerful navy; and that he might keep the seamen in the practice of their duty, as well as present a formidable front to his enemies, he commanded the fleet from time to time to make the circuit of his dominions. The greatness of Edgar, which is much celebrated by our historians, is mainly to be attributed to the harmony which reigned between him and his subjects; and the reason of this perhaps was, that he espoused all the measures suggested by Dunstan and the monks, who had acquired a great ascendancy over the people. He enabled them to accomplish their favorite scheme of dispossessing the secular canons of the monasteries, and consulted them not only in ecclesiastical, but also in civil affairs. On these accounts he is celebrated by the monkish writers with the highest praise: though it is plain, from some of his actions, that he was a man who could be bound neither by the ties of religion nor humanity. He broke into a convent, and carried off by force a nun of the name of Editha. His spiritual instructor, Dunstan, for this offence, obliged the king, not to separate from his mistress, but to abstain from wearing his crown for seven years; Edgar, however, was not to be satisfied with one mistress. Happening to lodge at the house of a nobleman who had a very beautiful daughter, he without ceremony asked her mother to allow the young lady to pass a night with him. She promised compliance: but secretly ordered a waiting maid, named Elsteda, to steal into the king's bed when the company were gone, and to retire before day-break. Edgar, however, detained her by force, till day-light discovered the deceit. His love is said to have been now transferred to this girl; who became his favorite mistress, and maintained great ascendancy over him till his marriage with Elfrida. The circumstances of this marriage were yet more criminal than those above mentioned. Elfrida was daughter and heiress to the earl of Devonshire. The fame of her exquisite beauty was spread over all England; and Edgar formed a design of marrying her. He communicated his intention to earl Athelwold his favorite; and ordered him to visit the earl of Devonshire, and give him an opinion of Elfrida. Athelwold went as he was desired; but fell so deeply in love with the young lady, that he resolved to sacrifice his fidelity to his passion. He returned to Edgar and reported, that her charms were by no means extraordinary, and would have been totally overlooked in a woman of inferior station. He observed, however, that he thought her parentage and fortune made her a very advantageous match; and therefore, if the king gave his consent, he would himself make proposals to her father. Edgar consented, and Athelwold was married to Elfrida. After this event he used his utmost efforts to keep his wife from court, that Edgar might have no opportunity of observing her charms. The king, however, soon informed of the truth, told Athelwold that he intended to pay him a visit, and to be made acquainted with his new wife. The earl could make no objection; he only desired a few hours to prepare his house; and, confessing the whole intrigue to Elfrida, begged of her not to attempt to exert her influence over the king. The lady, however, was not so easily reconciled to being duped of a crown: she is said to have taken particular pains at the toilet, and Edgar immediately conceived a violent passion for her. To gratify it he seduced Athelwold into a wood, under pretence of hunting, where he stabbed him with his own hand, and afterwards married his widow. The reign of this tyrant is remarkable for the great encouragement it offered to foreigners to settle in the realm. They corrupted, it is alleged, the former simple manners of the nation: but of this there seems to be no great reason to boast. Their more extended intercourse certainly tended to enlarge their views, and cure them of illiberal prejudices and rustic manners. Another remarkable incident of this reign is, the extirpation of wolves from England. The king took great pleasure in hunting and destroying these animals. At last he found they had taken shelter in the mountains and forests of Wales. Upon this he changed the tribute imposed upon the Welsh princes by Athelstan, into an annual tribute of 300 wolves' heads; which produced such diligence in hunting them, that they were at last ex-

terminated. Edgar died in 958, after a reign of sixteen years.

He left a son, Edward, whom he had by his first wife the daughter of earl Ordmer; and another named Ethelred, by Elfrida. She proved, as might have been expected, ambitious, haughty, treacherous, and cruel. The principal nobility, therefore, were greatly averse from the succession of her son Ethelred, which would unavoidably throw considerable power into the hands of his mother, as he was only seven years of age. Edward was therefore selected for the prince, at fifteen years of age. But Elfrida opposed his advancement with all her influence; until Dunstan overcame every obstacle, by anointing and crowning him at Kingston; upon which the whole kingdom submitted to his authority. The only remarkable occurrence in this reign was the final victory obtained by the monks over the secular clergy, who were now expelled from the convents. Though this had been nearly accomplished by Edgar, the secular clergy had still those partisans in England who made considerable opposition; but these were not silenced by the pretended miracles, and authority of Dunstan. Edward lived four years after he was raised to the throne, in perfect submission to his council at the head of which were the ecclesiastics. Incapable of any treacherous intention himself, he suspected none in others. Though his stepmother, in particular, had opposed his succession, he had always behaved towards her with the greatest respect; and expressed on all occasions great affection for his brother Ethelred. Being one day hunting in the neighbourhood of the castle where Elfrida resided, he paid her a visit unattended by his retinue: and, after mounting his horse to return, requested some liquor to be brought him. While he was holding the cup to his head, we are told, a servant of Elfrida stabbed him behind. The king, finding himself wounded, clapped spurs to his horse; but soon becoming faint, from the loss of blood, he fell from the saddle, and his foot being entangled in the stirrup he was dragged along till he expired. His body was found by his attendants, and privately interred at Wareham. His subjects bestowed upon this amiable prince the appellation of martyr, and fancied that miracles were wrought at his tomb. Elfrida built monasteries, and submitted to many penances to atone for her guilt; but even in that barbarous age she could never regain the good opinion of the public.

After the murder of Edward, his brother Ethelred II. succeeded to the throne without opposition. As he was a minor, the Danes began to renew their incursions. They first, in 981, landed at Southampton from seven vessels; and, having ravaged the country, retired with impunity carrying a great booty with them. In 987 they made a similar attempt on the west coast, which was attended with success. Thus encouraged they landed in Essex, and, having defeated and killed Crithnot a prince of that county, laid waste all the neighbouring provinces. In this extremity Ethelred, surnamed, on account of his preposterous conduct, the Unready, bribed the enemy with £10,000 to depart the kingdom; according to advice said to have been given to him by Siricius archbishop of Canterbury, and some of the degenerate nobility. It was attended with the success that might have been expected. The Danes appeared next year off the eastern coast. But, in the mean time, the English had determined to assemble, at London, a fleet capable of repulsing the enemy, and only failed of success through the treachery of Alfric duke of Mercia. Having been formerly banished the kingdom, and finding great difficulty in getting himself restored to his former dignity, he now trusted not to his services or the affections of his countrymen, but to the influence he had over his vassals, in the midst of the public calamities. These he seemed determined to promote as far as he could. The English had formed a plan for surrounding and destroying the Danish fleet; when Alfric not only gave the enemy notice of the design, but deserted with his squadron the night before the engagement. Ethelred, in revenge, took Alfgar, Alfric's son, and ordered his eyes to be put out. It was found, however, impossible to deprive Alfric of the government of Mercia. In 993 the Danes under the command of king Sueno, or Sweyn, and the Norwegians conducted by Olaus, sailed up the Humber, and destroyed all around them. A powerful army was assembled to oppose these invaders; but through the treachery of the three leaders, all men of Danish extraction, the English were totally defeated.

Encouraged by constant success, the Danes at length entered the Thames in ninety-four vessels, and laid siege to London. The inhabitants, however, made a brave defence, and the besiegers were obliged to retire. In revenge they laid waste Essex, Sussex, and Hampshire; and, seizing the horses of these districts, were enabled to penetrate into the more inland counties, and threatened the entire kingdom with subjection. Ethelred and his nobles had now recourse to their former expedient. They sent ambassadors to the two northern kings, to whom they promised subsistence and tribute, provided they would, for the present, put an end to their ravages and depart the kingdom. These terms were agreed to, and the Danes peaceably took up their quarters at Southampton. Olaus even paid a visit to Ethelred, and received the rite of confirmation from the English bishops. The king also made him many presents; and Olaus promised never more to molest the English territory; which promise he religiously observed. After the departure of Olaus with his Norwegians, Sueno, though less scrupulous, was obliged also to leave the kingdom. But this compromise procured only a short relief. The Danes soon re-appeared in the Severn, and having ravaged Wales, as well as Cornwall and Devonshire, sailed round, and, entering the mouth of the Tamar, completed the ruin of the two counties. Then, returning to the Bristol Channel, and penetrating into the interior by the Avon, they carried fire and sword into Dorsetshire. In 998 they changed the seat of the war, and, after ravaging the Isle of Wight, entered the Thames and Medway, where they laid siege to Rochester, and defeated the Kentish men. After this victory the whole province was made a scene of slaughter and devastation. These miseries forced the English to consult for com-

mon defence; but the weakness of the king, the divisions among the nobility, the treachery of some, the cowardice of others, and the want of concert in all, frustrated every endeavour; and their fleets and armies either came too late to attack the enemy, or were repulsed with disgrace. Devoid both of prudence and unanimity, they once more had recourse to their old expedient, and offered the Danes a large sum if they would conclude a peace and depart. These ravagers now required the payment of £24,000, which the English submitted to give, and thus procured a temporary relief. The Danes were also engaged by another motive to depart from England at this time. They were recalled by their countrymen in Normandy, who were hard pressed by Robert king of France, and found it difficult to defend their settlements against him. It is probable also that Ethelred, observing the close connexion of the Danes with one another, was desirous of procuring an alliance with that formidable people. For this purpose, being a widower, he paid his addresses to Emma, sister to Richard II., duke of Normandy. They were accepted; the princess came over to England, and was married to the king, A.D. 1001.

Though the Danes had been long established in England, and the similarity of their language with that of the Saxons had invited them to an early union with the natives; they had as yet found so little of civilised manners among the English, that they retained all their ancient ferocity, and valued themselves only on their character for bravery: and the English princes had been so well acquainted with their superiority in this respect, that Athelstan and Edgar had been accustomed to keep in pay large bodies of Danish troops. These mercenaries attained to such a height of *luxury*, according to the old English writers, that they combed their hair once a-day, bathed themselves once a-week, changed their clothes frequently, and by these effeminate arts, as well as by their military character, rendered themselves so agreeable to the fair sex, that they debauched the wives and daughters of many English families. They were of course also ready always to betray them to the foreign Danes, and to associate themselves with every straggling party which came from the continent. The animosities between the native English and the settled Danes, had, from these causes, risen to a great height; when Ethelred, from that barbarous policy commonly adopted by weak princes, resolved upon a general massacre of the latter. On November 13th, 1002, secret orders were despatched to commence this bloody business every where on the same day, and the festival of St. Brice, which fell on a Sunday, the day on which the Danes usually bathed themselves, was chosen for this purpose. His barbarous orders were executed with the utmost exactness. Neither sex nor age was spared. Even Gunilda, sister to the king of Denmark, who had married earl Paling, and had embraced Christianity, was, by the advice of Edric earl of Wilts, seized and condemned to death by Ethelred, after seeing her children and husband butchered before her face. This unhappy princess, in the agonies of her despair, foretold that her murder would soon be avenged by the total ruin of the English. On the subject of this massacre, Mr. Hume says, 'Almost all the ancient historians speak of this massacre of the Danes as if it had been universal, or as if every individual of that nation throughout England had been put to death. But the Danes were almost the sole inhabitants in the kingdoms of Northumberland and East Anglia, and were very numerous in Mercia. This representation of the matter seems highly improbable. Great resistance must have been made, and violent wars ensued, which was not the case. The account given by Wallingford, though he stands single, must be admitted as the only true one. We are told that the name of lurdane, lord Dane, for an idle lazy fellow, who lives at other people's expense, came from the conduct of the Danes who were put to death. But the English princes had been entirely masters for several generations; and only supported a military corps of that nation. It seems probable, therefore, that these Danes only were put to death.'

The prophecy of Gunilda was exactly fulfilled. In 1003 Sueno and his Danes, who wanted only a pretence to renew their invasions, appeared off the western coast, and threatened vengeance for the slaughter of their countrymen. The English took measures for repulsing the enemy; but were defeated through the treachery first of Alfric, and then of Edric, a still greater traitor, who had married the king's daughter, and succeeded Alfric in the command of the British armies. The Danes, therefore, ravaged the whole country. Agriculture was neglected, a famine ensued, and the kingdom was reduced to the utmost degree of misery. At last the infamous expedient of buying a peace was again resorted to; and the departure of the Danes was purchased in 1007 at the expense of £30,000. The English endeavoured to employ this interval in making preparations against their return, which they had reason soon to expect. A law was made, ordering the proprietors of eight hides of land to provide themselves of a horseman and a complete suit of armour; and those of 310 hides to equip a ship for the defence of the kingdom. By this means a formidable armament was raised. There were 243,600 hides in England, and the ships equipped were therefore very numerous. The cavalry was 30,450 men. All hopes of success from this equipment, however, were disappointed by the factions, animosities, and dissensions of the nobles. Edric had caused his brother Brightric to advance an accusation of treason against Wolfnoth governor of Sussex, the father of the famous earl Godwin; who, knowing the power and malice of his enemy, deserted with twenty ships to the Danes. Brightric pursued him with a fleet of eighty sail; but his ships being shattered in a tempest, and stranded on the coast, he was suddenly attacked by Wolfnoth, and all his vessels were destroyed. The treachery of Edric frustrated every plan of future defence, and the whole navy was at last scattered. By these fatal miscarriages, the enemy had leisure to overrun the whole kingdom. They had now, indeed, obtained such a footing, that they could hardly have been expelled, even though the nation had been unanimous. But so far did dissension prevail, that the

governors of one province refused to march to the assistance of another; and were at last terrified from assembling their forces for the defence of their own. At last another peace was bought with £48,000; but this did not procure the usual temporary relief. The Danes, knowing that they were masters, took the money, and continued their devastations. They levied a further contribution of £8000 on the county of Kent alone; murdered the archbishop of Canterbury, who had refused to countenance this exaction, and made all the English nobility give hostages for their good behaviour. At last, Ethelred himself, dreading equally the violence of the enemy and the treachery of his own subjects, fled, in 1013, into Normandy, whither he had already sent his queen Emma, and her sons Alfred and Edward. The duke received his unfortunate guests with a generosity which does honor to his memory. The king had not been above six weeks abroad, however, when he heard of the death of Sueno, and received an invitation from the prelates and nobility to resume the kingdom. But his imprudence was incurable. His son-in law Edric, notwithstanding his repeated treasons, still retained such influence at court, that he instilled into the king jealousies of Sigefert and Morcar, two of the chief nobles of Mercia. Edric enticed them into his house, where he murdered them; while Ethelred partook of the infamy of this action, by confiscating their estates, and confining the widow of Sigefert in a convent. She was a woman of singular beauty and merit; and in a visit which was paid her, during her confinement, by prince Edmund the king's eldest son, she inspired him with so violent an affection, that he released her from the convent, and soon after married her without his father's consent.

In the mean time, Canute, the son and successor of Sueno, proved an enemy no less terrible to the English than his father had been. He ravaged the eastern coast with merciless fury; and put ashore all the English hostages at Sandwich, after having cut off their hands and noses. He was at last obliged to return to Denmark, but, in a short time, he returned, and continued his depredations along the south coast. He then broke into the counties of Dorset, Wilts, and Somerset; where an army was assembled against him under the command of prince Edmund and duke Edric. The latter still continued his perfidious machinations; and, after endeavouring in vain to get the prince into his power, dissipated the army, and then deserted to Canute with forty vessels. Edmund was not disheartened by this treachery. He again assembled his forces, and was in a condition to give the enemy battle. Ethelred, however, had now such frequent experience of the treachery of his subjects, that he had lost all confidence in them. He remained in London, affecting sickness, but, in reality, from an apprehension that they intended to buy their peace by delivering him up to his enemies. The army called aloud for their sovereign to march at their head against the Danes, and, on his refusal, they were so discouraged, that all the preparations which had been made became ineffectual, for the defence of the kingdom. Edmund, deprived of all regular resources for the maintenance of the soldiers, was obliged to commit similar ravages to those practised by the Danes; and after making so many fruitless expeditions into the north, which had submitted entirely to Canute's power, he returned to London, where he found every thing in confusion by the king's death.

Ethelred II. died in 1016, after an unhappy reign of thirty-five years; and was succeeded by his eldest son Edmund II., surnamed Ironside. He possessed abilities sufficient to have saved his country from ruin, had he come sooner to the throne: but it was now too late. He bravely opposed the Danes, however, notwithstanding every disadvantage; till, at last, the nobility of both nations obliged their kings to come to a compromise, and divide the kingdom between them by treaty. Canute reserved to himself Mercia, East Anglia, and Northumberland. The southern parts were left to Edmund. This prince survived the treaty only about a month, being murdered at Oxford by two of his chamberlains, accomplices of Edric. After the death of Edmund, nothing was left for the English but submission to Canute. The least scrupulous of mankind, however, dare not, at all times, openly commit injustice. Canute, therefore, before he seized the dominions of Edwin and Edward, the two sons of Edmund, suborned some of the nobility to depose, that, in the last treaty with Edmund, it had been agreed that, in case of Edmund's death, Canute should either be successor to his dominions, or tutor to his children. This evidence, supported by the great power of Canute, was sufficient to obtain his election as king of England. It is observable, says Dr. Lingard, that the ancient writers almost always speak of our kings as elected. Edwy's grandmother, in her charter (Lyc. App. IV.), says he, was chosen 'gecoren.' A remnant of this custom still obtains in our coronation ceremony, in which the people have the monarch proposed to their choice. Mr. Turner says, 'that the Norman conquest terminated the power of the Witenagemot, and changed the crown for an hereditary succession.' But this is to be doubted.

2. *Of England under the Danish princes.*—Immediately after Canute's accession to the throne, he sent the two sons of Edmund to the court of Sweden, on pretence of their being educated there; but charged that prince, it is said, to put them to death as soon as they arrived. The Swedish monarch did not comply with this request; but transferred them to the care of Stephen, king of Hungary. The elder Edwin was afterwards married to Stephen's sister; but, he dying without issue, that prince gave his sister-in-law, Agatha, daughter of the emperor Henry II., in marriage to Edward, the younger brother; and she bore him Edgar Atheling; Margaret, afterwards queen of Scotland; and Christina, who retired into a convent. Canute was obliged at first to make great concessions to the nobility, but he afterwards put to death many of those in whom he could not put confidence; and, among the rest, the traitor Edric, whom he cut down before his nobles with a battle axe, and his body was thrown into the Thames. Further to conciliate the people, he married Emma the widow of

Ethelred II., promising that he would leave the children he should have by that marriage heirs to the crown after his decease. The English were at first displeased with Emma for marrying the mortal enemy of her husband; but at the same time were glad to find at court a sovereign to whom they were accustomed, and who had already formed connexions with them: and thus Canute, besides securing by his marriage an alliance with Normandy, gradually acquired, by the same means, the confidence of his new subjects. The most remarkable transaction of his reign, besides those mentioned under the article CANUTE, is his expedition to Scotland against Malcolm II., whom he forced to do homage for the county of Cumberland, which the Scotch at that time possessed. After this Canute passed four years in peace, and died at Shaftsbury; leaving three sons, Sweno, Harold, and Canute.

The letter written by this prince to his subjects from Rome, as preserved by Spelman, is an interesting memorial of the age and of his own character:—

'Canute, king of all Denmark, England, and Norway, and of part of Sweden, to Egelnoth the metropolitan, to archbishop Alfric, to all the bishops and chiefs, and to all the nation of the English, both nobles and commoners, greeting. I write to inform you that I have lately been at Rome, to pray for the remission of my sins, and for the safety of my kingdoms, and of the nations that are subject to my sceptre. It is long since I bound myself by vow to make this pilgrimage; but I had been hitherto prevented by affairs of state, and other impediments. Now, however, I return humble thanks to the almighty God, that he has allowed me to visit the tombs of the blessed apostles Peter and Paul, and every holy place within and without the city of Rome, and to honor and venerate them in person. And this I have done, because I had learned from my teachers, that the apostle St. Peter received from the Lord the great power of binding and loosing, with the keys of the kingdom of heaven. On this account I thought it highly useful to solicit his patronage with God.

'Be it moreover known to you, that there was, at the festival of Easter, a great assemblage of noble personages with the lord the pope John, and the emperor Conrad, namely, all the chiefs of the nations from mount Gargano to the nearest sea, who all received me honorably, and made me valuable presents; but particularly the emperor, who gave me many gold and silver vases, with rich mantles and garments. I therefore took the opportunity to treat with the pope, the emperor, and the princes, on the grievances of my people, both English and Danes; that they might enjoy more equal law, and more secure safeguard in their way to Rome, nor be detained at so many barriers, nor harassed by unjust exactions. My demands were granted both by the emperor, and by the king Rodulf, to whom the greater part of the barriers belong: and it was enacted by all the princes, that my men, whether pilgrims or merchants, should, for the future, go to Rome and return in full security, without detention at the barriers, or the payment of unlawful tolls.

'I next complained to the pope, and expressed my displeasure that such immense sums were extorted from my archbishops, when, according to custom, they visited the apostolic see to obtain the pallium. A decree was made that this grievance should cease. Whatever I demanded, for the benefit of my people, either of the pope, or the emperor, or the princes, through whose dominions lies the road to Rome, was granted willingly, and confirmed by their oaths, in the presence of four archbishops, twenty bishops, and a multitude of dukes and nobles. Wherefore I return sincere thanks to God, that I have successfully performed whatever I had intended, and have fully satisfied all my wishes.

'Now, therefore, be it known unto you all, that I have dedicated my life to the service of God, to govern my kingdoms with equity, and to observe justice in all things. If, by the violence or negligence of youth, I have violated justice heretofore, it is my intention, by the help of God, to make full compensation. Therefore I beg and command those to whom I have confided the government, as they wish to preserve my friendship, or save their own souls, to do no injustice either to rich or poor. Let all persons, whether noble or ignoble, obtain their rights according to law, from which no deviation shall be allowed, either from fear of me, or through favor to the powerful, or for the purpose of supplying my treasury. I have no need of money raised by injustice.

'I am now on my road to Denmark, for the purpose of concluding peace with those nations who, had it been in their power, would have deprived us of both our crown and our life. But God has destroyed their means: and will, I trust, of his goodness preserve us, and humble all our enemies. When I shall have concluded peace with the neighbouring nations, and settled the concerns of my eastern dominions, it is my intention to return to England, as soon as the fine weather will permit me to sail. But I have sent you this letter beforehand, that all the people of my kingdom may rejoice at my prosperity. For you all know that I never spared nor will spare myself, or my labor, when my object is the advantage of my subjects.

'Lastly, I entreat all my bishops, and all the sheriffs, by the fidelity which they owe to me and to God, that the church-dues, according to the ancient laws, may be paid before my return; namely, the plough-alms, the tithes of cattle of the present year, the Peter-pence, the tithes of fruit in the middle of August, and the kirk-shot at the feast of St. Martin, to the parish church. Should this be omitted, at my return I will punish the offender by exacting the whole fine appointed by law. Fare ye well.'

Sueno, the son of Canute by his first marriage with Alfwena, daughter of the earl of Hampshire, was, on the death of that prince, crowned in Norway; Canute, whom Emma had borne, was in possession of Denmark; and Harold, who was full brother to Sueno, was at that time in England. This prince succeeded to the crown of England; though it had been stipulated that Emma's son Canute should be considered the heir. But the former, being on the spot, obtained

possession of his father's treasures, and all the resources of the government. As Canute, however, was supported by earl Godwin, a civil war was likely to ensue, when a compromise was made; by which it was agreed, that Harold should reign in London, and over all the provinces north of the Thames, while the possession of the south should remain to Canute. Till that prince should appear, and take possession of his dominions, Emma fixed her residence in Winchester, and ruled in the name of her son. Harold reigned four years, during which time, the only memorable action he performed was a most infamous piece of treachery.—Alfred and Edward, the two sons of Emma by Ethelred, paid a visit to their mother in England. But in the mean time, earl Godwin being gained over by Harold, a plan was laid for the destruction of these princes. Alfred was accordingly invited to London by Harold, with many professions of friendship; but when he had reached Guildford, about 600 of his train were murdered in the most cruel manner, he himself was taken prisoner, his eyes were put out, and he was conducted to the monastery of Ely, where he soon after died. Edward and Emma, apprised of the fate which awaited them, fled beyond sea, the former into Normandy, the latter into Flanders; while Harold took possession of all his brother's dominions without opposition.—He died in April 1039.

Canute II., surnamed the Hardy, and hence commonly called Hardicanute, succeeded his brother Harold without opposition. His government was extremely violent and tyrannical. It was, however, but of short duration. He died in 1041 of a debauch at the marriage of a Danish lord.

3. *Of England under the restored Saxon line.*—After the death of Hardicanute, a favorable opportunity was offered to the English, for shaking off the Danish yoke. Sueno, king of Norway, the eldest son of Canute, was absent; and, as the two last kings had died without issue, there appeared none of that race whom the Danes could support as successor to the throne. For this reason, the eyes of the nation were naturally drawn towards prince Edward, who happened to be at court when the king died. But it was feared that his succession would be opposed by earl Godwin, who was by far the most powerful nobleman in the kingdom. A declared animosity subsisted between the prince and Godwin, on account of the connexion of the latter with the murderers of his brother Alfred; and this, it was thought, he never would forgive. But common friends interposed, and, representing the necessity of a good understanding, obliged them to lay aside these animosities, and to concur in restoring liberty to their native country. Godwin only stipulated that Edward, as a pledge of his sincere reconciliation, should promise to marry his daughter Editha. This proposal was agreed to: Edward was crowned king of England, and married Editha, but the marriage proved a source of discord. Editha, though an amiable woman, could never obtain the confidence and affection of her husband. It is even said, that during the whole course of her life, he imposed upon himself a vow of continence; a species of behaviour highly celebrated by the monkish writers of the age, and which contributed, in no small degree, to his acquiring the titles of Saint and Confessor. Though the neglect of his daughter could not fail to awaken Godwin's former enmity, it was necessary to choose a more popular ground on which to vent his complaints. He therefore began to censure the influence which the Normans had in the public affairs, and a declared opposition took place between him and these favorites. In a short time this animosity broke out into great violence. Eustace, count of Bologne, having paid a visit to the king, passed by Dover on his return, where, one of his train being refused access to a lodging, he wounded the master of the house in the affray, and his townsmen revenged the insult by the death of the stranger. The count and his train now took arms, and slew the opponent of their countryman. A tumult ensued: near twenty persons were killed on each side; until Eustace, being overpowered with numbers, was obliged at last to fly. He complained to the king, who gave orders to earl Godwin, in whose government Dover lay, to punish the inhabitants. But this nobleman refused to obey the command, and endeavoured to throw the whole blame on Eustace and his followers. Edward was displeased, and threatened to make him feel his resentment, in case he finally refused to comply. Upon this, Godwin assembled a powerful army, in pretence of repressing some disorders on the frontiers of Wales, and marched directly towards the king's residence at Gloucester. Edward, perceiving his danger, for he was unattended by any considerable force, applied to Siward, duke of Northumberland, and Leofric, duke of Mercia, to hasten to him with their followers. Godwin, in the mean time, suffered himself to be deceived by negociations, till the king's army became so powerful, that he was not able to cope with it. He was therefore obliged to fly with his family to Flanders, where he was protected by earl Baldwin, together with his three sons, Gurth, Sueno, and Tosti; the last of whom had married Baldwin's daughter. Harold and Leofwin, two other sons of Godwin, took shelter in Ireland. After the flight of this turbulent noble, he was proceeded against as a traitor by king Edward. His estates, and those of his sons were confiscated; queen Editha was confined in a monastery; and the great power of this family, which had become formidable to the crown itself, seemed to be totally overthrown. Godwin, however, soon found means to retrieve his affairs. Having hired several ships, and manned them with his followers, he attempted to make a descent at Sandwich. The king, informed of his preparations, also equipped a fleet which Godwin could not resist; he therefore retreated into the Flemish harbours. On his departure, the English dismissed their armament. This Godwin had expected, and therefore kept himself in readiness for a favorable opportunity. He immediately put to sea, and, sailing to the Isle of Wight, was joined by Harold with a squadron which he had collected in Ireland. Being thus master of the sea, Godwin entered the harbours on the southern coast, seized all the English ships, and, being joined by great numbers of his former

vassals, sailed up the Thames, and appeared before London. The approach of such a formidable enemy threw the whole city into confusion. The king alone seemed resolved to defend himself to the last; but the interposition of many of the nobility, together with the submission of Godwin himself, at last produced an accommodation. It was stipulated that the earl should give hostages for his good behaviour, and that all foreigners should be banished the kingdom; after which Edward, sensible that he had no power to detain the hostages, sent them over to his kinsman the young duke of Normandy. Soon after this reconciliation, Godwin died as he was sitting at table with the king. He was succeeded in the government of Wessex, Sussex, Kent, and Essex, and in the office of steward of the household, a place of great power, by his son Harold, a man no less ambitious than his father; and, as he was of much greater abilities, he became a more dangerous enemy to Edward than even Godwin himself had been. The king knew no better expedient to prevent the increase of Harold's power, than by creating him a rival in the person of Algar, son of Leofric, duke of Mercia, whom he invested with the government of East Anglia. Harold, however, after some disputes, ultimately got the better of his rival, and banished him the kingdom. Algar, returning soon after with an army of Norwegians, invaded East Anglia; but his death in a short time freed Harold from all further apprehensions from that quarter. His power was still further increased soon after, by the accession of his brother, Tosti, to the government of Northumberland; and Edward, apprehensive that he would attempt to usurp the crown after his death, resolved to appoint a successor. He therefore sent a deputation into Hungary, to invite over his nephew, Edward, son to his elder brother, who was the only remaining heir of the Saxon line. That prince accordingly came over with his children, Edgar Atheling, Margaret, and Christina, but died a few days after his arrival. This event threw the king into greater perplexity than ever. Being resolved to exclude Harold, if possible, he had formerly designed to nominate his kinsman, William, duke of Normandy, as his successor; but finding that the English would more easily acquiesce in a sovereign of the Saxon line, he had sought his brother's descendants. The death of his nephew, however, at this time, and the inexperience of young Edgar, made him resume his former intentions in favor of the duke of Normandy, though his aversion to hazardous enterprises engaged him to postpone their execution. Harold, in the mean time, increased his popularity by all possible means. He had no suspicion of the duke of Normandy as a rival; but, as he knew that a son and grandson of earl Godwin were in the hands of that prince, he feared that they might be made use of as checks upon his ambition, in case he attempted afterwards to ascend the throne. He therefore prevailed upon Edward to consent to the release of these hostages; and having obtained his acquiescence, set out for Normandy, to bring them to England, attended by a numerous retinue. The motives of this journey of Harold's are, however, very obscure. The Norman writers say that he was sent on a message from Edward to the duke of Normandy, stating that he had nominated him his successor: others that he was merely making an occasional excursion along the channel, when driven over to the coast of France. Being driven, however, by a tempest on the dominions of Guy, count of Ponthieu, he was detained prisoner, and an exorbitant sum demanded for his ransom. Harold found means to acquaint William with his situation, when the duke of Normandy, desirous of gaining Harold over to his party, commanded Guy to restore him to his liberty. Upon this Harold was immediately delivered over to the Norman ambassador, and conducted to Rouen. William received him with great apparent friendship, but soon acquainted him with his pretensions to the English crown, and asked his assistance in the execution of his scheme. Harold was surprised, but, being in the duke's power, feigned a compliance with his desires, and promised to second to the utmost of his ability the will of king Edward. Still more to secure him to his interest, William promised him his daughter in marriage, and required him to confirm his promise of friendship by an oath. Harold readily complied; and, to make the oath more binding, William is said privately to have conveyed under the altar on which it was taken, reliques of some of the most revered martyrs; and when Harold had performed the ceremony he showed him the reliques, and admonished him to observe his solemn engagement. Harold, however, was no sooner at liberty, than he found himself master of casuistry sufficient to excuse the breaking of an oath, which had been extorted from him; and which, if kept, might be attended with the subjection of his country to a foreign power. He continued to practise every art to increase his own popularity; and availed himself with great adroitness of two occurrences at this time, which exhibited him to advantage. The Welsh had for some time made incursions into England, and had lately annoyed that kingdom so much, that Harold determined to undertake an expedition against the invaders. Having prepared some light armed foot to pursue them into their fortresses, cavalry to scour the open country, and a squadron of ships to attack them by sea, he reduced them to such distress, that they were obliged to purchase peace by sending the head of Griffin, their prince, to Harold, and submitting to the government of two Welsh noblemen appointed by Edward. The other incident was no less honorable to Harold. Tosti, his brother, had been created duke of Northumberland, but, being of a tyrannical disposition had treated the inhabitants with great cruelty and they rose in rebellion against him. Morcar and Edwin, two brothers, grandsons of the great duke Leofric, joined in the insurrection; and the former, being elected duke, advanced with an army to oppose Harold, who had been commissioned by the king to reduce and punish this faction. Before the armies engaged, Morcar endeavoured to justify his conduct, and represented to Harold, that Tosti had behaved in such a manner, that no one, not even a brother, could defend him without infamy: that the Northumbrians

were willing to submit to the king, but required a governor that would pay some attention to their privileges, and they trusted that Harold would not defend in another that violent conduct from which his own government had always been free. This speech, accompanied with a detail of well supported facts, induced Harold to abandon his brother's cause; and, returning to Edward, he persuaded him to pardon the Northumbrians, and confirm Morcar in his government. He even married the sister of that nobleman, and, by his interest, procured Edwin, the younger brother, to be made governor of Mercia. Tosti, in a rage, departed the kingdom, and took shelter in Flanders with Baldwin, his father-in-law; while William of Normandy saw that now he had nothing to expect from Harold, who plainly intended to secure the crown for himself.

Edward died in 1066, aged sixty-five, and was succeeded by Harold II., with as little opposition as if he had been the lawful heir. The very day after Edward's death, he was anointed and crowned by the archbishop of York. The whole nation seemed happy to swear allegiance to him. But he did not long enjoy that station, to obtain which he had taken so much pains, and for which he seemed to be well fitted. His brother, Tosti, provoked at his success, exerted against him every enemy whom he could influence. The duke of Normandy was also enraged to the last degree at his perfidy; but, before he commenced hostilities, sent an embassy to England, upbraiding Harold with his breach of faith, and summoning him to resign the kingdom. Harold replied, that the oath with which he was reproached had been extorted by the well-grounded fear of violence, and for that reason could never be regarded as obligatory: that he never had any commission, either from the late king or the states of England, who alone could dispose of the crown, to make any tender of the succession to the duke of Normandy; and if he, a private person, had assumed so much authority, and had even voluntarily sworn to support the duke's pretensions, the oath was unlawful, and it was his duty to take the first opportunity of breaking it: that he had obtained the crown by the unanimous suffrages of the people; and should show himself totally unworthy of their favor, did he not strenuously maintain those liberties with which they had entrusted him; and that the duke, if he made any attempt by force of arms, should experience the power of a united nation, conducted by a prince, who, sensible of the obligations imposed on him by his royal dignity, was determined that the same moment should put a period to his life and to his government. This answer was according to William's expectations; and he therefore had already made preparations for invading England. He was encouraged and assisted in this enterprise by Howel, count of Brittany, Baldwin, earl of Flanders, the emperor Henry IV. and pope Alexander II. The latter declared Harold a perjured usurper; denounced excommunication against him and his adherents; and sent William a consecrated banner, and a ring with one of St. Peter's hairs in it. He was ultimately enabled to assemble a fleet of 300 vessels, on board of which were embarked 60,000 men, and many distinguished personages. To embarrass the affairs of Harold more completely, William excited Tosti, in concert with Harfager, king of Norway, to infest the English coasts; and the confederates, having collected a fleet of 350 ships, sailed up the Humber, and committed great depredations in the neighbourhood. They were opposed by Morcar, earl of Northumberland, and Edwin, earl of Mercia, who were, however, defeated. But Harold having, on the news of this invasion, assembled a considerable army, engaged the enemy at Strandford, and, after a bloody battle, was declared victor. Tosti and Harfager were killed in the action, and their fleet fell into the hands of Harold, who generously allowed Olaus, the son of Harfager, to depart with twenty vessels. He had scarcely accomplished his victory, when news were brought that the Normans were landed in Sussex. Harold's expedition had at this time considerably weakened his army. The action itself had cost him his bravest men; and he disgusted the rest by refusing to distribute the spoils among them He hastened, however, by rapid marches, to repel the new invader; but, though he was reinforced from London and other places with fresh troops, his friends were dispirited. Gurth, his brother, a man of great prudence and bravery, became apprehensive of the event; and entreated the king to avoid, for a time, a general engagement; or at least not to hazard it in person. But Harold was deaf to every thing like delay or compromise. Accordingly on the 13th October, 1066, the two armies met near Hastings, in Sussex, and prepared to decide, in the memorable battle of that name, who was to be master of England.

The night before the battle was passed very differently in the two camps. The English are said to have spent it in riot and disorder; the Normans in prayer. When, in the morning, both armies prepared for battle, William divided his into three lines; the first, headed by Montgomery, consisting of archers and light armed infantry; the second, commanded by Martel, of his bravest heavy battalions, ranged in close order; his cavalry, at whose head he placed himself, formed the third line, and were so disposed that they stretched beyond the infantry, and flanked each wing. Having given the signal of battle, the whole of his forces moved forward at once, and singing the famous song of Roland, a peer of Charlemagne's, advanced with alacrity upon the enemy. Harold had taken advantage of a rising ground, and, having constructed trenches to secure his flanks, resolved to stand upon the defensive, and to avoid all action with the Norman cavalry, his own being inferior. The Kentish men were placed in the van; the Londoners guarded the standard; and the king, accompanied by his valiant brothers, Gurth and Leofwin, dismounting from horseback, placed himself at the head of his infantry, and expressed a resolution to conquer or perish. The first attack of the Normans was desperate, but was received with great valor by the English: and after a furious conflict, which remained long undecided, the former, overcome by the difficulty of the ground and hard pressed by the enemy, began to give

way. Confusion was rapidly spreading among his troops, when William hastened, with a select band, to their relief, and restored their courage. The English then began to waver; and, the duke ordering his second line to advance, renewed the attack with fresh forces. Finding that the enemy, aided by the advantage of ground, and animated by the example of their prince, still made a formidable resistance, he suddenly commanded his forces to retreat. The artifice succeeded; the inexperienced troops of Harold were allured from their vantage ground, and, heated by the action, precipitated themselves into the plain. William now ordered the infantry to face about, and the cavalry to advance at the same instant upon their pursuers. The English were at once repulsed and driven back to the hill with great slaughter; where, however, being rallied again by the brave Harold, notwithstanding their loss, they maintained their post, and continued the combat. The duke tried the same stratagem a second time, with the same success; but, even after this doubtful advantage, he found a great body of the English, who, in firm array, seemed determined to dispute the victory with him. He therefore ordered his heavy-armed infantry to advance, while his archers, placed behind, galled the enemy, who were exposed by the situation of the ground. By this arrangement he at last prevailed. Harold was slain by an arrow, while fighting with great bravery at the head of his men. His brothers shared the same fate; and the English, discouraged by their fall, gave ground on all sides, and were pursued with great slaughter by the Normans. Thus was gained this decisive and hard-fought battle, which lasted from morning till sunset. William had three horses killed under him; and it is said to have cost him nearly 15,000 Normans. The loss was still more considerable on the English side. On the dead body of Harold being brought to the victor, he restored it, without ransom, to his mother.

We cannot better introduce, than in this place, those *Supplementary Observations* on the Anglo-Saxon period of our history, which the researches of modern writers (particularly Mr. Turner and Dr. Lingard), enable us to make.

Throughout the Anglo-Saxon period, Dr. Lingard has enjoyed the advantage of Mr. Turner's previous labors. Milton, it will be remembered, describes the various struggles for power during this portion of our history, as not more worthy a distinct narrative than the conflicts of kites and crows; and it was long the habit of our historians to neglect it accordingly. Hume disposes of the six centuries of important events which it involves—its connexion with the foundations of our monarchy, the history of parliament, the genius of our laws and language, the trial by jury, &c., in one-third of his first volume. But to Mr. Turner and Dr. Lingard are we indebted for what may now be regarded as a complete illustration of its claims. Of no portion of our annals may the student of English history obtain a more accurate knowledge in his mother tongue; and the valuable information these gentlemen unite to furnish, is a lasting memorial of the importance of exploring the most thorny paths of history. This period occupies nearly the whole of the first volume of Dr. Lingard's work, in 4to.

The writer here exhibits the ancient union of an elective with an hereditary character in our monarchy. The cyning, or king, was the noblest of the ethel, or noble-born. Before the light of Christianity had penetrated their superstitions in each of the Saxon dynasties, he could trace his origin to Woden. A religious veneration thus surrounded his person and family, which it became one of the first efforts of the Christian priesthood to continue, in coronation ceremonies and episcopal consecration. But the witan, or witenagemot, regularly elected the prince before he could be crowned. Looking with whatever feelings of regard and hope on the family of their former chiefs, they decreted upon the particular branch of it most eligible for the vacant throne. Hence we find, in the same coronation ceremonies, an elective rite of 'recognition,' as it has been called in modern times. The contemporary biographer of Dunstan (apud Boll. tom. iv. Maii 344), says 'ab universis Anglorum principibus communi *electione*.' He also intimates that Wessex and Mercia had not yet coalesced into one kingdom: 'ut in utraque plebe regum numeros nominaque suppleret *electus*.'

The witenagemot, the embryo of our modern parliament, was an assembly of the great 'and wise men,' both of church and state. The Anglo-Saxon kings call them 'meorum sapientium archontum, conciliatorum meorum, my witan,' &c. Their functions were both legislative and judicial. But Dr. Lingard can find nothing *representative* in the character of any of its members. They were principally the spiritual and temporal thanes who held lands immediately of the crown, and who could command the services of those military vassals, without whose assistance the laws of that period could not have been executed. The signatures of many of their acts and decisions, which have come down to us, do not exceed thirty in number, according to this writer, and never amount to sixty. They usually consist of the names of the king and his sons, and sometimes that of the queen; those of a few bishops and abbots, one or two abbesses, and about the same number of temporal and spiritual lords. There exists no proof that the accompanying vassals were admitted to any share in their deliberations, although they are frequently 'mentioned as looking on and applauding.'

Dr. Lingard disputes the representation of Mr. Hume and others, who regard the Norman Conquest as introducing the feudal system into this country. He traces the germs of that system in the earliest periods of the Anglo-Saxon government; and contends that they flourished in full luxuriance long before its termination. At the conquest, its various obligations and services only changed their names. In illustration of the strong tie by which the Saxon vassal held himself bound to his lord (the root of all the other feudal obligations), our author adverts to the memorable story of the murder of Cynewulf, king of Wessex. This story will also illustrate another feature in the Anglo-Saxon character—the fero-

city of their revenge. Thirty-one years after the death of Sigebyrcht, the predecessor of Cynewulf, Cyneheard, his brother, returned to the neighbourhood of Winchester to avenge his death. He was accompanied by eighty-four adherents.

'It chanced one evening that the king left Winchester with a slender retinue, to visit a lady at Merton, to whom he was warmly attached. Cyneheard stole silently from his retreat, followed with caution the footsteps of the monarch: and in the dead of the night surrounded the residence of his mistress. Cynewulf was asleep: his attendants were dispersed in the neighbouring houses. At the first alarm he arose, seized his sword, and descended to the door, where he descried his enemy; and, springing forward, aimed a desperate blow at the head of Cyneheard. The wound, which was but slight, was quickly revenged by the weapons of the conspirators. Roused by the noise of the combatants, and the shrieks of the women, the king's attendants hastened to his assistance: but they found him breathless, and weltering in his blood. It was in vain that Cyneheard offered them their lives and possessions. They scorned his proposals: and, after a long conflict, were all slain, with the exception of a Briton, who, in quality of hostage, had been detained in the court of Cynewulf; even he was severely wounded.

'Early in the morning the news arrived at Winchester. The earldoman Osric, and Wiverth the thane, immediately mounted their horses, and rode to Merton, followed by their retainers. Cyneheard met them at the gate to justify his conduct, and solicit their friendship. He pleaded the obligation of revenging the wrongs of his family: asserted his claim to the throne: offered them valuable possessions, and bade them recollect that many of his friends were their kinsmen. 'Our kinsmen,' they replied, 'are not dearer to us than was our lord. To his murderers we will never submit. If those who are related to us wish to save their lives, they are at liberty to depart.' 'The same offer,' returned the followers of Cyneheard, 'was made to the king's attendants. They refused it: we will prove to day that our generosity is not inferior to theirs.' Impatient of delay, Osric forced the barrier: he was opposed with the most desperate intrepidity; and the battle was terminated only by the failure of the combatants. Of Cyneheard's eighty-four companions one alone was saved. He was found among the slain, covered with wounds, but still alive; and owed his preservation to this fortunate circumstance, that he was the godson of Osric.'

We have noticed Dr. Lingard's efforts to rescue the memory of the celebrated Dunstan from obloquy. Mr. Turner confirms our protestant antipathy to the character of this intriguing and ambitious ecclesiastic. He shows him to have been a principal artificer in that system of pious frauds, by which the church obtained so lucrative an ascendancy over our Anglo-Saxon princes; and respecting which, it is his only excuse that his education would render him in part the dupe and the victim of them. He seems to have been born for better things; and was certainly better employed in painting 'a robe for a lady, which she afterwards embroidered,' than in following his sovereign into the privacy of domestic life and dragging him back to an Anglo-Saxon banquet—although it was a coronation feast. But this outrage, and the subsequent cruelties said to be committed by Dunstan, partly on Elgiva, or Ethelgiva, Dr. Lingard, we have seen, in substance denies; and attributes almost incredible vice to the character of the young prince, to relieve that of the monk.

The copious 'Appendix I.' on the polity, feudal customs, ranks, laws, &c. of the Anglo-Saxons, is a very valuable portion of Dr. Lingard's work. We have adverted to some of his remarks on the prevalence of the feudal system amongst them. In their administration of justice he discovers the origin of most of our present courts of law. The 'sac and soc' was the lowest species of jurisdiction, perpetuated in the manorial courts of the Normans, and in our present courts leet and courts baron. The hundred motes assembling every month, under the presidency of the ealdorman or reeve, decided the more weighty affairs of the hundred, and was a public meeting for transacting and confirming important private business. Once a year an extraordinary meeting of the hundred mote was held, at which every male above twelve years of age was required to be present; and, on some occasions, the ealdorman called to his assistance the wise men of the neighbouring hundred, or the third part of the county—the 'tything.' The shire mote was of still higher dignity, and was held twice a year, in spring and autumn. All great proprietors of land were summoned, and the bishop and ealdorman, or earl, presided with equal authority. Here the laws of the witenagemot were recited; a definite judgment pronounced in all ordinary suits; and vows of obedience renewed to the king. The witenagemot, under the presidency of the monarch, had an unlimited control over the whole system. We should gladly extract this writer's entertaining account of the criminal proceedings of these courts, and particularly of the trials by ordeal, but our limits only permit a reference to them. The Anglo-Saxon crimes were those of every semi-barbarous people, drunkenness, theft, and homicide; the love of vengeance, and the perpetuation of family feuds. Their excellencies—personal courage, and a devoted attachment to their chiefs, and their own political institutions.

In fine, on the comparative merits of Mr. Hume and Dr. Lingard, as historians, let the reader compare the account given by the former of the introduction of Christianity (it is a delicate subject for both writers) into the kingdoms of the Anglo-Saxon octarchy, with the following simple and animated passage of Dr. Lingard's work.

'At the death of Cealwin, Ethelbert had acquired (by what means we are not informed) the dignity of Bretwalda, and his authority was admitted by all the Saxon princes south of the Humber. While in possession of this dignity, he received intelligence that forty strangers had landed on the Isle of Thanet. These were Augustine and his associates, partly Gauls, partly Italians, whom pope Gregory the Great

had sent for the benevolent purpose of converting tne pagans. Ethelbert could not be unacquainted with the Christian religion. It was probably the religion of the majority of the British slaves in his dominions: it was certainly professed by his queen, Bertha, the daughter of Charibert, king of Paris. The Saxon prince received the missionaries under an oak, in an open field, at the suggestion of his priests, who told him that in such a situation the spells of the foreign magicians would lose their influence. At the appointed time Augustine was introduced to the king. Before him were borne a silver cross, and a banner representing the Redeemer; behind him his companions walked in procession, and the air resounded with the anthems which they sung in alternate choirs. As soon as the interpreter had explained the object and motives of their mission, Ethelbert replied that he had no wish to abandon the gods of his fathers for a new and uncertain worship: but that as the intention of the strangers was benevolent, and their promises were inviting, they might preach without molestation, and should be supported at his expense. This favorable answer filled them with joy; and they proceeded to Canterbury, chanting as they went, the following prayer:—'By thy great mercy, O Lord, turn away, we beseech thee, thy anger from this thy city and thy holy temple, for we are sinners—hallelujah.' On the feast of Pentecost, in the year 597, Ethelbert professed himself a Christian, and received the sacrament of baptism; and, on the following Christmas, 10,000 of his subjects followed the example of their sovereign.' Vol. 1. pp. 80—2.

The corresponding passage in Hume is introduced in his best manner, offering a fair picture of the pagan superstitions and political prejudices, which were subdued in this peaceful extension of the faith. The reflections of Gregory on the sight of some British youths exposed as slaves at Rome, and the professions of Ethelbert above alluded to, are admirably wrought into the narrative; but ought our readers to forget, that one-half of it is defiled by extracts from the correspondence of Gregory and Augustine, which no considerate parent would suffer to be read in his family; and that for the satisfaction of our young gentlemen who consult this historian for a knowledge of these events still more objectionable matter is appended in a long Latin note.

The conversion of Northumbria followed that of Kent, through the marriage of the daughter of Ethelbert to Edwin. Mr. Hume admits the ability and prudence of this prince, his hesitation about receiving the Christian doctrine, and his severe and long examination of its evidences. But the narrative of Bede, after which he here writes, (see his margin), contains the following beautiful episode on the claims of the Christian religion.

'Having taken his resolution, Edwin called an assembly of his witan, or counsellors, and required each to state his sentiments on the subject. The first who ventured to speak was Coiffi, the high priest, who, instead of opposing, advised the adoption of the foreign worship. His motive was singular. No one, he said, had served the gods more assiduously than himself, and yet few had been less fortunate. He was weary of deities who were so indifferent or so ungrateful, and would willingly try his fortune under the new religion. To this profound theologian succeeded a thane, whose discourse, while it proves the good sense of the speaker, exhibits a striking picture of national manners. He sought for information respecting the origin and destiny of man. 'Often,' said he, 'O king, in the depth of winter, while you are feasting with your thanes, and the fire is blazing on the hearth in the midst of the hall, you have seen a bird pelted by the storm, enter at one door and escape at the other. During its passage it was visible; but whence it came, or whither it went, you knew not. Such, to me, appears the life of man. He walks the earth for a few years; but what precedes his birth, or what is to follow after his death, we cannot tell. Undoubtedly, if the new religion can unfold these important secrets, it must be worthy our attention.'

'Paulinus, the missionary, now explained the principal doctrines of Christianity, and Coiffi declaring himself a convert, headed a party to set fire to the neighbouring pagan temple of Godmundham.' All this our popular historian dismisses by noticing only the conduct of the priest Coiffi.

We are surprised, however, that this intelligent writer affords us no summary of the state of the arts, and such sciences as were cultivated among the Anglo-Saxons. Can he have forgotten their love of music? Their cathedral chanting? Their illuminated missals, and other MSS.? Or their architecture? On these interesting topics we have only room for a few extracts from the important work of Mr. Turner.

Of their *music* and ecclesiastical *chanting*, the historian of the Anglo-Saxons, says, they 'had the instruments of chords, and wind-instruments. In the drawings on their MSS. we see the horn, trumpet, flute, and harp, and a kind of lyre of four strings, struck by a plectrum. In one MS. we see a musician striking a four-stringed lyre, while another is accompanying him with two flutes, into which he is blowing at the same time. In the MSS. which exhibit David and three musicians playing together, David has a harp of eleven strings, which he holds with his left hand while he plays with his right fingers; another is playing on a violin or guitar of four strings with a bow; another blows a short trumpet, supported in the middle by a pole, while another blows a curved horn. This is probably the representation of an Anglo-Saxon concert.

'The chord instrument like a violin was perhaps that to which a disciple of Bede alludes, when he expresses how delighted he should be to have 'a player who could play on the cithara, which we call rotæ.' Of the harp, Bede mentions, that in all festive companies it was handed round, that every one might sing in turn. It must have therefore been in very common use.

'Dunstan is also described by his biographer to have carried with him to a house his cythara, 'which, in our language, we call hearpan.' He hung it against the wall, and one of the strings happening to sound untouched, it was esteemed a miracle.

'The organ was in use among the Anglo-Sax-

ons. Cassiodorus and Fortunatus mention the word organ as a musical instrument, but it has been thought to have been a collection of tubes blowed into by the human breath. Muratori has contended that the art of making organs like ours was known in the eighth century only to the Greeks; that the first organ in Europe was the one sent to Pepin from Greece in 756; and that it was in 826 that a Venetian priest, who had discovered the secret, brought it into France. A passage which I have observed in Aldhelm's poem, De Laude Virginum, entirely overthrows these theories; for he, who died in 709, and who never went to Greece, describes them in a manner which shows that he was acquainted with great organs made on the same principle as our own:

> Maxima millenis auscultans organa flabris
> Mulceat auditum ventosis follibus iste
> Quamlibet auratis fulgescant cætera capsis.

This is literally, 'Listening to the greatest organs with a thousand blasts, the ear is soothed by the windy bellows, while the rest shines in the gilt chests.' Dunstan, great in all the knowledge of his day, as well as in his ambition, is described to have made an organ of brass pipes, elaborated by musical measures, and filled with air from the bellows. The bells he made have been mentioned before. About the same time we have the description of an organ made in the church at Ramsey. 'The earl devoted thirty pounds to make the copper pipes of organs, which, resting with their openings in thick order on the spiral winding in the inside, and being struck, on feast days, with the strong blast of bellows, emit a sweet melody, and a far-resounding peal.'

'In 669 Theodore and Adrian, who planted learning among the Anglo-Saxons, also introduced into Kent the ecclesiastical chanting, which Gregory the Great had much improved. From Kent it was carried into the other English churches. In 678 one John came also from Rome, and taught in his monastery the Roman mode of singing, and was directed, by the pope, to diffuse it amongst the rest of the clergy, and left written directions to perpetuate it. Under his auspices it became a popular study in the Saxon monasteries. We have a pleasing proof of the impressive effect of the sacred music of the monks, in the little poem which Canute the Great made upon it. As the monarch, with his queen and courtiers, were approaching Ely, the monks were at their devotions. The king, attracted by the melody, ordered his rowers to approach it, and to move gently while he listened to the sounds which came floating through the air from the church on the high rock before him. He was so delighted by the effect, that he made a poem on the occasion, of which the first stanza only has come down to us. There are many ancient MSS. of the Anglo-Saxon times, which contain musical notes.'

He thus describes, after Muratori, what is known of their mode of *illuminating* books:—'The Anglo-Saxons were fond of beautifying their MSS. with drawings with ink of various colors, colored parchment, and sometimes with gilt letters. The Gospels, Nero, D. 4., exhibit a splendid instance of these ornaments. The Franco-theotisc Gospels, Calig. A. 7., are also highly decorated. Many Saxon MSS. in the Cotton Library exhibit very expensive, and what in those days were thought beautiful, illuminations. The art of doing these ornaments has been long in disuse; but some of the recipes for the materials have been preserved. They prepared their parchment by this rule: 'Put it under lime, and let it lie for three days, then stretch it, scrape it well on both sides, and dry it, and then stain it with the colors you wish.' To gild their skins we have these directions:—'Take the red skin and carefully pumice it, and temper it in tepid water, and pour the water on it till it runs off limpid. Stretch it afterwards, and smooth it diligently with clean wood. When it is dry, take the whites of eggs, and smear it therewith thoroughly; when it is dry, sponge it with water, press it, dry it again and polish it; then rub it with a clean skin, and polish it again, and gild it.'

'Their methods for preparing gold for their gold writing may be mentioned, as they were in fact so many chemical experiments. One method:—'File gold very finely, put it in a mortar, and add the sharpest vinegar; rub it till it becomes black, and then pour it out. Put to it some salt or nitre, and so it will dissolve. So you may write with it, and thus all the metals may be dissolved.'

'The gold letters of the Anglo-Saxon MSS. are on a white embossment, which is probably a calcareous preparation. Modern gilding is made on an oil size of yellow ochre, or on a water size of gypsum, or white oxide of lead, or on similar substances. For gilding on paper or parchment, gold powder is now used as much as leaf gold. Our ancestors used both occasionally. Another method of ancient chrysography:—'Melt some lead, and frequently immerge it in cold water. Melt gold, and pour that into the same water, and it will become brittle. Then rub the gold filings carefully with quicksilver, and purge it carefully while it is liquid. Before you write, dip the pen in liquid alum, which is best purified by salt and vinegar.' Another method:—'Take thin plates of gold and silver, rub them in a mortar with Greek salt or nitre till it disappears. Pour on water, and repeat it. Then add salt, and so wash it. When the gold remains even, add a moderate portion of the flowers of copper and bullock's gall; rub them together, and write and burnish the letters.' Other methods are mentioned, by which even marble and glass might be gilt. These descriptions are taken by Muratori from a MS. of the ninth century, which contains many other curious receipts on this subject.'

Of their *architecture* Mr. Turner observes, 'The arts of life are found to flourish in proportion as their productions are valued and required. When the Anglo-Saxons became converted to Christianity, they wanted monasteries and churches. And this demand for architectural ability would have produced great perfection in the art, if the state of the other arts and sciences had permitted a due cultivation of genius in this; but no single art can attain perfection if

every other be neglected, or if general ignorance enfeeble and darken the mind. Patronage therefore, though it called forth whatever mechanical labor and barbarian taste could fabricate, could not miraculously create taste and regular science. The love of sublimity is more congenial to the rude heroism of infant civilisation, and therefore our ancient architecture often reached to the sublime; but while we admire its vastness, its solidity, and its magnificence, we smile at its irregularities, its discordancies, and its caprice.

'The chief peculiarities of the Anglo-Saxon architecture, of which several specimens, though in fragments, exist, are declared to be a want of uniformity of parts, massy columns, semicircular arches, and diagonal mouldings. Of these the two first are common to all the barbarous architecture of Europe. But the semicircular arches and diagonal mouldings seem to have been more peculiar additions to the Saxon building. That the round arches were borrowed from Roman buildings, is the prevailing sentiment. It is at least a fact, that the Saxons must have seen them among the numerous specimens of the imperial architecture which they found in England.

The universal diagonal ornament, or zig-zag moulding, which is a very distinguishing trait of the Saxon architecture, is found disposed in two ways; one with its point projecting outwards, and the other with its point lying so as to follow the lines which circumscribe it, either horizontal, perpendicular, or circular. On this singular ornament an etymological remark may be hazarded, as it may tend to elucidate its origin. The Saxon word used to denote the adorning of a building is gefrætwian, or frætwan; and an ornament is frætew; but frætan signifies to gnaw or to eat; and upon our recollecting that the diagonal ornament of Saxon building is an exact imitation of teeth, we can hardly refrain from supposing that the ornament was an intended imitation of teeth. Frætwin and frætwung, which they used to signify ornament, may be construed fretwork, or teeth-work. The teeth which the Saxon diagonals represent, are, I believe, marine teeth. If so, perhaps they arose from the stinging of teeth of the large sea animals. We will mention a few of the ancient Saxon buildings we meet with, and show how they are described.

'In 627 Paulinus built the first Christian church, in Northumbria, of wood; it was afterwards rebuilt on a larger scale, and with stone: he also built a stone church at Lincoln. His church at York was not very skilfully erected: for in less than a century afterwards, Wilfrid found its stony offices half destroyed; its roof was permeable to moisture. It had windows of fine linen cloth, or latticed wood-work; but no glazed casements, and therefore the birds flew in and out, and made nests in it. So Bede says of his church at Lincoln, that though the walls were standing, the roof had fallen down.

'In 676 Benedict sought cementarios or masons, to make a church in the Roman manner, which he loved. But the Roman manner seems not to express the Roman science and taste, but rather a work of stone of the large size which the Romans used. It was finished in a year after its foundation. At this period glass-makers were not known among the Saxons. But Benedict had heard of them, and he sent to Gaul for some, to make latticed windows to the porticoes and cænaculum of the church. From those whom he employed the Saxons learned the art.

'In the seventh century Cuthbert built a monastery, which is described. From wall to wall it was of four or five perches. The outside was higher than a standing man. The wall was not made of cut stone, or bricks and cement, but of unpolished stones and turf, which they had dug from the spot. Some of the stones four men could hardly lift. The roofs were made ot wood and clay.

'About 709 Wilfred flourished. He, like many others, had travelled to Rome, and, of course, beheld the most valuable specimens of ancient art. He brought thence some masons and artificers. Though he could not imitate these, he sought to improve the efforts of his countrymen. The church of Paulinus at York he completely repaired. He covered the roof with pure lead, he washed its walls from their dirt, and by glass windows (to use the words of my author), he kept off the birds and rain, and yet admitted light. At Rapon he also erected a church with polished stone, adorned with various columns and porticoes. At Hexham he made a similar building. It was founded deep, and made of polished stones, with many columns and porticoes, adorned with great length and height of walls. It had many windings, both above and below, carried spirally round. It was superior to any edifice on this side of the Alps. In the inside was a stony pavement, on which a workman fell from a scaffold of enormous height.

'In 716 we read of Croyland monastery. The marshy ground would not sustain a stony mass. The king, therefore, had a vast number of piles of oak and alders fixed in the ground, and earth was brought in boats nine miles off to be mingled with the timber and the marsh, to complete the foundation.

'In 969 a church was built. The preceding winter was employed in preparing the iron and wooden instruments, and all other necessaries. The most skilful artificers were then brought. The length and breadth of the church were measured out; deep foundations were laid on account of the neighbouring moisture, and they were strengthened by frequent percussions of the rams. While some workmen carried stones, others made cement, and others raised both aloft by a machine with a wheel. Two towers with their tops soon rose, of which the smaller was visible on the west in front of the church. The larger in the middle with four spires, pressed on four columns, connected together by arches passing from one to the other, that they might not separate. It is supposed that many specimens of ancient Saxon architecture yet remain; as part of St. Peter's at Oxford, part of St. Alban's abbey church, Tickencote church, near Stamford in Lincolnshire, the porch on the south side of Shireburn minster, Barfreston church in Kent, Iffley church, and some others. But the works and delineations of professional men must be consulted on this subject.'

1. *Of England, from the period of the Norman conquest, until the accession of Henry II.*— Nothing could exceed the terror of the English upon the news of the defeat and death of Harold. As soon as William passed the Thames at Wallingford, Stigand, the primate, made submissions to him in the name of the clergy; and before he came within sight of London, all the chief nobility, including Edgar Atheling himself, came and submitted to the conqueror. William readily accepted of the crown upon the terms offered him; viz. that he should govern according to the established customs of the country. He could indeed have made what terms he pleased; but, though in reality a conqueror, he chose rather to be thought an elected king. For this reason he was crowned at Westminster, by the archbishop of York, and took the usual oath, that he would protect and defend the church, observe the laws of the realm, and govern the kingdom with impartiality. The English historians complain of the most grievous oppression by William and his Normans. Whether the conqueror willingly gave the English opportunities of rebelling against him, in order to have a pretence for oppressing them afterwards, is uncertain; but the beginning of his reign cannot justly be blamed. The first disgust against his government was excited among the clergy. William could not avoid rewarding those numerous adventurers who had accompanied him in his expedition. He first divided the lands of the English barons who had opposed him, among his Norman barons: but as these were insufficient, he quartered the rest on the rich abbeys, until some other opportunity of providing for them should offer. This last step was highly resented by the clergy. The whole nation was soon after disgusted, by seeing all the real power of the kingdom placed in the hands of the Normans. The king disarmed the city of London, and other places which appeared most warlike and populous, and quartered Norman soldiers wherever he dreaded an insurrection. Having thus secured England, as he imagined, from any danger of a revolt, he determined to pay a visit to his Norman dominions. His brother Odo, bishop of Bayeux, and William Fitz-Osborne, were appointed regents in his absence; and to secure himself yet farther, he resolved to carry along with him those of the English nobility in whom he had least confidence. William set sail for Normandy in March, 1067; but his absence produced the most fatal consequences. Discontents and murmurings were every where multiplied; secret conspiracies were entered into; hostilities were commenced in many places; and every thing seemed to threaten a speedy revolution. William of Poictiers, a Norman historian, throws the blame entirely on the English. He calls them a fickle and mutinous race, while he celebrates with the highest encomiums the justice and lenity of Odo's and Fitz-Osborne's administration. On the other hand, the English historians tell us, that the regents took all opportunities of oppressing the people, with a view to provoke them to rebellion, and to enrich themselves on their submission. Be this as it may, a secret conspiracy was formed among the English for a general massacre of the Normans, and the vassals of the earl of Coxo actually put him to death because he refused to head them in the enterprise. The conspirators had already taken their final resolution, and fixed on Ash Wednesday, during the time of divine service, for the intended massacre. But the sudden return of William disconcerted all their schemes. Having received intelligence of their bloody purpose, he hastened to England. Such of the conspirators as had been more open in the scheme fled, and this confirmed the accusation against those who remained. William from this period not only lost all confidence in his English subjects, but regarded them as irreconcileable enemies. He raised a vast number of fortresses in the country, until he no longer dreaded the tumultuous efforts of the multitude; and determined to treat the whole as a conquered nation. One of his most decided steps of this kind was the revival of the tax of Dan-gelt, which produced great discontents. The inhabitants of Exeter and Cornwall revolted; but were soon reduced. A more dangerous rebellion broke out in the north; but this was also quashed, and the English became sensible that farther resistance was vain. Their easy submission after the battle of Hastings had inspired the Normans with contempt; their commotions afterwards had rendered them objects of hatred; and they were now deprived of every means which could make them either feared or beloved. Many fled into foreign countries; and among the rest Edgar Atheling, who made his escape to Scotland, with his two sisters, Margaret and Christina. They were well received by Malcolm III., who soon after married Margaret, and received a great number of other exiles with kindness. The people at large, though unable to make any open resistance, did not fail to gratify their resentment against the Normans privately. Seldom a day passed, but the bodies of their assassinated conquerors were found in the woods and high-ways, without any possibility of bringing the authors of their death to justice. This made the Normans themselves begin to wish for tranquillity and security: and several of those entrusted with great commands, desired to be dismissed from the service of the crown. William was obliged to allure many to his service by the largeness of his bounties. The consequences were, fresh exactions from the English, and new insurrections on their part against their masters. The Norman power, however, was too well founded to be finally shaken, and every attempt of the English to regain their liberty served only to rivet their chains. The county of Northumberland, which had been most active in these insurrections, now suffered most severely. The whole of it was laid waste, the houses were burned, the instruments of agriculture destroyed, and the inhabitants dispersed. On this occasion it is said that above 100,000 persons perished either by the sword or famine. The estates of the English gentry were next confiscated, and bestowed on the Normans. Thus most of the ancient and honorable families were reduced to ruin, and the English found themselves totally excluded from honors and preferments. William thus at last broke their spirit and received no

farther trouble from them. He found himself, however, throughout the latter part of his life unhappy through the dissensions of his own family. Robert, his eldest son, surnamed Curthose, from the shortness of his legs, was a prince who inherited all his own bravery and ambition. He had formerly been promised by his father the government of the province of Maine in France, and was declared successor to the dukedom of Normandy. He demanded the fulfilment of several of these promises; but William gave him a flat denial, observing, that 'it was not his custom to throw off his clothes till he went to bed.' Robert declared his resentment; and openly expressed his jealousy of his brothers William and Henry. An open rupture soon occurred. The two young princes, one day, sportively threw water upon him as he passed through the court; and Robert inflamed by one of his favorites construed this frolic into a studied indignity. He drew his sword, and ran up stairs with an intent to take revenge. The whole castle was quickly in a tumult; and it was not without difficulty that the king himself could appease it. He could not, however, allay the animosity which from that moment prevailed in his family. Robert, attended by several of his confederates, withdrew to Rouen that night, hoping to surprise the castle; but his design was defeated by the governor. The popularity of the prince, however, engaged all the young nobility of Normandy, as well as of Anjou and Brittany, to espouse his quarrel; even his mother is supposed to have supported him in his rebellion by secret remittances. The contest continued for several years; and William was at last obliged to have recourse to England for support against his own son. Accordingly he led an army of Englishmen over to Normandy, where he soon compelled Robert and his adherents to quit the field, and was reinstated in his dominions. Robert then took shelter in the castle of Gerberoy, which the king of France had provided for him, and where he was shortly after besieged by his father. As the garrison was strong, they made a gallant defence, and many skirmishes and duels were fought under its walls. In one of these the king and his son happened to meet; but being both concealed by their helmets, they attacked each other with fury. The young prince wounded his father in the arm, and threw him from his horse. The next blow would probably have put an end to his life had he not called for assistance. Robert instantly recognised his father's voice, leaped from his horse and raised him from the ground. He then prostrated himself, it is said, asked pardon for his offences, and promised for the future a strict adherence to filial duty. The king was not so easily appeased; and no doubt his resentment was heightened by the disgrace of being overcome. He therefore gave his malediction to his son; and returned to his own camp on Robert's horse. After some recollection however, he became reconciled to the prince and took him with him into England.

William returned in 1081; and being now freed from his enemies at home and abroad directed the formation of the celebrated DOMESDAY-BOOK. See that article. He reserved a very ample revenue for the crown; and, in the general distribution of land among his followers, kept possession of no fewer than 1400 manors in different parts of the country. No king of England was ever so opulent; none was able to support the splendor of a court to such a degree; none had so many places of trust and profit to bestow; and consequently none ever had more implicit obedience paid to his commands. He delighted greatly in hunting; and, to indulge himself in this with the greater freedom, he depopulated Hampshire for thirty miles, making the wretched outcasts of the villages no compensation for such an injury. In the time of the Saxon kings all noblemen had a right to hunt in the royal forests; but William appropriated the whole of these to himself, and published the first severe game laws. The killing of a boar, a deer, or even a hare, was punished with the loss of the delinquent's eyes; while the killing of a man might be atoned for by paying a moderate fine. The riches of his ministers, as we have intimated, were in proportion. Odo, bishop of Bayeux, William's brother, was so rich that he resolved to purchase the papacy. For this purpose, during the king's absence he equipped a vessel in the Isle of Wight, on board of which he sent immense treasures, and prepared for his embarkation. He was detained, however, by contrary winds, till William, being informed of his designs, resolved to prevent the exportation of so much wealth. Returning from Normandy, he came to England at the very time his brother was about to go on board. He immediately ordered him to be made prisoner; but his attendants, respecting the bishop's character, scrupled to execute his commands; so that the king was obliged to seize him with his own hand. Odo appealed to the pope: but the king replied, that he did not seize him as bishop of Bayeux, but as earl of Kent: and in that capacity, demanded an account of his administration. He was therefore sent prisoner to Normandy; and, notwithstanding all the threats of Gregory VII., was detained in custody during the remainder of William's reign. Soon after this, William experienced a severe blow in the death of his queen Matilda; and, almost at the same time, received information of a general insurrection in Maine. Upon his arrival on the continent, he found that the insurgents had been secretly excited by the king of France, who took all opportunities of lessening the Norman power. His indignation on this account was also increased by the accounts he received of some railleries thrown out against him by the French monarch. William, who was become corpulent, had been detained in bed by sickness; and Philip was heard to say, that he only lay in of a big belly. This so provoked the English monarch that he sent him word, he would soon be up, and at his churching present such a number of tapers as would set the kingdom of France in a flame. He accordingly levied a powerful army; and, entering the Isle of France, destroyed every thing with fire and sword. He took the town of Mante, and reduced it to ashes. But a period was now to be put at once to the conquests and the life of this great warrior. His horse happening in this neighbourhood to set his fore feet on some hot ashes, plunged violently, and the king was thrown

forward, and bruised on the pommel of the saddle. Being advanced in years, he felt apprehensive of the consequences, and ordered himself to be carried in a litter to the monastery of St. Gervaise. Here his illness increased; and, becoming sensible of the approach of death, he discovered great remorse on the review of his life, and endeavoured to make compensation by presents to churches and monasteries. He also gave orders for the liberation of several English noblemen, and was prevailed upon to restore his brother Odo, against whom he was much incensed. He left Normandy and Maine to his eldest son Robert. He wrote to Lanfranc, the primate, to crown William king of England. To Henry he bequeathed nothing but the possessions of his mother Matilda; but foretold, that one day he would surpass both his brothers in power and opulence. He expired on the 9th of September 1087, in the sixty-third year of his age, in the twenty-first of his reign over England, and fifty-fourth over that of Normandy.
